On Isis and Osiris is a rather long treatise on Egyptian symbolism, interesting chiefly to students of Egyptology. It gives an exposition of the strange myths and superstitions of this ancient solar cult, including a full account of the great antagonist of Osiris, Typhon, or the Egyptian Satan. Plutarch thus lays down the Zoroastrian theory of good and bad agencies (§ 45): "if nothing can happen without cause, and good cannot furnish cause for evil, it follows that the nature of evil, as of good, must have an origin and principle of its own."

On the Cessation of Oracles is a dialogue, discussing the reasons why divine inspiration seemed to be withdrawn from the old seats of prophetic lore. The real reason of their decline in popularity is probably very simple; when the Greek cities became Roman provinces the fashion of consulting oracles fell off, as unsuited to the more practical influences of Roman thought and Roman politics. The question is discussed whether there are such intermediate beings as dæmons, who according to Plato communicate the will of the gods to men, and the prayers and vows of men to the gods.

The possibility of a plurality of worlds is entertained, and of the planets being more or less composed of the

essence of the five elements, fire, ether, earth, air, and water (§ 37). The whole treatise is metaphysical, but it concludes with remarks on the exhalations at Delphi having different effects on different people and at different times. The ancient notion doubtless was that the vapor was the breath of some mysterious being sent up from the under-world.

On the Pythian Responses, why no longer given in Verse, is also a dialogue, the first part of which is occupied mainly with conversation and anecdotes about the statues and other offerings at Delphi. It is rather an amusing essay, and may be regarded as a kind of appendix to the last. The theory propounded (§ 24) is that verse was the older vehicle of philosophy, history, and religion, but that plain prose has become the later fashion, and therefore that oracles are now generally delivered "in the same form as laws speak to citizens, kings reply to their subjects, and scholars hear their teachers speak." Discredit too was brought on the verse-oracle by the facility with which it was employed by impostors (§ 25). Moreover, verse is better suited to ambiguity, and oracles now-a-days have less need to be ambiguous (§ 28).

On the E at Delphi is an inquiry why that letter or symbol was written on or in the Delphic temple. Some thought it represented the number five, others that it introduced the inquiry of oracle-seekers, *If so-and-so was to be done*; while one of the speakers, Ammonius, decides that it means *EI*, "thou art," an address to Apollo containing the predication of existence (§ 17).

On the Face on the Moon's Disk is a long and curious if somewhat trifling speculation, yet not without interest from its calculations of the sizes and the distance from earth of the sun and moon (§ 10), and from the contrast between ancient lunar theories and modern mathematics. The cause of the moon's light, its peculiar color, the possibility of its being inhabited, and many kindred questions are discussed in this dialogue, the beginning and end of which are alike abrupt. Some of the "guesses at truth" are very near the mark, as when it is suggested (§§ 21-2) that the moon, like the earth, contains deep recesses into which the sun's light does not descend, and the appearance of the "face" is nothing but the shadows of streams or of deep ravines.

On the late Vengeance of the Deity is a dialogue consequent on a supposed lecture by Epicurus. An objection is raised to the ordinary dealings of providence, that long delayed punishment encourages the sinner and disappoints the injured, the reply to which is (§ 5) that the god sets man an example to avoid hasty and precipitate resentment and that he is willing to give time for repentance (§ 6). Moreover, he may wish to await the birth of good progeny from erring parents (§ 7). Another fine reflection is that sin has its own punishment in causing misery to the sinner, and thus the longer the life the greater is the share of misery (§ 9). The essay concludes with a long story about one Thespius, and the treatment which he saw, during a trance, of the souls in the other world.

On Fate discusses the law of chance as against the overruling of providence. This treatise ends abruptly; the point of the argument is that both fate and providence have their due influence in mundane affairs (§ 9), and that all things are constituted for the best.

On the Genius of Socrates is a long essay, and, like so many of the rest, in the form of a dialogue. The experiences of one Timarchus, and his supernatural visions in the cave of Trophonius, are related at length in the Platonic style (§ 22), and the true nature of the *δαίμονες* is revealed to him. They are the souls of the just, who still retain regard for human affairs and assist the good in their efforts after virtue (§ 28). The dialogue ends with an interesting narrative of the concealment of Pelopidas and some of the Theban conspirators against the Spartans in the house of Charon.

On Exile is a fine essay, rendered the more interesting from its numerous quotations from the poets, including several from the *Phænissæ*. Man is not a plant that grows only in one soil; he belongs to heaven rather than to earth, and wherever he goes there are the same sun, the same seasons, the same providence, the same laws of virtue and justice (§ 5). There is no discredit in being driven from one's country; Apollo himself was banished from heaven and condemned to live for a time on earth (§ 18).

The Consolation to his Wife, on the early death of their only daughter, Timoxena (§ 7), is a feeling and sensible exhortation to moderate her grief.

Nine books of *Symposiaca* extend to a great length, discussing inquiries (*προβλήματα*) on a vast number of subjects. The general treatment of these, in which great literary knowledge is displayed, is not unlike the style of Athenæus. It is, of course, impossible here to give any summary of the questions propounded.

The Amorous Man is a dialogue of some length, describing a conversation on the nature of love, held at Helicon, pending a quinquennial feast of the Thespians, who specially worshipped that deity along with the Muses. It is amply illustrated by poetical quotations. In § 24 mention is made of the emperor Vespasian. It is followed by a short treatise entitled *Love Stories*, giving a few narratives of sensational adventures of lovers.

Short Sayings (*ἀποφθίγματα*), dedicated to Trajan, extend to a great length, and are divided into three parts: (1) of kings and commanders (including many Roman); (2) of Spartans; (3) of Spartan women (a short treatise on Spartan institutions being interposed between the last two). The names of the authors are added, and to some of them a large number of maxims are attributed. Many are terse, shrewd, wise, or pointed with strong common sense; but a good many seem to us now somewhat commonplace.

A rather long treatise *On the Virtues of Women* contains a series of narratives of noble deeds done by the sex in times of danger and trouble, especially from "tyrants." Many of the stories are interesting, and the style is easy and good.

Another long and learned work bears the rather obscure title *Κεφαλαίων καταγραφή*. It is generally known as *Questiones Romanæ et Græcæ*, in two parts. In the former, which contains one hundred and thirteen headings, the inquiry (on some matter political, religious, or antiquarian) always commences with *διὰ τί*, usually followed by *πότερον*, with alternative explanations. In the *Greek Questions* the form of inquiry is more often *τίς* or *τίνας*, not followed by *πότερον*. This treatise is of great interest and importance to classical archæology; though the inquiries seem occasionally trifling, and sometimes the answers are clearly wrong.

Parallels are a series of similar incidents which occurred respectively to Greeks and Romans, the Greek standing first and the Roman counterpart following. Many of the characters are mythological, though Plutarch regards them as historical.

On the Fortune of the Romans discusses whether, on the whole, good luck or valor had more influence in giving the Romans the supremacy. This is followed by two discourses (*λόγοι*) on the same question as applicable to the career of Alexander the Great, *Whether the Athenians were more renowned for War or for Wisdom?* The conclusion is (§ 7) that it was not so much by the fame of their poets as by the deeds of their heroes that Athens became renowned.

Gryllus is a most amusing dialogue, in which Circe, Ulysses, and a talking pig take part. Ulysses wishes that all the human beings that have been changed by the sorceress into bestial forms should be restored; but "piggy" is quite opposed to the return, arguing that in moral virtues, such as true bravery, chastity, temperance, and general simplicity of life and contentment, animals are very far superior to man.

Whether Land Animals or Water Animals are the Cleverer is a rather long dialogue on the intelligence of ants, bees, elephants, spiders, dogs, etc., on the one hand, and the crocodile, the dolphin, the tunny, and many kinds of fish, on the other. This is a good essay, much in the style of Aristotle's *History of Animals*.

On Flesh-Eating, in two orations, discusses the origin of the practice, viz., necessity, and makes a touching appeal to man not to destroy life for mere gluttony (§ 4). This is a short but very sensible and interesting argument. *Questions on Plato* are ten in number, each heading subdivided into several speculative replies. The subjects are for the most part metaphysical; the essay is not long, but it concerns Platonists only. *Whether Water or Fire is more Useful* is also short; after discussing the uses of both elements it decides in favor of the latter, since nothing can exceed in importance the warmth of life and the light of the sun.

On Primary Cold is a physical speculation on the true nature and origin of the quality antithetical to heat. *Physical Reasons* (*Questiones Naturales*) are replies to inquiries as to why certain facts or phenomena occur; e.g., "Why is salt the only flavor not in fruits?" "Why do fishing-nets rot in winter more than in summer?" "Why does pouring oil on the sea produce a calm?" *On the Opinions Accepted by the Philosophers*, in five books, is a valuable compendium of the views of the Ionic school and the Stoics on the phenomena of the universe and of life. *On the Ill-nature of Herodotus* is a well-known critique of the historian for his unfairness, not only to the Boeotians and Lacedæmonians, but to the Corinthians and other Greek states. It is easy to say that this essay "neither requires nor merits refutation"; but Plutarch knew history, and he writes like one who thoroughly understands the charges which he brings against the historian. The *Lives of the Ten Orators*, from Antiphon to Dinarchus, are biographies of various length, compiled, doubtless, from materials now lost.

Two rather long essays, *Should a Man Engage in Politics when he is no longer Young*, and *Precepts for Governing* (πολιτικά παραγγέλματα), are interspersed with valuable quotations. In favor of the former view the administrations of Pericles, of Agesilaus, of Augustus, are cited (§ 2), and the preference of older men for the pleasures of doing good over the pleasures of the senses (§ 5). In the latter, the true use of eloquence is discussed, and a contrast drawn between the brilliant and risky and the slow and safe policy (§ 10). The choice of friends, and the caution against enmities, the dangers of love, of gain, and of ambition, with many topics of the like kind, are sensibly advanced and illustrated by examples.

Besides the numerous works that have come down to us, Plutarch speaks of a work called *Atria*, the same title with the lost poem of Callimachus (*Romulus*, § 15).

The *Libres* have often been translated; the most popular version into English is that by John and William Langhorne; more recently many of the Roman lives have been translated, with notes, by the late Mr. George Long. An excellent and convenient edition of the Greek text, in 5 vols. 12 mo., has been published in the Teubner series by Carl Sintenis. It seems strange that no modern edition of the *Opéra Moralia* exists, and that the student has to fall back on the old-fashioned volumes of Wyttenbach (6 vols. 4to. Oxford, also printed in 8 vo.), Reiske (in 12 vols. 8vo.), and Hutten (14 vols. 8 vo.). Whether there is any hope of Rudolph Hercher's single volume (1872) in the Teubner series being followed by others, we have no information. (F. A. P.)

PLUTO, the god of the dead in Greek mythology. His oldest name was Hades (*Αἰδης*, *Αἰδης*, *Ἄδης*), "the Unseen"; the name Pluto (*Πλούτων*) was given him as the bestower of the riches (*πλοῦτος*) of the mine, and in ordinary language it ousted the dread name of Hades, which was, however, retained in poetry. He was the son of Cronus and Rhea, and brother of Zeus and Poseidon. Having deposed Cronus, the brothers cast lots for the kingdoms of the heaven, the sea, and the infernal regions, and Pluto obtained the infernal regions, which from their ruler were afterwards known as Hades. The "house of Hades" was a dark and dreadful abode deep down in the earth. How literally the god was supposed to dwell underground is shown by the method of invoking him, which was by rapping on the ground to attract his attention. According to another view the realm of Hades was in a land beyond the ocean in the far west, which to the Greek was always the region of darkness and death, as the east of light and life. This is the view of Hades presented in the *Odyssey*. Ulysses sails all day with a north wind, and at sunset reaches a land at the limits of ocean. Here, wrapped in mist and cloud, dwell the Cimmerians, who never see the sun. He lands, and moving along the shore he calls the ghosts of the departed to meet him. In the description of the Cimmerians we have perhaps a traveller's tale of the long dark winters of the north. Besides this gloomy region, we find in another passage of the *Odyssey* (iv. 561 sq.) a picture of Elysium, a happy land at the ends of the earth where rain and snow fall not, but the cool west wind blows and men live at ease. After Homer this happy land, the abode of the good after death, was known as the Island of the Blest, and these in later times were identified with Madeira and the Canary Islands.¹ But in the oldest Greek mythology the "House of Hades" was a place neither of reward nor punishment; it was simply the home of the dead, good and bad alike, who led a dim and shadowy reflection of life on earth.

¹ The conception of the land of the dead, whether in the far west or beneath the earth, might be paralleled from the beliefs of many savage tribes. The Samoan Islanders unite the two conceptions; the entrance to their spirit-land is at the westernmost point of the westernmost island, where the ghosts descend by two holes into the under-world. Long ago the inhabitants of the French coast of the English Channel believed that the souls of the dead were ferried across to Britain, and there are still traces of this belief in the folk-lore of Brittany (Tylor, *Primitive Culture*, ii. p. 64; Grimm, *Deutsche Mythologie*, ii. p. 694). In classical mythology the underground Hades prevailed over the western. It was an Etruscan custom at the foundation of a city to dig a deep hole in the earth, and close it with a stone; on three days in the year this stone was removed, and the ghosts were then supposed to ascend from the lower world. In Asia Minor caves filled with mephitic vapors or containing hot springs were known as Plutonia or Charonia. The most famous entrances to the under-world were at Tænarus in Laconia, and at the Lake Avernus in Italy.

The differentiation of this "home of Hades" into a heaven and a hell was the result of progressive thought and morality. Pluto was himself simply the ruler of the dead; in no sense was he a tempter and seducer of mankind like the devil of Christian theology. Indeed the very conception of a devil, as a principle of evil in continual conflict with God or the principle of good, is totally foreign to Greek mythology, as it was also to Indian and Teutonic mythology. Pluto was certainly depicted as stern and pitiless, but he was so only in discharge of his duty as custodian of the dead. But even Pluto once melted at the music of Orpheus when he came to fetch from the dead his wife Eurydice. The cap of Hades, like the *Nebelkappe* of German mythology, rendered its wearer invisible; as a sort of thick cloud it was the reverse of the nimbus or halo of the heavenly gods. While the victims sacrificed to the latter were white, those offered to Pluto were black. His wife was Proserpine (Persephone), daughter of Demeter (Ceres), whom he carried off as she was gathering flowers at Enna in Sicily. Like the Greeks, the ancient Italians believed that the souls of the dead dwelt underground; in Latin the names for the god of the dead are Orcus and Father Dis, but the Greek name Pluto also frequently occurs. But, while Orcus was rather the actual slayer, the angel of death, Father Dis was the ruler of the dead, and thus corresponded to Pluto. Their names also correspond, Dis being a contraction for Dives, "wealthy." The Etruscan god of death was represented as a savage old man with wings and a hammer; at the gladiatorial games of Rome a man masked after this fashion used to remove the corpses from the arena. In Romanesque folklore Orcus has passed into a forest-elf, a black, hairy, man-eating monster, upon whose house children lost in the woods are apt to stumble, and who sometimes shows himself kindly and helpful. He is the Italian *orco*, the Spanish *ogro*, the English *ogre*.

PLUTUS (*πλοῦτος*, "wealth"), the Greek god of riches, whom Demeter bore to Iasion "in the fat land of Crete." He enriched every one whom he fell in with. According to Aristophanes, he was blinded by Zeus in order that he might not enrich the good and wise alone. At Thebes there was a statue of Fortune holding the child Plutus in her arms; at Athens he was similarly represented in the arms of Peace; at Thespiae he was represented standing beside Athene the Worker. Elsewhere he was represented as a boy with a cornucopia. He is the subject of one of the extant comedies of Aristophanes.

PLYMOUTH, a municipal and parliamentary borough and seaport town of Devonshire, England, is picturesquely situated on Plymouth Sound in the southwest corner of the county, at the confluence of the Tamar and Plym, 44 miles southwest of Exeter.

Environs of Plymouth.

With the borough of Devonport and the township of East Stonehouse it forms the aggregate town known as the "Three Towns." There is railway communication by means of the Great Western and Southwestern lines, and by several branch lines connected with these systems. The defences of the town,

in addition to the citadel, an obsolete fortification built by Charles II., on the site of an older fort, consist of a most elaborate chain of forts of great strength mounted with guns of the heaviest calibre, and form-

ing a complete line of defence round the whole circumference both landwards and seawards. The streets are for the most part narrow and crooked, and the houses very irregular both in style of architecture and in height. Great improvements have, however, recently taken place. The more ancient part of the town near the water-side has been much altered, and a number of model dwellings have also lately been erected. In the principal thoroughfares there are numerous handsome shops and other imposing business establishments. Among the most important of the public buildings is the Guildhall, completed in 1874 at a cost of £56,000 [\$272,160], a fine group in the Gothic style of the 13th century, with a lofty tower, and containing the town-hall with a fine organ and a series of historical windows, a police court and offices, a sessions and other court rooms, and the council chamber and municipal offices. The new post-office in Westwell Street was erected at a cost of £12,000 [\$58,320]. The market, dating from 1804, and occupying about three acres in the centre of the town, is in course of reconstruction. A fine clock-tower, erected by the corporation, stands at the junction of George Street and Union Street.

The parish church of St. Andrews, some portions of which date from about 1430, has undergone alterations and improvements at different periods, and in 1874-75 was completely restored under the direction of the late Sir G. G. Scott. The tower, built in 1460, contains a fine peal of bells. The church of Charles the Martyr was begun in 1640, when the parish was divided, but owing to the Civil War was not completed till 1657. Of the other more modern parish churches there are none of special interest. The town is the seat of a Roman Catholic bishopric, the cathedral of which, a good building in the Early English style, was opened in 1858 at a cost of £10,000 [\$48,600]. Attached to it is the convent of Notre Dame, and several other religious houses and chapels. The Athenæum (1812) is the home of the Plymouth Institution and the Devon and Cornwall Natural History Society. In connection with it there are a lecture hall, a museum, art gallery, and a small but select scientific library. The Plymouth Proprietary Library (1812) has a good selection of books in general literature, and the building also contains the library of the Plymouth Incorporated Law Society and the Cottonian

Plan of Plymouth.

collection, which includes many relics of Sir Joshua Reynolds and a number of his pictures. The Free Public Library, established in 1876, at present occupies the old Guildhall. The principal educational establishments are the Western College for the training of students for the ministry of the Independent denomination; the Plymouth College, a high school for boys; the High School for Girls; the Corporation Grammar School, founded in 1572; the Public School, established in 1809 (one of the largest public schools in England); the Gray Coat School; the Blue Coat School; the Orphan's Aid; Lady Rogers's School; the Orphan Asylum; and the Household of Faith founded by the well known Dr. Hawker. The Plymouth school board has nine schools in full operation; and each of the principal parishes has also its parochial day school. The charitable institutions em-

brace the South Devon and East Cornwall Hospital, for which a fine range of buildings has lately been erected; the Devon and Cornwall Female Orphan Asylum (1834); the Penitentiary and Female Home (1833); the Royal Eye Infirmary (1821); the South Devon and Cornwall Institution for the Blind (1860, new building erected 1876), and various other philanthropic societies. The only public recreation ground of any extent is the Hoe Park, 18 acres, a fine promenade sloping gradually to the sea, attached to which is a handsome promenade pier. On the Hoe a statue in bronze, by Boehm, of Sir Francis Drake was unveiled in 1884. Smeaton's lighthouse has been removed from the reef on which it stood for one hundred and twenty years, and is now a prominent object on the Hoe. The view from the Hoe includes Mount Edgecumbe with its beautifully wooded slopes, the

Cornwall hills, the Dartmoor hills on the northeastern horizon, and Eddystone lighthouse far away over the waters of the Channel.

Plymouth not only holds a leading position in the country as a naval station, but is the centre of the growing trade of Devonshire and Cornwall, and is also becoming a holiday centre and health resort. To the south of the town is the Sound, protected by the magnificent breakwater, within the limits of which and the harbors connected with it the whole British navy might find a safe anchorage. The western harbor, known as the Hamoaze, at the mouth of the river Tamar, is devoted almost exclusively to the requirements of the royal navy, as along its banks are the dockyard, the Keyham factory, the arsenal, and other Government establishments (see *DEVONPORT*, vol. vii. 120; and *DOCKYARDS*, vol. vii. 274). The eastern harbor, Cattewater with Sutton Pool, now protected by a new breakwater at Mount Batten, is the anchorage ground for merchant shipping. Commodious dock accommodation is provided at the Great Western Docks, Millbay, between Plymouth and Stonehouse, opened in 1857, and comprehending a floating basin over 13 acres in extent with a depth of 22 feet at spring tides, a tidal harbor of 35 acres, and a graving dock. The port has an extensive trade with America, the West Indies, Mauritius, Africa, and the Baltic ports, as well as an extensive coasting trade. It is the starting point for many of the emigrant ships for Australia, New Zealand and British America. The chief exports are minerals, including copper, lead, tin, granite and marble. There is also some trade in pilchards and other fish. The imports are chiefly agricultural produce and timber. The total number of vessels that entered the port in cargo and in ballast in 1883 was 3852, of 843,227 tons, the number that cleared 3443, of 754,318 tons. Plymouth has few manufactures, the principal being biscuits, black-lead, candles, manures, soap, starch, sugar, lead, and the celebrated Plymouth gin. The principal industries are connected with shipbuilding and the fisheries. According to the Act of 1835, the borough is divided into six wards, and is governed by a mayor, twelve aldermen, and thirty-six councillors. The water-works are under the control of the corporation, but the gas-works are in the hands of a company. The population of the municipal borough (area 1468 acres) in 1871 was 68,758, and in 1881 it was 73,794. The population of the parliamentary borough (area 2061 acres) in the same years was 70,091 and 76,080. It returns two members to parliament.

The Hoe at Plymouth is claimed to be the high rock from which, according to Geoffrey of Monmouth, Corineus the Trojan hurled the giant Goemagot into the sea, and at an early period there was cut out in the ground at the Hoe the likeness of two figures with clubs in their hands, which for many years was renewed by the corporation, and was in existence till the erection of the citadel about 1671. Both British and Roman remains have been found in the neighborhood, the most important being those of a Romano-British cemetery discovered in 1864 during the construction of Fort Stamford. In Domesday it occurs as Sutone, and afterwards it was divided into the town of Sutton Prior, the hamlet of Sutton Valletort, and the tithing of Sutton Ralph, a part of it having been granted to the Norman family of Valletort, while the greater part belonged to the priory of Plympton. About 1253 a market was established, and in 1292 the town first returned members to parliament. In the 14th century it was frequently the port of embarkation and of disembarkation in connection with expeditions to France. It suffered considerably at the hands of the French in 1338, 1350, 1377, 1400, and 1402, the Bretons on the last occasion destroying six hundred houses. In 1412 the inhabitants petitioned for a charter, but for a long time their application was opposed by the prior and convent of Plympton. In 1439 a charter was, however, at last granted by Henry VI., defining the limits of the town, permitting the erection of walls and defences, allowing the levying of dues on shipping for the purpose of such buildings and their maintenance, and directing the institution of a corporate body under the title of the "mayor and commonalty of the borough of Plymouth." Leland speaks (1540-47) of Plymouth harbor as being chained across in times of necessity,

and of an "old 'castel quadrate' between the town and the sea." A small fragment of one of the outer works of this castle still stands at the foot of Lambhay Street. During the rebellion of 1548-49 the town suffered severely at the hands of the insurgents, and according to Westcote the "evidences" of the borough were burnt. Under Elizabeth it rose to be the foremost port of England, and Camden, who visited the town about 1588, states that "though not very large its name and reputation is very great among all nations." In the discovery of the new world it played a part of prime importance. Martin Cockram, a native of the town, sailed with Sebastian Cabot when he touched the coast of America in 1497. Sir John Hawkins and his father William were natives of the town, and in 1571 Sir John was returned member of parliament for the borough. In 1572 Sir Francis Drake left the port for the West Indies, and in 1577 he set out from it on his voyage "about the earth." He was elected mayor of the town in 1581, and in 1592-93 represented it in parliament. Sir Humphrey Gilbert, who was M.P. for Plymouth in 1571, had in 1578 received from Queen Elizabeth letters patent for a colony in America; but, after setting out in 1579, he was compelled to return with the loss of his principal ship. In 1583 he sailed again from Plymouth (see GILBERT). In 1585 Drake again sailed from Plymouth for the West Indies, bringing back on his return the remnant of Raleigh's Virginian colony. The port supplied seven ships against the Spanish Armada, and it was in the sound that the English fleet of 120 sail awaited the sighting of the Spaniards. In 1590 Drake was successful in the oft attempted task of bringing in a stream of fresh water for the use of the town, from the river Meavy near Sheepstor, Dartmoor. He and Sir John Hawkins sailed from Plymouth on their last voyage in 1595, both dying at sea in the following year. Many other expeditions from Drake's time to the present have been despatched from this port, which was the last at which the Pilgrim Fathers touched when they set sail for America. Plymouth was throughout nearly the whole Civil War closely invested by the Royalists, and was the only town in the west of England which never fell into their hands. The town was one of the first to declare for William of Orange. It was in 1691, during his reign, that the dockyard was commenced. The "local literature" of Plymouth is singularly rich and comprehensive. It has also a connection with many men of great eminence. Sir Joshua Reynolds, born at Plympton, first practiced his art in the town, and its native artists are represented by Sir Charles Lock Eastlake, James Northcote, Benjamin Robert Haydon, and Samuel Prout. Besides Sir John Hawkins and other celebrated seamen, it has also given birth to Sir William Snow Harris, Dr. James Yonge, Dr. John Kitto, Dr. S. P. Tregelles, Dr. Robert Hawker, N. T. Carrington the Dartmoor poet, Mortimer Collins, and Sir R. P. Collier.

See Histories by Worth, 1871, and by Jewett, 1873; Rowe, *Ecclesiastical History of Old Plymouth*; *The Western Antiquary*; Worth, *The Three Towns Bibliotheca*.

PLYMOUTH, a township and village of the United States, the shire-town of Plymouth county, Massachusetts, and a port of entry on Cape Cod Bay,—the village lying at the terminus of a branch of the Old Colony Railroad, 37 miles south-southeast of Boston. The main interest of Plymouth is historical, and centres in the fact that it was the first settlement of the Pilgrim Fathers of New England, who landed December 21 (N.S.), 1620, on the rock now covered by a handsome granite canopy in Walter Street. Leyden Street, so called in memory of the Dutch town where the exiles had stopped for a season, is the oldest street in New England. The houses and general appearance of Plymouth are, however, thoroughly modern. Pilgrim Hall (which is built of granite and measures 70 feet long by 40 feet wide) was erected in 1824-25 by the Pilgrim Society constituted in 1820; it contains a public library and many relics of the fathers—including Miles Standish's sword and Governor Carver's chair. The corner stone of a national monument to the Pilgrims was laid August 1, 1859, on a high hill near the railroad station; 1500 tons of granite were used for the foundation; and a pedestal 45 feet high is surrounded by statues 20 feet high of Morality, Law, Education, and Freedom, and bears a colossal statue of Faith, 36 feet high, holding a Bible in her right hand (the largest granite statue in the world). Burying Hill was the site of the embattled church erected in 1622, and contains many ancient tombstones and the

foundations of the watchtower (1643) now covered with sod. Cole's Hill is the spot where half of the "May-flower" pilgrims found their rest during the first winter. Five of their graves were discovered in 1855 while pipes for the town water-works were being laid, and two more (now marked with a granite slab) in 1883. The bones of the first five are deposited in a compartment of the canopy over the "Forefathers' Rock." A town hall (1749), the county court-house, and the house of correction are the main public buildings of Plymouth. The population of the township was 4758 in 1830, 6024 in 1850, 6238 in 1870, 7093 in 1880, and 7500 in 1884. Manufactures of sail-duck, cotton-cloth, tacks, nails, plate-iron, rolled zinc and copper rivets, hammers, etc., are carried on; the cordage factories are among the largest and most complete works of the kind in the world.

PLYMOUTH, a borough of the United States, in Luzerne county, Pennsylvania, on the Bloomsburg division of the Delaware, Lackawanna, and Western Railroad, 8 miles from Wyoming, is a flourishing coal-mining town, which increased its population from 2648 in 1870 to 6065 in 1880. At Plymouth junction, 2 miles to the northeast, a branch line to Wilkesbarre connects with the Central Railroad.

PLYMOUTH BRETHREN (BRETHREN, OR CHRISTIAN BRETHREN) are a sect of Christians who received the name in 1830 when the Rev. J. N. Darby induced many of the inhabitants of Plymouth to associate themselves with him for the promulgation of opinions which they held in common. Although small Christian communities existed in Ireland and elsewhere calling themselves *Brethren* and holding similar views, the accession to the ranks of Mr. Darby so increased their numbers and influence that he is usually reckoned the founder of Plymouthism. Darby (born in Nov. 1800, in London; graduated at Trinity College, Dublin, in 1819; died April 29, 1882 at Bournemouth) was a curate in the Episcopal Church of Ireland until 1827, when he felt himself constrained to leave the Established Church; betaking himself to Dublin, he became associated with several devout people who refused all ecclesiastical fellowship, met stately for public worship, and called themselves the Brethren. In 1830 Darby at Plymouth won over a large number of people to his way of thinking, among whom were the Rev. Benjamin Wills Newton, who had been a clergyman of the Established Church of England; the Rev. James L. Harris, a Plymouth clergyman; and the well-known Biblical scholar Dr. Samuel Prideaux Tregelles. The Brethren started a newspaper, *The Christian Witness*, continued under the names *The Present Testimony* (1849) and *The Bible Treasury* (1856), with Harris as editor and Darby as the most important contributor. During the next eight years the progress of the sect was rapid, and communities of the brethren were to be found in many of the principal towns in England.

In 1838 Darby, after a short stay in Paris, went to reside in French Switzerland, and found many disciples. Congregations were formed in Geneva, at Lausanne, where most of the Methodist and other dissenters joined the Brethren, at Vevey, and elsewhere in Vaud. His opinions also found their way into Germany, German Switzerland, Italy, and France; but French Switzerland has always remained the stronghold of Plymouthism on the Continent, and for his followers there Mr. Darby wrote two of his most important tracts, *Le Ministère considéré dans sa Nature*, and *De la Présence et de l'Action du S. Esprit dans l'Eglise*. The revolution in the canton Vaud, instigated by the Jesuits in 1845, brought persecution to the Brethren in the Canton and in other parts of French Switzerland, and Darby felt his own life insecure there.

He returned to England, and his reappearance was accompanied by divisions among the Brethren at home. These divisions began at Plymouth. Mr. B.

Wills Newton, at the head of the community there, was accused of departing from the testimony of the Brethren against an official ministry, and of reintroducing the spirit of clericalism. Unable to detach the congregation from the preacher, Darby began a rival and separate assembly. The majority of the Brethren out of Plymouth supported Darby, but a minority kept by Newton. The separation became wider in 1847 on the discovery of supposed heretical teaching by Newton. In 1848 another division took place. The Bethesda congregation at Bristol, where Mr. George Müller was the most influential member, received into communion several of Newton's followers and justified their action. A large number of communities approved of their conduct; others were strongly opposed to it. Out of this came the separation into Neutral Brethren led by Müller, and Exclusive Brethren or Darbyites, who refused to hold communion with the followers of Newton or Müller. The exclusives, who were the more numerous, suffered further divisions. An Irish clergyman named Cluff had adopted the views of Mr. Pearsall Smith, and when these were repudiated seceded with his followers. The most important division among the exclusives came to a crisis in 1881, when Mr. William Kelly and Mr. Darby became the recognized leaders of two sections who separated on some point of discipline. There are therefore at least five official divisions or sects of Plymouthists: (1) the followers of Mr. B. Wills Newton; (2) the Neutrals, who incline to the Congregationalist idea that each assembly should judge for itself in matters of discipline, headed by Mr. George Müller; (3) the Darbyite Exclusives; (4) the Exclusives who follow Mr. Kelly; and (5) the followers of Mr. Cluff. The fundamental principle of the Exclusives, "Separation from evil God's principle of unity," has led to many unimportant excommunications and separations besides those mentioned.

The theological views of the Brethren do not differ greatly from those held by evangelical Protestants (for a list of divergences, see Reid, *Plymouth Brethrenism Unveiled and Refuted*); they make the baptism of infants an open question and celebrate the Lord's Supper weekly. Their distinctive doctrines are ecclesiastical. They hold that all official ministry, anything like a clergy, whether on Episcopalian, Presbyterian, or Congregationalist theories, is a denial of the spiritual priesthood of all believers, and a striving against the Holy Spirit. Hence it is a point of conscience to have no communion with any church which possesses a regular ministry. The gradual growth of this opinion, and perhaps the reasons for holding it, may be traced in Mr. Darby's earlier writings. While a curate in the Church of Ireland he was indignant with Archbishop Magee¹ for stopping the progress of mission work among Roman Catholics by imposing on all who joined the church the oath of supremacy. This led Darby to the idea that established churches are as foreign to the spirit of Christianity as the papacy is ("Considerations addressed to the Archbishop of Dublin, etc." *Coll. Works*, vol. i. 1). The parochial system, when enforced to the extent of prohibiting the preaching of the gospel within a parish where the incumbent was opposed to it, led him to consider the whole system a hindrance to the proper work of the church and therefore anti-Christian ("Thoughts on the present position of the Home Mission," *Coll. Works*, i. 78). And the waste of power implied in the refusal to sanction lay-preaching seemed to him to lead to the conclusion that an official ministry was a refusal of the gifts of the Spirit to the church ("On Lay Preaching," *Coll. Works*, p. 200). These three ideas seem to have led in the end to Plymouthism; and the movement, if it has had small results in the formation of a sect, has at least set churches to consider how they might make their machinery more elastic. Perhaps one of the reasons of the comparatively small number of Brethren may be found in their idea that their mission is

¹ (William (1766-1831), two years bishop of Raphoe, and ten archbishop of Dublin. His grandson, William Connor Magee (1821-91), was twenty-two years bishop of Peterborough, and four months archbishop of York, England, an eloquent orator.—AM. ED.]

not to the heathen but to "the awakened in the churches."

PNEUMATIC DISPATCH. The transport of written dispatches through long narrow tubes by the agency of air-pressure was introduced in 1853, by Mr. Latimer Clark, between the Central and Stock Exchange stations of the Electric and International Telegraph Company in London. The stations were connected by a tube $1\frac{1}{2}$ inches in diameter and 220 yards long. Carriers containing batches of telegrams, and fitting piston-wise in the tube, were sucked through it (in one direction only) by the production of a partial vacuum at one end. In 1858 Mr. C. F. Varley improved the system by using compressed air to force the carriers in one direction, a partial vacuum being still used to draw them in the other direction. This improvement enables single radiating lines of pipe to be used both for sending and for receiving telegrams between a central station supplied with pumping machinery and outlying stations not so supplied. In the hands of Messrs. Culley and Sabine this radial system of pneumatic dispatch has been brought to great perfection in connection with the telegraphic department of the British post-office. Another method of working, extensively used in Paris and other Continental cities, is the circuit system, in which stations are grouped on circular or loop lines, round which carriers travel in one direction only. In one form of circuit system—that of Messrs. Siemens—a continuous current of air is kept up in the tube, and rocking switches are provided by which carriers can be quickly introduced or removed at any one of the stations on the line without interfering with the movement of other carriers in other parts of the circuit. More usually, however, the circuit system is worked by dispatching carriers, or trains of carriers, at relatively long intervals, the pressure or vacuum which gives motive power being applied only while such trains are on the line. On long circuits means are provided at several stations for putting on pressure or vacuum, so that the action may be limited to that section of the line on which the carriers are travelling at any time.

The following particulars refer to the radial system of pneumatic dispatch as used in the British post office. In London most of the lines connect the central office with district offices for the purpose of collecting and distributing telegrams. Iron tubes were used in some of the earliest lines, but now the tubes are always made of lead, with soldered joints, and are enclosed in outer pipes of iron for the sake of mechanical protection. The bore, which is very smooth and uniform, is normally $2\frac{1}{2}$ inches, though in a few cases it is as much as 3 inches, and in some only $1\frac{1}{2}$ inches. The greatest single length of any of the existing London lines is 3873 yards, but a more usual length is from 1000 to 2000 yards. In most cases a single tube serves both to send and to receive, but where the traffic is heavy a pair of tubes are used, one to send by pressure and the other to receive by vacuum. The pumps, which supply pressure and vacuum to two mains, are situated in the central office. At the outlying stations the tubes terminate in a glass box, open to the atmosphere. At the central station the end of each tube is a short vertical length, facing downwards, and provided with a double valve, consisting of two sluices, one at the end and the other a little way above the end, the distance between the sluices being somewhat longer than the length of a carrier. The sluices are geared together in such a manner that a single movement of a handle closes one and opens the other, or *vice versa*. To send a carrier from the central station, the carrier is introduced into the tube, the lower sluice being open; a single movement of the handle then successively (1) closes the lower sluice, (2) opens the upper sluice, and (3) opens a valve which admits air behind the carrier from the compressed-air main. As soon as the arrival of the carrier is signalled (electrically) from the out-station, the handle is pushed back, thus (1) cutting off

the compressed air, (2) closing the upper sluice, and (3) opening the lower sluice. The tube is then ready for the sending of another carrier. When an electric signal arrives from an out-station that a carrier is inserted there for transmission to the central station the handle is pulled forward far enough to close the lower and open the upper sluice, but not far enough to put on the air-pressure. The vacuum main is then put in connection with the tube by a separate stop-cock. When the carrier arrives the vacuum is shut off and the lower sluice opened to allow it to drop out. This arrangement of double sluices admits of the insertion or removal of a carrier while other carriers are travelling in the same tube, and without sensible disturbance of their motion. But great caution requires to be exercised in allowing two or more carriers to follow one another on a single section of line, especially on lines worked by pressure, since no two carriers travel at precisely the same speed. When the same tube is used alternately for sending and receiving the upper sluice is dispensed with. On some lines there are intermediate stations, and the sections are then worked by a block system like that used on railways. The carriers are cylindrical cases of gutta-percha covered with felt, which is allowed to project loosely at the back, so that the pressure makes it expand and fit the pipe closely. In front the carrier is closed by a buffer or piston composed of disks of felt of the diameter of the pipe. The dispatches are held in by an elastic band at the back. An ordinary carrier weighs $2\frac{1}{2}$ oz., and holds about a dozen dispatches. During business hours carriers are passing through the London tubes almost incessantly. With a pressure of 10 lb per square inch, or a vacuum of 7 lb, the time of transit, if through a $2\frac{1}{2}$ inch tube, is 1 minute for a length of nearly 1000 yards, and $5\frac{1}{2}$ minutes for a length of 3000 yards.

The following statistics show the growth of the pneumatic dispatch in the post-office during ten years (the figures for 1875 are taken from a paper by Messrs. Culley and Sabine, cited below, and those for 1885 have been furnished by Mr. W. H. Preece):

In Paris large areas of the city have been covered by pneumatic circuits made up of iron pipes round which omnibus trains of carriers are sent at intervals of fifteen minutes. The trains consist of several carriers much heavier than the English type, linked to one another and to a leading piston. The trains are stopped at the successive stations to take up and deposit dispatches. The pneumatic despatch took root in Paris in 1866, and has been developed there in a way which differs greatly in mechanical details from the English system. An arrangement like that used in Paris has been followed in Vienna and in Berlin, where the Siemens system has also been used. In New York the English system is adopted, but with brass instead of lead tubes.

Interruptions occurring in the pipes can be localized by firing a pistol at one end and registering by a chronograph the interval of time between the explosion and the arrival of the air-wave reflected from the obstacle.

In addition to its use for postal and telegraphic purposes the pneumatic despatch is occasionally employed for internal communication in offices, hotels, etc., and also in shops for the transport of money and bills between the cashier's desk and the counters.

References.—The system as now used in the United Kingdom is fully described in a paper by Messrs. Culley and Sabine (*Min. Proc. Inst. Civ. Eng.*, vol. xliii.). The same volume contains a description of the pneumatic telegraphs of Paris and of experiments on them by M. Bontemps, and also a discussion of the theory of pneumatic transmission by Prof. W. C. Unwin. Reference should also be made to a paper by C. Siemens (*Min. Proc. Inst. Civ. Eng.*, vol. xxxiii.) describing the Siemens circuit system; and to *Les Télégraphes*, by M. A. L. Ternant (Paris, 1881).

¹ Including 29 short "house" tubes.

PNEUMATICS is that department of hydrodynamics which treats of the properties of gases as distinct from liquids. Under HYDROMECHANICS will be found a general discussion of the subject as a branch of mathematical physics; here we shall limit our attention mainly to the experimental aspect.

The gaseous fluid with which we have chiefly to do is our atmosphere. Though practically invisible, it appeals in its properties to other of our senses, so that the evidences of its presence are manifold. Thus we feel it in its motion as wind, and observe the dynamical effects of this motion in the quiver of the leaf or the momentum of the frigate under weigh. It offers resistance to the passage of bodies through it, destroying their motion and transforming their energy—as is betrayed to our hearing in the whiz of the rifle bullet, to our sight in the flash of the meteor. In its general physical properties air has much in common with other gases. It is advisable therefore first to establish these general properties, and then consider the characteristic features of the several gases.

Matter is conveniently studied under the two great divisions of solids and fluids. The practically obvious distinction between these may be stated in dynamical language thus: solids can sustain a longitudinal pressure without being supported by a lateral pressure; fluids cannot. Hence any region of space enclosed by a rigid boundary can be easily filled with a fluid, which then takes the form of the bounding surface at every point of it. But here we distinguish between fluids according as they are gases or liquids. The gas will always completely fill the region, however small the quantity put in. Remove any portion and the remainder will expand so as to fill the whole space again. On the other hand it requires a definite quantity of liquid to fill the region. Remove any portion and a part of the space will be left unoccupied by liquid. Part of the liquid surface is then otherwise conditioned than by the form of the wall or bounding surface of the region; and if the portion of the wall not in contact with the liquid is removed the form and quantity of the liquid are in no way affected. Hence a liquid can be kept in an open vessel; a gas cannot so be.

The mutual action between any two portions of matter is called the stress between them. This stress has two aspects, according as its effect or tendency is considered with reference to the one or the other body. Thus between the earth and moon there is a stress which is an attraction. The one aspect is the force which attracts the moon to the earth; the other is the force which attracts the earth to the moon. According to Newton's third law of motion these are equal and opposite. Similarly the repulsive stress between the like poles of two magnets has its two aspects, which are equal but oppositely directed forces. In the case of a mass hanging by a cord, the stress is a tension at every point of the cord. At any given point this tension has two equal and opposite aspects, one of which is the weight of the mass and the portion of the cord below the given point. Finally, the stress between any body and the horizontal table on which it rests is a two-faced pressure, being downwards as regards the table, upwards as regards the body. The total pressure upon the table over the whole surface of contact is clearly the weight of the body. If the total pressure is supposed to be uniformly distributed, the measure of the pressure on unit surface is the quotient of this weight by the area of the surface. When we speak of pressure at a point, it is this pressure on unit surface that is meant. When the pressure varies from point to point over a surface, the pressure at any point is defined to be the limit of the ratio of the total pressure over any small element of surface around that point to the area of the element as the element is diminished indefinitely.

The stress which exists between the contiguous portions of a fluid is of the nature of a pressure. The ideal or perfect fluid is a substance in which this stress between contiguous portions is always perpendicular to the common interface. In other words there is no stress tangential to the interface at any point. Hence if the contiguous portions are at relative rest, or have a relative motion parallel to the interface, neither state can be affected by the mutual stress. This condition is perfectly fulfilled in the case of any known fluid in equilibrium; but for a fluid in motion it is not even approximately fulfilled. For, any visible relative motion set up among the parts of a fluid rapidly decays in virtue of viscosity, which even for the subtlest gases is quite appreciable in its effects.

In a fluid at rest, then, the pressure over any surface which we may imagine to be drawn is perpendicular (or normal) to the surface at every point of it; and from this it follows at once, as has been proved in HYDROMECHANICS, vol. xii. p. 455, that the pressure at any point of a fluid at rest has the same value in all possible directions.

The pressure at two contiguous points in a fluid may either differ or not. If they differ, the change of pressure must be balanced by some extraneous force acting on the fluid in the direction in which the pressure increases. Any direction in which no such force acts must be a direction in which there is no change of pressure; otherwise, equilibrium will be destroyed. Suppose now the resultant force at every point in a fluid at rest to be given. In directions at right angles to the force at any given point the pressure will not vary. Hence we can pass to an infinite number of contiguous points at which the pressure is the same as at the given point. By making each of these in turn the starting-point, we can pass on to another set of points, and so gradually trace out within the fluid a surface at every point of which the pressure is the same. Such a surface is called a surface of equal pressure, or briefly a level surface; and we see from the mode of its construction that it is at every point of it perpendicular to the resultant force at that point.

Imagine any two contiguous level surfaces to be drawn, at every point of the one of which the pressure is p , at every point of the other $p + \delta p$. Consider the equilibrium of a small column of average density ρ , bounded at its ends by these surfaces. Let A be the area of each end, and δr the length of the column or perpendicular distance between the level surfaces. If R is the average resultant force per unit mass acting on the column, then we have, for equilibrium of the column,

$$A\delta p = A\delta r \cdot \rho R,$$

or

$$\delta p = R\rho\delta r.$$

or the rate of increase of the pressure at any point per unit of length at right angles to the level surface is equal to the resultant force per unit of volume at that point.

If the applied forces belong to a conservative system, for which V is the potential (see MECHANICS), we may write the equation in the form

$$\delta p = -\rho\delta V.$$

Hence over an equipotential surface, for which $\delta V = 0$, p is constant, and is therefore a function of V . Consequently ρ also is a function of V . For a fluid in equilibrium, therefore, and under the influence of a conservative system of forces, the pressure and density are constant over every equipotential surface, that is, over every surface cutting the lines of force at right angles.

Now in the case of gases, to which our attention is at present confined, the density (temperature remaining constant) varies with every change of pressure; in mathematical language ρ is a function of p . Thus, before we can solve the equation of equilibrium for a gas, we must be able to express this function mathe-

Equipotential surfaces.

matically; in other words, we must know the exact relation between the density of a gas and the pressure to which it is subject. This problem, which can only be settled by experiment, was solved for the case of air within a certain range of pressures by Robert Boyle (1662). Before discussing his results and the later results of other investigators, we shall first consider the general properties of our atmosphere as recognized before Boyle's day.

It is evident that, for a fluid situated as our atmosphere is, the pressure must diminish as we ascend. The equipotential surfaces and consequently the surfaces of equal pressure and of equal density will be approximately spheres concentric with the earth. At any point there will be a definite atmospheric pressure, which is equal numerically to the weight of the superincumbent vertical column of air of unit cross-section. The effect of this pressure, as exemplified in the action of the common suction-pump, seems to have been first truly recognized by Galileo, who showed that the maximum depth from which water can be pumped is equal to the height of the water column which would exert at its base a pressure equal to the atmospheric pressure. As an experimental verification, he suggested filling with water a long pipe closed at the upper end, and immersing it with its lower and open end in a reservoir of the same liquid. The liquid surface in the pipe would, if the pipe were long enough, stand at a definite height, which would be the same for all longer lengths of pipe. The practical difficulty of constructing a long enough tube (33 feet at least) prevented the experiment being really made till many years later.

Torricelli, however, in 1642, by substituting mercury for water, produced the experiment on a manageable scale. As mercury is denser than water in the ratio of about 13.6:1, the mercury column necessary to balance by its weight the atmospheric pressure will be less than the water column in the inverse ratio, or a little under 30 inches. Torricelli's experiment is exhibited in every mercurial barometer (see BAROMETER and METEOROLOGY). By this experiment he not only gave the complete experimental verification of Galileo's views relating to atmospheric pressure, but provided a ready means of measuring that pressure.

The most obvious applications of the barometer are these: (1) to measure the variation in time of atmospheric pressure at any one locality on the earth's surface (the existence of this variation was discovered soon after the date of Torricelli's experiment by Pascal, Descartes, Boyle, and others); (2) to measure the variation of atmospheric pressure with change of height above the earth's surface (Descartes mentions this application in the *Principia Philosophiæ*, 1644; but to Pascal is the honor due of having first carried the experiment into execution, 1647); and (3) to compare pressures at different localities which are on the same level (if the pressures are equal, the air is in equilibrium; if they are not, there must be flow of air from the place of higher pressure to that of lower—in other words, there must be wind, whose direction of motion depends on the relative position of the places, and whose intensity depends on the distance between the places and the difference of pressures). The first and last of these measurements are of the greatest importance in meteorology. The second is a valuable method for measuring attainable heights, and is intimately connected with the problem as to the relation between the pressure and density of the air. Thus it would be possible, by barometric observations at a series of points in the same vertical line, to obtain a knowledge of this relation—more and more truly approximate the closer and more numerous the points of observation taken. At best, however, such a method could give the law connecting density with pressure, for those pressures only which are less than the normal atmospheric pressure. The problem is better solved otherwise.

Assuming Boyle's law that the density of air is directly as the pressure, we can now integrate the equation of equilibrium

$$\rho p = -\rho \delta V,$$

and put it in the form

$$p = p_0 e^{-V/K},$$

where p_0 is the pressure at zero potential and K is the constant ratio of the pressure to the density.

For all attainable heights in our atmosphere we may assume the force of gravity to be the same. Hence we may write $V = gh$, where g is the force acting on unit mass at height h . If we put $K = gH$, the equation becomes

$$p = p_0 e^{-h/H},$$

where H is obviously the height of a fluid of uniform density p_0/K which would give at its base the pressure p_0 —in other words, the height of the homogeneous atmosphere, as it is called. Its value is readily found, since it bears to the height of the mercurial barometric column the same ratio which the density of mercury bears to the density of the atmosphere at the sea-level. For dry air at 0°C . and with g taken as equal to 981 dynes ($= 32.2$ poundals nearly), the value of H is 7.9887×10^5 centimetres, or 26,210 feet. Hence the formula giving the height above the sea-level in terms of the pressure may be written

$$h = 7.9887 \times 10^5 \times \text{Nap. log. } (p_0/p)$$

In practice this formula must be modified to suit regions where g is other than 981, and where the temperature is other than 0° . The effect of the water-vapor present must also be taken into account, and the constants involved carefully tested by observation. The subject is treated in detail under BAROMETER.

In an appendix to the *New Experiments, Physico-Mechanical, etc., touching the Spring of Air* (1660), Robert Boyle states that the density of air is directly as the

pressure. His apparatus and method of experiment are as follows. A U-shaped tube is taken, one of whose limbs is considerably longer than the other. The shorter limb is closed at the end; and the whole apparatus is set vertically with the open end pointing upwards. A small quantity of mercury fills the bend, so that at the beginning of the experiment the two mercury surfaces are at the same level. Hence the air confined in the shorter limb is subjected to a pressure along its lower surface equal to the atmospheric pressure, or one atmosphere as it is commonly called. As the height of the air column in the closed tube is small, the pressure and density are practically the same throughout. Now let mercury be poured into the longer limb. The free mercury surface will be observed to rise in the shorter limb, so that the air confined there becomes compressed into smaller bulk. Since the mass of air has not altered, the density is obviously inversely as the bulk, and can therefore be easily measured. Again, the pressure to which the confined air is now subjected is equal to the pressure over that surface in the mercury in the open limb which is at the same level as the free mercury surface in the closed limb. But this pressure is clearly the sum of the atmospheric pressure and the pressure due to the superincumbent column of mercury, which latter can be readily expressed in atmospheres if the height of the barometer is known. In other words, divide the vertical distance between the two mercury surfaces by the height of the barometer column. The quotient added to unity gives the required pressure in atmospheres.

Fourteen years after the date of the publication of Boyle's results, Mariotte,¹ working independently, discovered the same law, which is still widely known on the Continent as Mariotte's law. He supplemented Boyle's experiments by investigating the effect of pressures less than that of the atmosphere, and proved that the same law held at these diminished pressures. His method was essentially as follows. A barometer tube is filled in the ordinary way with mercury and fixed up as in the

Relation between height and pressure in our atmosphere.

Boyle's experiment.

Mariotte's experiments.

¹ *Traité de la Nature de l'Air*, 1676.

Torricellian experiment. A little air is then introduced at the lower end of the tube which is dipping in the reservoir of mercury. This air travels up the tube and fills the Torricellian vacuum at the top, thereby depressing to a slight extent the barometer column. The amount of depression divided by the true height of the barometer gives the pressure in atmospheres which acts upon the air in the tube. The tube, always kept truly vertical, dips in a reservoir of mercury sufficiently deep to admit of its complete immersion. For a certain position of the tube the free surfaces of mercury in the tube and reservoir are at the same level. For that position the confined air is at the atmospheric pressure; and for any higher position of the tube the pressure in the confined mass of air is less than the atmospheric pressure by the pressure due to the column of mercury between the free surfaces. Recent

experiments by Kraevitch and Petersen (*Journal of the Russian Chemical Society*, vol. xvi.) seem to show that very rarefied air is very far from obeying Boyle's law. At such low pressure, the condensation of the gas upon solid surfaces is an important factor.

For most ordinary purposes Boyle's law—that, at constant temperature, the density of a gas varies directly as the pressure—may be assumed to be true, at least for moderate ranges of pressure; but the careful investigations of later experimenters, such as Oersted, Despretz, Dulong, Regnault, Andrews, Cailletet, and Amagat, have proved that the law is only approximate for every known gas, and that the deviation from correspondence with the law is different for each gas. The most recent investigations are those of Cailletet and Amagat, who have carried the results to much higher pressures than former experimenters employed. Both

adopted in the first place a form of apparatus essentially the same as Boyle's, only much longer. The gas was subjected to the pressure of a mercury column enclosed in a strong narrow steel tube; and, as oxygen acts vigorously upon mercury at high pressures, nitrogen was used. In this way Cailletet² attained to a pressure of 182 metres of mercury, and Amagat³ to a pressure of nearly 330.

Having thus determined accurately the correspond-

ing pressures and densities of nitrogen, Amagat proceeded to determine the relation for other gases by Pouillet's differential method. That is, the pressure to which the new gas was subjected was made to act simultaneously upon a given mass of nitrogen, whose volume could be readily measured and pressure estimated. Oxygen, hydrogen, carbonic oxide, dry air, olefiant gas, and marsh gas were investigated in this way. The general results obtained by Amagat are exhibited in the subjoined chart taken from his paper. For all gases except hydrogen the product pV (pressure into volume), instead of being constant, as Boyle's law would re-

¹ [The chart should read carbonic acid.—AM. ED.]

² *Journal de Physique*, vol. viii. 1879.

³ *Annales de Chimie et de Physique*, vol. xix., 1880.

quire, diminishes at first as the pressure is increased. At a certain pressure, however, different for each gas, the diminution ceases, and if the pressure is still further increased the product $p\bar{v}$ begins to increase also, and continues so to do to the greatest pressure used. In the case of hydrogen the product increases from the very beginning.

On the diagram, abscissæ represent pressures in metres of mercury, and the ordinates represent the deviations from the Boylean law. It will be observed that all the curves pass through the point on the pressure axis which represents a pressure of 24 metres of mercury. If π represents the product $p\bar{v}$ for any gas at this pressure, and π' the corresponding product for any other pressure, then we may write

$$\pi/\pi' = 1 + \delta,$$

where δ represents the deviation from Boyle's law. All the curves except that for hydrogen show a well-marked minimum, at and near the pressure corresponding to which the particular gas obeys Boyle's law. For the several gases these positions occur at the pressures as given in the following table:

Nitrogen.....	50 m.	Carbonic acid.....	50 m.
Oxygen.....	100 m.	Marsh gas.....	120 m.
Air.....	65 m.	Olefiant gas.....	65 m.

For olefiant gas δ is so great, and varies so rapidly, that only portions of the curve are represented. The value of δ for its minimum point is -1.3 , while the corresponding value for oxygen is -0.05 . In these experiments the temperature of the gases varied between 18° and 22° C.

Amagat¹ has extended his researches to higher temperatures up to 100° C. The general characters of the curves obtained for hydrogen, nitrogen, olefiant gas and marsh gas remain the same as at the ordinary temperature; that is, with the exception of hydrogen, the product $p\bar{v}$ decreases to a minimum and then increases indefinitely.

The position of the minimum changes with the temperature. Thus for olefiant gas and carbonic acid gas (whose properties were also studied at these higher temperatures), the pressure at which the minimum occurs increases with the temperature, while in the case of nitrogen and marsh gas this critical pressure decreases as the temperature rises. Probably at some temperature higher than 100° olefiant gas and carbonic acid gas would begin to behave like nitrogen, and all would appear to tend more and more, as the temperature rises, to the condition of which hydrogen is the type. That is, the deviation from the Boylean law up to the minimum point would steadily decrease until finally the curve would cease to have a marked minimum. For any one gas, the higher the temperature the less the curvature at the minimum point; and the comparison of different gases seems to indicate that the curvature is greater for the more easily liquefiable gas. At sufficiently high temperatures the law of compressibility for all gases approximates to the relation

$$P(V-a) = \text{constant},$$

where P is the pressure, V the volume, and a a constant. Hydrogen follows this law very closely at the ordinary temperature of the air, as the straightness of its representative curve shows at a glance.

Amagat has further discussed by means of his results the law of dilatation of gases. This law is named Charles's law, after the discoverer of it. Stated simply, it is that at constant pressure every gas expands by the same fraction of itself for a given rise from a given temperature. Charles did not publish his results; and it was not till fifteen years later, when Dalton and Gay-Lussac, working independently, rediscovered it, that the law became generally known. Their results were published in 1801² and 1802³ respectively; and it is upon the authority of the latter, who accidentally became acquainted with the fact, that the law is now named after Charles. The careful measurements of Magnus,⁴ Regnault,⁵ Jolly, and others have established that there is an appreciable difference in the coefficients of expansion for the different gases. The difference is slight for the so-called permanent gases—air, nitrogen, oxygen, hydrogen, and marsh gas; but for the more easily

liquefiable gases it is quite marked. The mean coefficient of expansion for air between 0° C. and 100° C. and at the ordinary atmospheric pressure is .003665 per degree, and the value for any one of the gases just mentioned does not certainly differ from this by one-half per cent.⁶ This may be expressed by the formula

$$v = KT,$$

where K is a constant and T the temperature measured from absolute zero, which is 274° C. below the freezing point of water (see HEAT). When T is constant, we have by Boyle's law the product $p\bar{v}$ also constant. Hence we may combine the two laws in the form

$$p\bar{v} = RT,$$

where R is a constant. We thus see that, Boyle's law being assumed to be true at all temperatures, Charles's law, if true for any given pressure, is true for every other pressure. Further, if v is kept constant the rate of increase of $\log p$ with temperature will be expressed by the same number as the rate of increase of $\log v$ when p is kept constant. Experiment has fully verified this conclusion to as close an approximation as Boyle's and Charles's laws themselves are fulfilled. The rate of increase of $\log v$ with temperature, or, what is the same thing, the ratio of the rate of increase of the volume to the original volume, is given by the formula

$$\frac{1}{v} \frac{dv}{dT} = \frac{1}{T};$$

and this is the measure of the coefficient of expansion at temperature T . Hence the coefficient of expansion diminishes as the temperature rises, a conclusion also in accordance with experiment so long as we are dealing with gases which nearly obey Boyle's and Charles's laws.

We have seen, however, that even in the case of hydrogen the departure from Boyle's law is very marked at the higher pressures; and therefore we cannot expect a closely numerical agreement between the results of experiment and the results of calculation from the above formula. Thus, it is not surprising that practically the coefficient of expansion should be affected by the pressure, as Amagat's experiments clearly show,—although in the equation deduced above the pressure does not enter. In the following table given by Amagat, the second column contains the mean coefficients of expansion of hydrogen between 17° and 60° C. at the pressures given in the first column; and the third column contains the corresponding mean coefficients between 60° and 100° C.

Pressure in Metres of Mercury.	17° – 60° .	60° – 100° .
40	.0033	.0029
100	.0033	.0028
180	.0031	.0027
260	.0030	.0025
320	.0028	.0024

The temperature effect upon the coefficient of expansion, as shown by these numbers, is approximately that indicated above, viz., that at constant pressure the coefficient of expansion is inversely as the absolute temperature. A glance down each column shows at once the marked effect of pressure. In this steady decrease of the coefficient of expansion with increase of pressure, hydrogen stands alone amongst the substances discussed by Amagat. His conclusions are given in these words:

1. The coefficient of expansion of gases increases with

⁶ The first who really gave accurate values of these quantities was Rudberg.

¹ *Annales de Chimie et de Physique*, vol. xxii., 1881.

⁴ *Pogg. Ann.*, lv., 1841.

⁵ *Mém. de l'Acad.*, xxi.

the pressure to a maximum, after which it decreases indefinitely.

2. This maximum occurs at the pressure for which at constant temperature the product $p v$ is a minimum, that is, the pressure at which the gas follows for the instant Boyle's law.

3. With increasing temperature this maximum becomes less and less sensible, finally disappearing with the minimum characteristic of the compressibility curve.

Thus, as hydrogen does not show this minimum characteristic, its coefficient of expansion has no maximum value. Possibly at lower temperatures hydrogen may, however, possess these characteristics.

It thus appears that the simple gaseous laws established by Boyle and Charles are most nearly fulfilled by those gases which are difficult to liquefy, and are better fulfilled by all the higher the temperature is. When a gas is near its point of liquefaction the density increases more rapidly than the pressure, or in other words the volume diminishes more quickly than Boyle's law requires. When the point of liquefaction is actually reached, the slightest increase of pressure condenses the whole of the gas into a liquid; and in this state the alteration of volume is very small even for a large increase of pressure.

The transition from the gaseous to the liquid state is conveniently studied by the help of isotherms. Isotherms. thermal lines, which may be generally defined as curves showing the relation between two mutually dependent variables for given constant temperatures. Such variables are the pressure and volume of a mass of gas. Let the numbers representing the volumes be measured from a chosen origin along a horizontal axis, and the numbers representing the pressures similarly along a vertical axis passing through the same origin. If we consider a mass of gas at a given temperature, for any volume that can be named there will be a definite pressure corresponding, and *vice versa*. Hence the point whose coördinates are the corresponding volume and pressure is completely determined if either coördinate is given. The temperature always being kept constant, let now the volume change continuously. The pressure will also alter according to a definite law; and the point whose coördinates are at any instant the corresponding volume and pressure will trace out a curve. This curve is an isothermal curve, or simply an *isotherm*. If Boyle's law were fulfilled, the equation to the isotherm for any given temperature would be of the form

$$p v = \text{constant.}$$

The isotherm would be a rectangular hyperbola, whose asymptotes are the coördinate axes. For any gas not near its point of liquefaction the isotherm will not deviate greatly from the hyperbolic form.

Let now the pressure be kept constant, and the gas raised somewhat in temperature. The volume of course increases, and the corresponding point on the diagram moves off the original isotherm. Through this point in its new position we can draw a second isotherm corresponding to the new temperature. And thus the whole field may be mapped out by a series of isotherms, each one of which corresponds to a definite temperature. The higher the temperature the farther does the isotherm lie from the origin. Such a mapped out diagram or chart shows at a glance the relations between the volume, pressure, and temperature of a given mass of gas, so that if any two of these are given the third can be found at once.

So long as the substance is in the gaseous form, the isotherm remains approximately hyperbolic; but at the pressure at which liquefaction takes place a marked change occurs in the form of the curve. For greater definiteness consider the case of a gramme of steam at 100° C. and at a pressure somewhat below one atmosphere. As the pressure is increased, the volume diminishes appreciably faster than Boyle's law re-

quires, but still in such a way as to give an approximately hyperbolic form to the isotherm. When the pressure reaches one atmosphere, however, any further increase is accompanied by the liquefaction of the whole; that is, the volume suddenly diminishes from 1647.5 cubic centimetres to 1 cubic centimetre. Between these extremes of volume, the isotherm is a straight line parallel to the horizontal axis. The pressure remains constant until the whole of the gas is liquefied. In other words, *the pressure of a gas in presence of its liquid does not alter provided the temperature is kept constant*. This is a partial statement of the more general law that the temperature of the liquid surface alone determines the maximum pressure which its vapor or gas in contact therewith can exert (see HEAT). After the whole has been liquefied, any increase of pressure is accompanied by a very minute diminution of volume. Hence the isotherm rises abruptly from the point whose coördinates are 1 cubic centimetre and 1 atmosphere, becoming nearly but not quite vertical. Thus, the isotherm for water-substance at 100° consists of three parts: an approximately hyperbolic portion for pressures less than one atmosphere, the substance being then wholly gaseous; a horizontal portion, corresponding to the state in which the substance is partly liquid partly gaseous; and a nearly vertical portion for pressures higher than one atmosphere, the substance being then wholly liquid. If we trace out the isotherm for some higher temperature, say 150° C., we obtain the same general characteristics. The straight line portion, however, is not so long, for two reasons: the steam must be reduced to a smaller volume before liquefaction begins; and the volume of the liquid when condensed is greater. The pressure corresponding to the transition state is in this case 4.7 atmospheres, and the range of volumes is from 384.4 cubic centimetres in the gaseous state to 1.038 cubic centimetres in the liquid state. It thus appears that the positions of the two points of abrupt change on an isotherm draw nearer the higher the temperature, coming together finally when the temperature has reached a certain critical value. In other words, at and above a certain temperature a liquid and its vapor cannot co-exist. This temperature for water-substance is very high, somewhere about the point of fusion of zinc, and is therefore difficult to measure.

Dr. Andrews's, however, in his classical researches on carbonic acid gas,¹ to which we owe most of what is said above, has discussed the whole subject in a very complete manner. This substance, at a temperature of 13.1° C., begins to liquefy at a pressure of 47 atmospheres. During the process of liquefaction there is a perfectly visible liquid surface separating the two coexisting states of the substance; and the isotherm has a corresponding straight line portion. At a temperature of 21.5° C. liquefaction occurs at a pressure of 60 atmospheres. The horizontal portion of the isotherm, which marks the co-existence of the gaseous and liquid states, is considerably shorter than at the former temperature. The isotherm for 31.1° C., however, has no such rectilinear characteristic; and at this and higher temperatures the substance is never during the whole compression in two distinct conditions at once. It is impossible to say when the dense gaseous condition passes into the light liquid condition. The two states are absolutely continuous. The critical temperature—that is, the temperature below which there is a distinct separation between the liquid and the gas—is fixed by Dr. Andrews at 30.92° C. for carbonic acid gas. Above this temperature it is impossible to obtain a free liquid surface in a closed vessel. This conclusion had already been arrived at by Faraday in 1826, when he considered himself entitled to state that above a certain temperature no amount of pressure will produce the phenomenon known as condensation.

Andrews's results also give the true explanation of the observations made by Cagniard-Latour¹ in 1822 upon the effect of high temperature on liquids enclosed in glass tubes which they nearly filled. He found that at a certain temperature the free liquid surface disappeared, and the tube became filled with a substance of perfectly uniform appearance throughout. He concluded that the whole had become gaseous. In reality he had reached the critical temperature at which the liquid and gaseous conditions pass continuously the one into the other. The following are Cagniard-Latour's estimated values for the temperature and pressure of various substances at the critical point :

	Temperature.	Pressure.
Ether.....	175° C.	38 atmospheres.
Alcohol.....	248° "	119 "
Bisulphide of carbon...	258° "	71 "

Avenarius² and Drion³ have studied the critical temperature of other substances, such as sulphuric acid, acetone, and carbon tetrachloride. The substances, however, which can be so studied are comparatively few, since the greater number of those which are liquid under ordinary conditions have their critical temperatures very high, while the majority of those which are gaseous have theirs very low.

The necessity for a very low temperature long prevented the obtaining in a liquid form of the standard gases—hydrogen, oxygen, nitrogen, etc.—which were accordingly distinguished by the name *permanent gases*. Faraday⁴ proved that these could not be liquefied at a temperature of —110° C., even when subjected to a pressure of 27 atmospheres. Natterer⁵ likewise failed to reduce these gases to the liquid state, even at a pressure of 3000 atmospheres. His means for reducing the temperature were not satisfactory. In 1877 Cailletet and Pictet, working independently, first successfully effected their approximate liquefaction. The former compressed each of the gases oxygen, nitrogen, and carbonic oxide to 300 atmospheres in a glass tube, which was cooled to —29° C.⁶ When the gas was allowed to escape, it did so in the form of a cloud, condensing for the moment to the liquid state under the influence of the extreme cold produced by the rapid expansion of the gas. Pictet in a similar way obtained an issuing stream of liquid oxygen. Von Wroblewski and Olzewski⁷ have more recently obtained oxygen, nitrogen, and carbonic oxide in a more evident liquid state. They used Cailletet's form of apparatus, and cooled the gas by means of the evaporation of liquid ethylene. Under this extreme cold they observed these substances forming a well-defined liquid in the bottom of the tube. The following table gives the results of five different observations at slightly different temperatures.

Temp., C...	—129.6°	—131.6°	—133.4°	—134.8°	—135.8°
Pressure, in atmos.....	27.02	25.85	24.4	23.18	22.2

At slightly higher temperatures, the pressure necessary for the liquefaction increased very rapidly. Nitrogen and carbonic oxide were not so easily reduced, remaining still gaseous at —136° C., and under

a pressure of 150 atmospheres. By a sudden diminution of the pressure to 50 atmospheres there was obtained under the influence of the reduced temperature a rapidly evaporating liquid. The critical point of oxygen has been experimentally fixed by Von Wroblewski⁸ at —113° C. and 50 atmospheres pressure. With the data given by Amagat's researches, Sarrau⁹ has calculated from a formula of Clausius's the following values of the critical temperature and pressure for oxygen, nitrogen, hydrogen :

	Critical Temperature.	Critical Pressure.
Oxygen.....	—105.4° C.	48.7 atmospheres.
Nitrogen.....	—123.8°	42.1 "
Hydrogen.....	—174.2°	98.9 "

It will be observed that Von Wroblewski's observed values for oxygen are in remarkably close agreement with the calculated values given here. Apparently oxygen is just at the limit fixed by Faraday.

The behavior of a gas under varying pressure is a phenomenon of great practical importance, Manometer, and gives a valuable method for measuring pressures (see MANOMETER).

A modification of the ordinary mercury manometer is used for measuring volumes, and is especially valuable in estimating the densities of substances which cannot be put into water, such for example as liquids or powders. The closed end of the manometer tube, which by means of a stop-cock may be opened to the air at will, is fitted to a flask with which it may be put into connection when required. Two fiducial marks are then made upon it—one at the position where the mercury surfaces in the two limbs of the tube are co-level, and the other somewhat higher at a convenient spot. Between the two marks the tube expands into a bulb, thereby increasing the intervening volume and minimizing the effect of any slight error in bringing the mercury surface to the higher mark. Let the volume of the flask and tube down to the higher mark be v , and the volume of the rest of the tube down to the lower mark V . At first the volume of air in the flask and tube is $V+v$, at the atmospheric pressure P . Now pour mercury into the open end till the liquid surface in the closed end reaches the higher mark. The air has been compressed to volume v ; and the corresponding pressure, as measured by the balanced mercury column, is $p+P$. Hence

$$(p+P)v = P(V+v).$$

Let now a volume x be placed in the flask, and let the same succession of operations be made. Then, if p' be the increase of pressure necessary to bring the mercury surface from the lower to the higher fiducial mark, we have

$$(p'+P)(v-x) = P(V+v-x).$$

As V can be readily determined by gauging the tube, and as P , p , p' are all known, the quantities v and x can be at once found from these equations.

In many experiments on the properties of gases it is necessary to have an efficient and rapid means for altering the density. Instruments for this purpose are called air-pumps, and their function may be either to rarefy or condense the air—usually the former.

Otto Von Guericke of Magdeburg constructed the first air pump about the year 1652. It was simply a spherical glass vessel opening below by means of a stop-cock and narrow nozzle into the cylinder of an "exhausting syringe," which inclined upwards from the extremity of the nozzle. The cylinder, in which a well-fitting piston worked, was provided at its lower end with two valves. One of these opened from the nozzle into the

cylinder, the other from the cylinder into the outside air. During the down-stroke of the piston the former was pressed home, so that no air entered the nozzle and vessel, while the latter was forced open by the air which so escaped from the cylinder. During the return stroke the latter was kept closed in virtue of the partial vacuum formed within the cylinder, while at the same time the former was forced open by the pressure of the denser air in the vessel and nozzle. Thus, at every complete stroke of the piston, the air in the vessel or receiver was diminished (nearly) by that fraction of itself which is expressed by the ratio of the volume of the available cylindrical space above the outward opening valve to the whole volume of receiver, nozzle, and cylinder.

Boyle, on hearing of Von Guericke's success in applying the expansive properties of air as a means to its rarefaction, constructed a machine essentially the same as Von Guericke's, of which no description had then been published. Boyle, however, made the exhausting cylinder a continuation of the nozzle, which was thus considerably reduced in size, and worked the piston by means of a wheel and ratchet work. He also employed a transparent glass receiver with removable cover, so that the operator could observe what was going on inside, and more easily alter the contents. Other modifications and improvements followed rapidly; and in the carrying out of these Boyle was greatly aided by Hooke, who conceived the happy idea of using two syringes opening into the same duct from the receiver. This improvement has recently been credited to Papin.¹ In this form the pistons are worked by the same toothed wheel, and are so adjusted that the one rises as the other falls. This arrangement not only doubles the rate of exhaustion per stroke, but vastly increases the ease of working. In the single-barrelled form the piston is drawn back against a pressure of air which is greater the more complete the exhaustion is within; but in the double-barrelled form the downward pressures upon the two pistons to a certain extent counteract each other, producing opposite rotational effects on the toothed wheel and driving handle. Boyle also early adopted the flat plate, on which could be set receivers of various shapes and sizes. The junction of the plate and receiver he made tolerably air-tight by covering the plate with wet leather and having the receiver rim ground flat. According to Gerland, the invention of the plate is due to Huygens, who constructed the first air-pump so provided in 1661, shortly after a visit to London, where his interest in the subject was awakened by Boyle. To Huygens, probably in conjunction with Papin, is also due the application of the mercury manometer to measure the pressure in the receiver—an indispensable equipment in all serviceable air-pumps. The form of the piston plugs and valves received the special attention of Papin, who by his refined and detailed improvements did much to increase the efficiency of the apparatus.

The important characteristics of an efficient air-pump are as follows. The piston must work smoothly and easily. The valves must act precisely, and be when closed absolutely air-tight. The plate on which the receivers rest must be smooth and plane, so that the ground edges of the receivers may be in close contact all round. This perfect fitting is beyond the powers of the best workmanship, so that it is necessary to press between the receiver and plate a thin layer of lard, which renders the junction air-tight. Somewhere in the duct leading from the receiver to the piston cylinders, a stop-cock must be fixed, so that it may be possible to shut off the receiver completely from these. Then a second stop-cock is required as a ready means for admitting air to the receiver, whenever the need should arise. A combination three-way stop-cock is a

very usual form. And, finally, the apparatus should be provided with a pressure gauge—a mercury manometer communicating by means of a duct with the main duct and receiver.

The double-barrelled form of reciprocating air-pump, as finally employed by Boyle, is still much in use; but it is gradually being superseded by Bianchi's, which has but one cylinder and piston. The piston is, however, double-acting, as the cylinder communicates both above and below by suitable valves with the main duct which leads to the receiver. Hence, during both the up and down strokes of the piston, exhaustion is being effected, the gas which is in the *diminishing* chamber being driven out through a suitable valve to the open air. The chief merit of Bianchi's machine, however, as compared with the older form, lies in the mechanism by which the piston is driven. The end of the piston rod is attached by a crank to a rotating horizontal axle, which is in gearing with the axle of a fly-wheel. The piston cylinder is capable of a reciprocating oscillatory motion about its lower end, which pivots on a horizontal axis. Thus, as the crank rotates, the piston rises and falls in the cylinder, and oscillates along with it from side to side. The driving power is applied to a handle fixed to the fly-wheel. This substitution of a continuous rotatory motion for a reciprocating motion greatly facilitates rapid exhaustion.

At every complete stroke of the piston the pressure of air in the receiver is reduced by a definite fraction of itself, which depends upon the relative volumes of the receiver and piston cylinder. Hence the absolute change of pressure per stroke is smaller as the pressure is smaller; and the rate of exhaustion at very low pressures becomes practically inappreciable. There is, in fact, a practical limit to exhaustion, the particular value of which depends upon the special characteristics of the instrument. The best air-pumps of the type described above cannot reduce the pressure to less than what would balance one or two millimetres of mercury—that is, to what is technically called a pressure of one or two millimetres. To obtain a lower pressure or a *higher vacuum*, as it is commonly termed, requires the use of a different principle.

In a well-constructed barometer the region above the mercury contains no air. It is not an absolute vacuum, but is filled with vapor of mercury at a very low pressure—according to Regnault, .0372 mm. at 20° C., and .02 mm. at 0° C. The way in which the Torricellian vacuum has been applied to give a practical air-pump has been described in MERCURIAL AIR-PUMP. So long as mercury vapor is permitted to pass freely through the exhausting tubes, it is impossible to obtain by the mercurial air-pump pressures lower than the fortieth of a millimetre. If, however, there is placed somewhere in the duct leading from the mercury pump to the receiver, a non-volatile substance which absorbs mercury vapor, the mercury vapor will be arrested. With similar precautions for the absorption of water vapor or other vapor which may be present, it is possible to obtain very low pressures indeed. Thus Crookes² in his radiometer experiments obtained pressures as low as .00015 mm. or the .2 millionth of an atmosphere. The form of pump used was of Geissler's type. The water vapor was absorbed by phosphoric anhydride. Sulphur was used to absorb the mercury vapor; and on the further side metallic copper was placed to absorb any sulphur vapor which might tend to pass.

The best test of a good vacuum is the electrical test. Disruptive discharge through a long tube filled with gas is possible only when the gas is very rare, but there is a point in the rarefaction of a gas at which the discharge passes most easily. In other words, the dielectric strength of a gas reaches a

minimum as its pressure is diminished, and it is possible to obtain such a high vacuum that electric discharge will not take place through any considerable length of the exhausted space (see *ELECTRICITY*). In this connection we may notice a simple but instructive experiment of Dewar's. He carefully exhausted a vacuum tube, in which he had previously inserted a piece of carbon. In the last stages of the exhaustion the carbon was strongly heated so as to drive off most of the gas which is always condensed on its surface. After the completion of the exhaustion, the tube was sealed up and the carbon allowed to cool. As it cooled, it condensed over its surface the greater portion of the small quantity of gas left in the vacuum tube. The vacuum was thus vastly improved, so that it was impossible to pass an electric spark between two platinum electrodes which had been previously fused into the glass. A gentle heat applied to the carbon, however, was sufficient to drive off from its surface enough of the occluded gas to raise the pressure to the point necessary for the passage of the electricity. As the carbon cooled again, the high vacuum was restored and the discharge ceased.

It is hardly necessary to do more than mention the other class of air-pumps. Let the essential valves in an exhausting pump have their actions reversed, and the apparatus will become a condensing pump. The condensing syringe is the usual form of such a pump; but, compared to the exhausting instrument, it has very limited applications. For the mere obtaining of high pressures hydraulic means are preferable, being at once more manageable and less dangerous. Besides, even moderately slow compression of a gas is accompanied by considerable rise of temperature, just as rarefaction of a gas is accompanied by appreciable lowering of temperature. In the former case work is done in compressing the gas against its own pressure, and this energy appears as heat which raises the temperature of the gas. In the latter case the gas in expanding draws upon its own energy and so cools.

The thermal properties of gases are treated as a branch of mathematical physics under *HEAT* and *THERMODYNAMICS*, where also will be found discussed such experimental details as bear intimately upon the theory. The article *ATOM* contains a concise statement of the modern kinetic theory of gases; and in *CONSTITUTION OF BODIES* and *DIFFUSION* certain more special aspects of the same theory are regarded. For the mathematical theory see *MOLECULE*. The principles embodied in these articles have been assumed throughout the present article.

The cooling of a gas by its own expansion may be observed in one of its effects during exhaustion in an ordinary receiver. Frequently a cloud of minute drops of water—a veritable fog—forms in the exhausted air. The reason simply is that the air has become cooled below its dew-point, or the temperature corresponding to the pressure of water vapor present. If the receiver is first filled with dry air and then exhausted, no cloud forms. Also if the air is carefully filtered through cotton wool, no cloud forms, even though the air be thoroughly saturated with water vapor. This latter fact was established by Mr. Aitken in his beautiful series of experiments on dust, fogs, and clouds.¹ It thus appears that the formation of fog and cloud depends not only upon the humidity of the air but also upon the amount of dust in the air. The little particles of dust are necessary as nuclei upon which the vapor can begin to condense. The more numerous the dust particles the finer are the drops which form on them. As these coalesce into larger drops and fall, they bring down the dust nuclei with them; and hence the tendency of rain is to clear the atmosphere, and make conditions less favorable for the formation of more cloud and rain. Thus rain, fog, and dew all require for their formation a free solid surface, colder than the temperature of saturation, on which to con-

dense. In a dustless atmosphere no cloud can ever form.

It has been already pointed out that when a fluid is in motion it can no longer be regarded as even approximately possessing the properties of the ideal perfect fluid. The postulate that the stress between contiguous portions is perpendicular to the common interface cannot be for a moment admitted. A few examples will make this clear. Thus, if a vessel filled with a liquid be set in rotation, the liquid will soon be found to be rotating with the vessel; and if the motion of the vessel be stopped, the motion of the liquid inside will gradually subside. These phenomena show the existence of a stress tangential to the fluid elements, whereby the relative motion of the different parts of the system is gradually destroyed, until the vessel and its contents behave as one solid body. Again, a fluid stream flowing along a tube or canal moves fastest in the middle, slowest at the bounding walls, and with all possible intermediate speeds at intermediate places. This retardation, due in the first instance to the action of the walls upon the fluid in direct contact therewith, and then to the friction between the successive contiguous sheets of fluid, plainly implies the existence of tangential stress. The action of the wind in causing waves on the smooth surface of a sheet of water is a further illustration.

In the discussion of fluid motion, however, it is customary to consider first the properties of the ideal fluid in this respect. Under *HYDROMECHANICS*, and especially under *ATOM*, will be found the mathematical theory treated in full so far as the motion of a non-viscous fluid is concerned.

The possibility of setting up vortex-motion in a fluid depends upon its imperfection, upon the property of viscosity or fluid friction which is possessed by all known fluids. Some of the more obvious effects of this property have been already noticed. Its effects indeed are conspicuous wherever there is relative motion of the contiguous parts of a fluid. A current of air moving through a mass of air at rest soon loses its momentum; a solid body moving through still air likewise has its motion retarded. The loss of energy which a meteoric stone so suffers as it speeds through the atmosphere appears in the form of heat, which is sufficient to make the stone glow to incandescence or to the temperature of rapid combustion. The waves of rarefaction and condensation, which constitute sound physically, gradually decay in virtue of viscosity. It appears that the rate of this decay is quickest for the shortest waves; so that a sound after travelling through a long distance may lose its shriller constituents and so be modified and mellowed. It is viscosity also which supports the minute dust particles and cloud-forming drops of water in our atmosphere. These are bulk for bulk heavier than the atmosphere, and in tranquil air are slowly sinking. The slowness of their downward motion is directly due to the effect of fluid friction.

The term fluid friction is applied because of the similarity of its effects to the effects of friction between solid masses. Otherwise there need be no further resemblance. The true nature of friction between solid surfaces is not known; possibly, as suggested by Sir W. Thomson, it may be in great measure electrical. In the case of gases, however, the origin of friction is more apparent. Its laws can be deduced from the kinetic theory, and depend directly upon the principle of diffusion. According to the kinetic theory of gases, the molecules of a gas are in constant motion amongst themselves. Compared to their own dimensions, they are by no means closely packed, so that any individual molecule travels a comparatively large space between its encounters with other molecules. Any two contiguous regions are continually interchanging molecules. This diffusion of a gas into itself we have no means of measuring experimentally, as we cannot deal with the individual molecule. Suppose, however, that we have two contiguous layers of a gas flowing in parallel directions with different speeds. The general drift of molecules in the one layer is faster than in the other. But this difference will not prevent the individual molecules diffusing across the interface between the layers. Diffusion will go on freely. The result will be that the slower moving layer will on the whole gain momentum in the direction of its motion and the faster moving layer lose momentum. Thus, diffusion tends to the equalization of momentum between two contiguous regions, and the rate at which this takes place across unit area is the measure of the viscosity. Maxwell has proved² that the viscosity so measured is independent of the density of the gas when the temperature is constant;

¹ *Trans. Roy. Soc. Edin.*, 1880-81.

² *Phil. Mag.*, 1860, and *Phil. Trans.*, 1867.

whereas the relation between the viscosity and temperature depends upon the particular mode of action between the molecules when they approach each other.

The above definition of viscosity is not one which can be used in experimental determinations, since we cannot take account of the individual molecules of a gas. The coefficient of viscosity must be defined in terms of directly measurable quantities.

Maxwell has defined viscosity in these words: the viscosity of a substance is measured by the tangential force on unit of area of either of two horizontal planes at the unit of distance apart, one of which is fixed, while the other moves with unit of velocity, the space between being filled with the viscous substance. This is the dynamical definition. When the effects of viscosity on the internal motions of a fluid itself are being considered it is often more convenient to use the kinematical definition. It is given in terms of μ , the coefficient of viscosity, by the equation

$$\mu = \rho \nu,$$

where ρ is the density of the substance, and ν the kinematic viscosity.

The viscosity of fluids has been determined experimentally in three distinct ways—by flow of the fluid through tubes, by motion in the fluid of pendulums or vibrating disks, and by the oscillations of spheres filled with the fluid. The last was employed by Helmholtz and Von Piotrowski in their investigation of liquids,¹ but it is not applicable to the case of gases. Experiments on the flow through capillary tubes have been carried out by Poiseuille² for liquids, and by Graham,³ Meyer,⁴ Springmühl,⁴ and Puluj⁵ for gases. This, the transpiration method, is the most effective for comparing viscosities, which are directly proportional to the times of transpiration of the respective gases. There is, however, a little uncertainty as to the effect of the capillary tube,—so that, for measuring absolutely the viscosity for any one gas, the method is not so trustworthy as the second method. Here we may use either pendulums swinging through small arcs or disks oscillating in their own plane under the action of torsion. In both the measurement depends upon the rate at which the amplitude of oscillation diminishes.

Stokes, who first satisfactorily discussed the true nature of viscosity, tested the theory by a discussion⁶ of the pendulum experiments of Dubuat (1786), Bessel (1826), and Baily (1832). From Baily's results he calculated .000104 (in metric units) as the coefficient of viscosity of air. Meyer⁷ similarly deduced from Bessel's and Girault's⁸ experiments the values .000275 and .000384. It is not in the least surprising that these are all pretty wide of the true value, seeing that the experimenters had not the special problem of finding the viscosity before them.

Meyer, to whom we owe a very complete series of valuable memoirs on the subject, has more recently experimented⁹ with three different-sized pendulums. The values deduced for the viscosity were .000232, .000233, and .000184. The last number, given by the shortest pendulum, Meyer considers to be the best.

Maxwell¹⁰, Meyer, and Kundt¹¹ and Warburg¹² have experimented with oscillating disks. The methods of Maxwell and Meyer were so far similar that each used an arrangement of three horizontal circular disks, fixed centrally to the same vertical axis, and suspended by a torsion wire inside a receiver. The pressure and temperature of the air or gas inside could be adjusted to any desired values within certain limits. In Maxwell's apparatus, which Meyer adopted in his later researches, the moving disks vibrated between parallel fixed disks, which were perforated in the centre so as to allow the vertical suspended axis to pass freely through them. Each disk thus oscillated in its own plane between two parallel fixed surfaces. After the disks were set in position, and the air in the receiver brought to the desired temperature and pressure, the suspended disks were set in oscillation. This was effected magnetically, a small magnet fixed to the end of the suspended axis being acted upon by an external magnet suitably adjusted. Each disk, in its oscillations, dragged after it the layer of air in immediate contact with it; and in virtue of viscosity this oscillation was transmitted with diminishing amplitude from layer to layer until the fixed disks were reached. In

thus setting and sustaining in motion a mass of gas, the disk was doing work; and, if left to itself and to the action of the torsion suspension, it oscillated with gradually diminishing range until it came to rest. The viscosity of the air was not the only retarding influence. The torsion wire had also a coefficient of viscosity; and then there was a possible resistance due to the slipping of the fluid at the surfaces of the disks. These various effects were discriminated by suitable modifications. Thus by placing the oscillating disks in contact with each other, and setting two of the fixed disks at measured distances above and below, Maxwell reduced the number of surfaces in contact with the fluid, and so increased the relative importance of the effect due to the wire's viscosity. Again, by diminishing the distances between the fixed and oscillating disks, he made the conditions more favorable to the effect (if any) due to the slipping. This latter effect was found to be so small as to be almost within the errors of observation; consequently Maxwell felt himself warranted in calculating the coefficient of viscosity on the assumption that there was no slipping.

Maxwell's final result in metric (C. G. S.) units for the coefficient of viscosity of dry air is

$$\mu = .0001878(1 + .00365\theta),$$

where θ is the temperature in degrees Centigrade. Meyer's result is

$$\mu = .000190(1 - .0025\theta).$$

Maxwell found the effect of pressure to be inappreciable down to a pressure of 12 mm., and thus verified the deduction from theory.

Kundt and Warburg, in their experiments, used only one disk, which oscillated under the influence of a bifilar suspension between two fixed disks. They carried the pressure down to as low as 0.6 mm. At 20 mm. pressure the viscosity was the same as at the atmospheric pressure; but at lower pressures a slight diminution began to show itself. According to Crookes's later researches, this diminution becomes more and more marked at the higher exhaustions. The manner in which the viscosity then diminishes coincides remarkably with the manner in which the free path increases. It could not be expected that in such modified circumstances Maxwell's law would continue to apply. When the gas becomes so far rarefied that the mean free path of a molecule is not small compared to the space in which the gas is confined, the motion of the molecules cannot be treated statistically. Hence the deductions from a theory based upon the statistic method will no longer hold good.

Maxwell, Kundt and Warburg, and Crookes investigated by the disk method the viscosities of other gases, the values for which are compared below with the transpiration times of the same gases through capillary tubes. Maxwell also found that damp air, at 100 mm. pressure, and over water at about 20° C., was one-sixtieth less viscous than dry air at the same temperature. Kundt and Warburg found for water vapor, at 21° C. and 16 mm. pressure, the value

$$\mu = .0000975,$$

a little more than half that of air.

The results obtained by Meyer and Springmühl and by Puluj from their transpiration experiments agree well with those already given. In such experiments, however, the slipping of the gas over the solid surface has in certain circumstances a measurable effect. This slipping is measured by a certain coefficient, called the *Gleitungs-Koeffizient* by Helmholtz and Von Piotrowski. When this coefficient becomes appreciable, the gas in contact with the solid surface, instead of being at rest relatively to that surface, will be gliding over it with a finite velocity v . The circumstances of the motion will be very nearly the same if we remove a layer of the solid surface and replace it by fluid, the new surface of fluid in contact with the new solid surface being at rest. The thickness which must be so removed is the measure of the coefficient of slipping. Kundt and Warburg,¹³ in their experiments with glass tubes, found this coefficient for dry air at about 20° C. to be

$$8/p \text{ centimetres,}$$

where p is the pressure in dynes per square centimetre, which is nearly the same as in millionths of an atmosphere. The value for hydrogen on glass is $15/p$. Hence at ordinary pressures and moderate exhaustions this coefficient is very small, becoming appreciable only at low pressures.

The relation between viscosity and temperature is indicated at once by Maxwell's and Meyer's formulæ given above. According to Maxwell, the viscosity is proportional to the abso-

lute temperature. If in the kinetic theory the forces between the molecules are disregarded, that is, if the molecules are assumed to rebound after collision like elastic spheres, the relation deduced is that the viscosity varies as the square root of the absolute temperature. Hence the mutual molecular forces must be taken into account. Maxwell's experimental law would require any two molecules to repel each other with a force varying inversely as the fifth power of the distance. According to Meyer, however, the viscosity varies according to a power of the absolute temperature less than unity, but greater than one-half. His results in this respect are corroborated by those of Kundt and Warburg, Puluji, and other later experimenters. The .77 power is probably not far from the truth.¹ Hence we may give as the final value for the viscosity of dry air the expression

$$\mu = .000185 (1 + .0028\theta).$$

The following table gives the values for the different gases, as determined by the different investigators, the viscosity of air being taken as unity.

	Graham.	Maxwell.	Meyer.	Kundt and Warburg.	Crookes.
Air.....	1.000	1.000	1.000	1.000	1.000
Oxygen.....	1.112	...	1.095	...	1.119
Nitrogen.....	.971972

Carbonic acid	.840	.859	.851	.806	.920
Hydrogen....	.488	.516	.601	.488	.444

We do not here enter into the question of the thermodynamic properties of gases; enough to say that the relations between viscosity, diffusion, and thermal conductivity deduced by Maxwell from the kinetic theory have received remarkable corroboration from the experiments of Loschmidt, Stefan, Kundt and Warburg, and others. A discussion of the dynamical properties of gases would not, however, appear complete without mention of Crookes's so-called radiometer, even though these phenomena of high vacua are ultimately thermodynamic.

The typical form of the radiometer is a glass bulb, in which is hung a delicately poised arrangement of vanes. These, usually four in number, are fixed at the extremities of two light horizontal cross-rods, which are supported so as to be capable of easy rotation about a central vertical axis. The vanes or disks are set in vertical planes passing through the axis; and each has its one side bright, and the other blackened. For any rotation the motion of each vane is exactly alike; that is, either the bright faces all move first, or the dark faces do so. If the pressure of the gas inside the bulb is reduced to a very low exhaustion, the vanes under the action of light or heat will begin to rotate. The mere bringing the radiometer out of a dark region into daylight is enough to set up this rotation. In ordinary circumstances the dark faces are apparently repelled, and the vanes move round with their bright faces in advance.

The phenomenon is really a thermal one, as was demonstrated experimentally by Tait and Dewar.² Further, although it is most evident in high vacua (provided they are not too high), it can be produced in very moderate exhaustions by a suitable arrangement, as was long ago pointed out by Fresnel. Thus, if under the receiver of an ordinary air-pump a light disk be delicately poised near a parallel fixed surface, it will be apparently strongly repelled by this surface if the opposing surfaces are brought to different temperatures. This may be effectively done by means of a ray of sunlight. In this experiment, the essential condition is (as shown by Tait and Dewar) that the surfaces be at a distance comparable to the mean free path of the gaseous molecules. In Crookes's radiometer the free path is very long, and hence there is apparent repulsion between the blackened surfaces and the walls of the bulb. The reason simply is that, under the action of the radiant energy directed in upon the vanes, the dark faces, absorbing more energy, become warmer than the bright faces. Hence an inequality of temperature is produced in the highly rarefied gas, and this brings into existence a stress which displaces the vanes.

Liquid in the spheroidal state illustrates the same principle. That a drop of water may be supported over a hot surface without touching it requires an upward pressure. In other words, the vertical stress in the vapor and gas which separate the drop from the surface must be greater

than the ordinary gaseous pressure all round the drop. This stress exists because of the difference of temperature between the drop and the surface, so that the pressure in the thin layer of vapor and gas is slightly greater in the vertical than in any horizontal direction.

A general notion of the manner in which this stress is sustained may be obtained from the following consideration: According to the kinetic theory of gases, the mean speed of the molecules is a function of the temperature—the higher the temperature the greater the speed. Hence molecules, impinging upon a surface at a higher temperature, and in a direction more nearly perpendicular to it, will rebound from that surface with increased momentum. The simultaneous motion of the surface, as if repelled, is then somewhat analogous to the recoil of a cannon when fired. The whole investigation of the question is, however, by no means simple. Maxwell has discussed it with characteristic lucidity in his latest contribution³ to the dynamical theory of gases. He finds that, when inequalities of temperature exist at a given point in a gas, the pressure is not the same in all directions. Its value in any given direction, in so far as it depends upon the temperature inequality, is proportional to the space-rate of change of the space-variation of the temperature in that direction—that is, to the second differential coefficient of the temperature with respect to the given direction. Hence the pressure will be greatest along the line for which this differential coefficient is a maximum. It appears that the pressure so called into existence by a possible temperature inequality is very minute at ordinary hydrostatic pressures, but becomes considerable when the pressure of the gas is made very small. If the inequality of temperature throughout the gas is due to the presence of small bodies, whose temperatures differ from the temperature of the gas at a distance from them, then the small bodies will be acted upon by the stresses set up, provided they are of the same order of smallness as the mean free path of the molecules. In the case of two such small bodies, there will be apparent repulsion between them if the bodies are warmer than the air at a distance from them, and attraction if they are colder. If one is warmer and the other colder, the action may be either attractive or repulsive, according to the relative sizes of the bodies and their exact temperatures. These results are obtained by considering only the stresses normal to the solid surfaces. When the tangential stresses are taken into account, then it appears that inequality of temperature, when the flow of heat becomes steady, cannot produce other than equilibrium in the material system immersed in the gas. Hence Maxwell believes that the explanation of Crookes's phenomenon must depend ultimately upon the slipping of the gas over the solid surface. If such slipping be permitted, its effect will be to diminish the tangential stresses acting on the solid surface without affecting the normal stresses; and hence the equilibrium will be destroyed. In attempting to express the conditions to be satisfied by the gas at the solid surface, Maxwell is led to the consideration of the phenomenon discovered by Osborne Reynolds⁴ and named thermal transpiration. This phenomenon consists of a sliding of the gas over the surface of an unequally heated solid from the colder to the hotter parts. Maxwell considers the particular case of the slow steady flow of gas along a capillary tube, of circular section, the temperature of which varies steadily from point to point. The amount of gas which passes through any section depends both upon the rate of change of pressure and the rate of change of temperature in passing along the axis of the tube. If the pressure is uniform there will be a flow of gas from the colder to the hotter end. If there is no flow of gas, the pressure will increase from the colder to the hotter end. The case of uniform temperature is the ordinary case of transpiration through capillary tubes, as discussed experimentally by Graham, Meyer, Puluji, and Kundt and Warburg. The experimental investigation of the first two cases seems at present hopeless, on account of the minuteness of the quantities to be measured. Reynolds experimented, not on capillary tubes, but on the passage of the gas through a porous plate, the temperatures being different on the two sides. (C. G. K.)

PNEUMONIA, or inflammation of the substance of the lungs, manifests itself in several forms which differ from each other in their nature, causes, and results,—viz., (1) Acute Croupous or Lobar Pneumonia, the most common form of the disease, in which the inflammation affects a limited area, usually a lobe or lobes of the lung, and runs a rapid course; (2) Catarrhal Pneumonia, Broncho-Pneumonia, or Lobular

¹ [Professor P. E. Chase's theoretical estimate is .75—A.M. Ed.]

² *Proc. Roy. Soc. Edin.*, and *Nature*, 1875.

³ *Phil. Trans.*, 1879.

⁴ *Proc. Roy. Soc.*, 1879.

Pneumonia, which occurs as a result of antecedent bronchitis, and is more diffuse in its distribution than the former; (3) Interstitial Pneumonia or Cirrhosis of the lung, a more chronic form of inflammation, which affects chiefly the framework or fibrous stroma of the lung and is closely allied to phthisis.

Acute Croupous or Lobar Pneumonia.—This is the disease commonly known as inflammation of the lungs. It derives its name from its pathological characters, which are well marked. The changes which take place in the lung are chiefly three. (1) *Congestion*, or engorgement, the bloodvessels being distended and the lung more voluminous and heavier than normal, and of dark red color. Its air cells still contain air. (2) *Red Hepatization*, so called from its resemblance to liver tissue. In this stage there is poured into the air cells of the affected part an exudation consisting of amorphous fibrin together with epithelial cells and red and white blood corpuscles, the whole forming a viscid mass which occupies not only the cells but also the finer bronchi, and which speedily coagulates, causing the lung to become firmly consolidated. In this condition the cells are entirely emptied of air, their bloodvessels are pressed upon by the exudation, and the lung substance, rendered brittle, sinks in water. The appearance of a section of the lung in this stage has been likened to that of red granite. It is to the character of the exudation, consisting largely of coagulable fibrin, that the term croupous is due. (3) *Gray Hepatization*. In this stage the lung still retains its liver-like consistence, but its color is now gray, not unlike the appearance of gray granite. This is due to the change taking place in the exudation, which undergoes resolution by a process of fatty degeneration, pus formation, liquefaction, and ultimately absorption,—so that in a comparatively short period the air vesicles get rid of their morbid contents and resume their normal function. This is happily the termination of the majority of cases of croupous pneumonia, yet it occasionally happens that this favorable result is not attained, and that further changes of a retrograde kind take place in the inflamed lung in the form of suppuration and abscess or of gangrene. In such instances there usually exists some serious constitutional cause which contributes to give this unfavorable direction to the course of the disease. Further, pneumonia may in some instances become chronic, the lung never entirely clearing up, and it may terminate in phthisis. Pneumonia may be confined to a portion or the whole of one lung, or it may be double, affecting both lungs, which is a serious and often fatal form. The bases or middle of the lungs are the parts most commonly inflamed, but the apex is sometimes the only part affected. The right lung is considerably more frequently the seat of pneumonia than the left lung.

Many points in the pathology of this form of pneumonia remain still to be cleared up. Thus, there is a growing opinion that it is not a simple lung inflammation, as was formerly supposed, but that, as regards its origin, progress, and termination, it possesses many of the characters of a fever or of a constitutional affection. An interesting and important fact in this connection is the recent discovery by Friedländer and others of a micro-organism or bacillus in the blood, lungs, and other tissues in cases of pneumonia, which, when inoculated into certain lower animals, is followed by the symptoms and appearances characteristic of that disease. While it must be confessed that such inoculation experiments carried on in rabbits, guinea pigs, or mice are scarcely sufficient by themselves to settle the question of the specific and infectious nature of pneumonia as it affects the human subject, yet they are of distinct value as evidence pointing in that direction. Further, there are numerous instances on record in which this disease has appeared to spread as an epidemic in localities or in families in such a way as strongly to suggest the idea of infectiveness. Cases of this kind, however, are open to the question as to whether there may not coexist some other disease, such as a fever, of which the pneumonia present is but a complication. The whole subject of the pathology of pneumonia is still under investigation, and all that can in

the meantime be affirmed is that it presents many features which render its phenomena unlike those of an ordinary inflammation, while on the other hand it has strong analogies to some of the specific fevers. As regards known causes, in the vast majority of instances, an attack of pneumonia comes on as the result of exposure to cold as the exciting agent, while such conditions as fatigue and physical or mental depression are often traceable as powerful predisposing influences.

The symptoms of acute pneumonia are generally well marked from the beginning. The attack is usually ushered in by a rigor (or in children a convulsion), together with vomiting and the speedy development of the febrile condition, the temperature rising to a considerable degree— 101° to 104° or more. The pulse is quickened, and there is a marked disturbance in the respiration, which is rapid, shallow, and difficult, the rate being usually accelerated to some two or three times its normal amount. The lips are livid and the face has a dusky flush, pain in the side is felt, especially should any amount of pleurisy be present, as is often the case. Cough is an early symptom. It is at first frequent and hacking, and is accompanied with a little tough colorless expectoration, which soon, however, becomes more copious and of a rusty brown color, either tenacious or frothy and liquid. Microscopically this consists mainly of epithelium, casts of the air cells, and fine bronchi, together with granular matter and blood and pus corpuscles.

The following are the chief physical signs in the various stages of the disease. In the stage of congestion fine crackling or crepitation is heard over the affected area; sometimes there is very little change from the natural breathing. In the stage of red hepatization the affected side of the chest is seen to expand less freely than the opposite side; there is dulness on percussion, and increase of the vocal fremitus; while on auscultation the breath sounds are tubular or bronchial in character, with, it may be, some amount of fine crepitation in certain parts. In the stage of gray hepatization the percussion note is still dull and the breathing tubular, but crepitations of coarser quality than before are also audible. These various physical signs disappear more or less rapidly during convalescence. With the progress of the inflammation the febrile symptoms and rapid breathing continue. The patient during the greater part of the disease lies on the back or on the affected side. The pulse, which at first was full, becomes small and soft owing to the interruption to the pulmonary circulation. Occasionally slight jaundice is present, due probably to a similar cause. The urine is scanty, sometimes albuminous, and its chlorides are diminished. In favorable cases, however severe, there generally occurs after six or eight days a distinct crisis, marked by a rapid fall of the temperature accompanied with perspiration and with a copious discharge of lithates in the urine. Although no material change is as yet noticed in the physical signs, the patient breathes more easily, sleep returns, and convalescence advances rapidly in the majority of instances. In unfavorable cases death may take place either from the extent of the inflammatory action, especially if the pneumonia is double, from excessive fever, from failure of the heart's action or general strength at about the period of the crisis, or again from the disease assuming from the first a low adynamic form with delirium and with scanty expectoration of greenish or "prune juice" appearance. Such cases are seen in persons worn out in strength, in the aged, and especially in the intemperate. Death may also take place later from abscess or gangrene of the lung; or again recovery may be imperfect and the disease pass into a chronic pneumonia.

The treatment of acute pneumonia, which at one time was conducted on the antiphlogistic or lowering principle, has of late years undergone a marked change; and it is now generally held that in ordinary cases very little active interference is called for, the disease tending to run its course very much as a specific fever. The employment of blood-letting once so general is now only in rare instances resorted to; but, just as in pleurisy, pain and difficulty of breathing may sometimes be relieved by the application of a few leeches to the affected side. In severe cases the cautious employment of aconite or antimony at the outset appears useful in diminishing the force of the inflammatory action. Warm applications in the form of poultices to the chest give comfort in many cases. Cough is relieved by expectorants, of which those containing carbonate of ammonia are especially useful. Any tendency to excessive fever may often be held in check by quinine. The patient should be fed with milk, soups, and other light forms of nourishment. In the later period of the disease stimulants may be called for, but most reliance is to be placed on nutritious aliment. After the acute symptoms disappear

counter-irritation by iodine or a blister will often prove of service in promoting the absorption of the inflammatory products. After recovery is complete the health should for some time be watched with care.

When pneumonia is complicated with any other ailment or itself complicates some pre-existing malady, it must be dealt with on principles applicable to these conditions as they may affect the individual case.

Catarrhal or Lobular Pneumonia (Broncho-Pneumonia) differs from the last in several important pathological and clinical points. Here the inflammation is more diffuse and tends to affect lobules of lung tissue here and there, rather than one or more lobes as in croupous pneumonia. At first the affected patches are dense, non-crepitant, with a bluish red appearance tending to become gray or yellow. Under the microscope the air vesicles and finer bronchi are crowded with cells, the result of the inflammatory process, but there is no fibrinous exudation such as is present in croupous pneumonia. In favorable cases resolution takes place by fatty degeneration, liquefaction, and absorption of the cells, but on the other hand they may undergo caseous degenerative changes, abscesses may form, or a condition of chronic interstitial pneumonia be developed in both of which cases the condition passes into one of phthisis. Evidence of previous bronchitis is usually present in the lungs affected with catarrhal pneumonia. In the great majority of instances catarrhal pneumonia occurs as an accompaniment or sequel of bronchitis either from the inflammation passing from the finer bronchi to the pulmonary air vesicles, or from its affecting portions of lung which have undergone collapse. It occurs most frequently in children, and is often connected with some pre-existing acute ailment in which the bronchi are implicated, such as measles or whooping cough. It likewise affects adults and aged people in a more chronic form as the result of bronchitis. Sometimes a condition of catarrhal pneumonia may be set up by the plugging of one or more branches of the pulmonary artery, as may occur in heart disease, pyæmia, etc.

The symptoms characterizing the onset of catarrhal pneumonia in its more acute form are the occurrence during an attack of bronchitis of a sudden and marked elevation of temperature, together with a quickened pulse and increased difficulty in breathing. The cough becomes short and painful, and there is little or no expectoration. The physical signs are not distinct, being mixed up with those of the antecedent bronchitis; but, should the pneumonia be extensive, there may be an impaired percussion note with tubular breathing and some bronchophony.

Acute catarrhal pneumonia must be regarded as a condition of serious import. It is apt to run rapidly to a fatal termination, but on the other hand a favorable result is not unfrequent if it is recognized in time to admit of efficient treatment. In the more chronic form it tends to assume the characters of chronic phthisis (see PHTHISIS). The treatment is essentially that for the more severe forms of bronchitis (see BRONCHITIS), where, in addition to expectorants, together with ammoniacal, ethereal, and alcoholic stimulants, the maintenance of the strength by good nourishment and tonics is clearly indicated. The breathing may often be relieved by light warm applications to the chest and back. Convalescence is often prolonged, and special care will always be required in view of the tendency of the disease to develop into phthisis.

Chronic Interstitial Pneumonia or Cirrhosis of the Lung is a slow inflammatory change affecting chiefly one portion of the lung texture, viz., its fibrous stroma.

The changes produced in the lung by this disease are marked chiefly by the growth of nucleated fibroid tissue around the walls of the bronchi and vessels, and in the intervesicular septa, which proceeds to such an extent as to invade and obliterate the air cells. The lung, which is at first enlarged, becomes shrunken, dense in texture, and solid, any unaffected portions being emphysematous; the bronchi are dilated, the pleura thickened, and the lung substance often deeply pigmented, especially in the case of miners, who are apt to suffer from this disease. In its later stages

the lung breaks down, and cavities form in its substance as in ordinary phthisis.

This condition is usually present to a greater or less degree in almost all chronic diseases of the lungs and bronchi, but it is specially apt to arise in an extensive form from pre-existing catarrhal pneumonia, and not unfrequently occurs in connection with occupations which necessitate the habitual inhalation of particles of dust, such as those of colliers, flax-dressers, stone-masons, millers, etc.

The symptoms are very similar to those of chronic phthisis (see PHTHISIS), especially increasing difficulty of breathing, particularly on exertion, cough either dry or with expectoration, sometimes copious and fetid. In the case of coal-miners the sputum is black from containing carbonaceous matter.

The physical signs are deficient expansion of the affected side—the disease being mostly confined to one lung—increasing dullness on percussion, tubular breathing, and moist sounds. As the disease progresses retraction of the side becomes manifest, and the heart and liver may be displaced. Ultimately the condition both as regards physical signs and symptoms takes the characters of the later stages of phthisis with colliquative symptoms, increasing emaciation, and death. Occasionally dropsy is present from the heart becoming affected in the course of the disease. The malady is usually of long duration, many cases remaining for years in a stationary condition and even undergoing temporary improvement in mild weather, but the tendency is on the whole downward.

The treatment is conducted on similar principles to those applicable in the case of phthisis. Should the malady be connected with a particular occupation, the disease might be averted or at least greatly modified by early withdrawal from such source of irritation. (J. O. A.)

PNOM-PENH, the capital of CAMBODIA (see vol. iv. p. 641).

PO, the largest river of Italy, traverses the whole length of the great plain between the Alps and the Apennines, which was in the Miocene period an arm of the sea connecting the Adriatic with the Mediterranean by what is now the Col d'Altare or Col di Cadibona and has gradually been filled by detritus from the surrounding highlands. That its course lies much nearer the Apennines than the Alps is evidently due to the fact that the tributaries from the loftier range on the north, whether in the form of glacier or stream, have all along been much more powerful than the tributaries from the south. The total length of the river from its conventional source to the mouth of the principal channel is 417½ miles, and the area of its basin, which includes portions of Switzerland and Austria, is estimated at 26,798 square miles. The general course of the river has been already described in Italy (vol. xiii. p. 444).

The Po forms a very extensive delta, and is probably one of the most active of all rivers in the work of denudation. Prony has calculated that between 1200 and 1600 the delta advanced at the rate of 80 feet per annum; and between 1600 and 1804 the rate is said to have been as much as 230 feet. This advance has naturally been attended by great changes in the course and size of the several channels. Ravenna, for example, once a great port, now stands on dry land 4 miles from the sea. The modern lagoons of Comacchio, which stretch southwards from the delta, are being artificially reclaimed by the help of the alluvial deposits.

In its ordinary condition the Po has a depth between Pancelirei and the mouth of the Ticino of from 6 to 10 feet, and between the mouth of the Lambro and that of the Adda of about 14 or 15 feet. Lower down the depth occasionally exceeds 40 feet. Permanent fords exist only in the upper Po, and between the mouths of the Ticino and the Lambro. In times of great drought the bed is quite dry at Rovello, and fords appear below Casalmaggiore and at Borgoforte, where the French and Germans crossed in 1796, 1807, 1813, and 1814; but in general the river forms a complete barrier both to foot and horse. The principal points where crossing is effected by ferries or bridges are *Moncalieri, Turin, *Casale Monferrato, Frassinato, *Valenza, *Mezzana Corti, *Piacenza, Cremona, *Casalmaggiore,

Brescello, *Borgoforte, San Benedetto, Ostiglia, *Occhiobello, Pontelagoscuro, Francolino. Railway bridges exist at the places distinguished by an asterisk.

The river in general is at its fullest in May and June, and at its lowest in January (see details in Lombardini's elaborate study on the lower Po in *Memorie del Reale Istituto Lombardo*, Milan, 1870). The ordinary floods on the Po are attended with little danger; but at intervals sometimes of a few, sometimes of many years, they become events of the gravest national concern. Those of 1651 and 1705 are among the most destructive recorded in history, and in the present century the more memorable are those of 1839, 1846, 1855, 1857, 1868, 1872, and 1879. In 1872, 1150 square miles of country between the Reno and the Adige were submerged, the district about Modena was turned into a lake, the people of Revere saved the rest of the town only by sacrificing the front row of houses to form a temporary embankment, and it was only by the wisely conducted energy of its inhabitants that Ostiglia was kept from destruction. During April and May, 1879, the rainfall was exceptionally heavy, the quantity for May alone being equal to more than a third of the annual total. The result was a rise in all the tributaries of the Po, and on May 30 the flood in the main river was 21 feet above low water at Mezzana Corti. A breach 720 feet long in the embankment between Bonizzo and Borgofranco caused the submergence of 155 square miles in the provinces of Mantua, Modena, and Ferrara, and involved in its repair a national expenditure of £53,460.

Of the £5,902,981 (\$28,688,487.66) devoted by the government to the regulation of the rivers of Italy in the twenty years 1861-1880, £2,257,872 (\$10,793,257.90) had to be appropriated to the Po and its tributaries. Nowhere in Europe except in Holland has the system of embankment been carried to such perfection on so extensive a scale. A wide bed for the river at its height is enclosed for long distances by a massive master-dyke or *froldo*, and in the space between this and the ordinary channels suitable areas are often enclosed by secondary dykes or *golene*. The following figures show the extent of the system in 1880:

	Length of Embankment.	Froldo.	Golena.
	Miles.	Miles.	Miles.
Po.....	509.97	71.93	438.03
Adige.....	156.12	109.81	46.30
Tartaro and Po di Levante..	148.30	35.62	112.68
Reno.....	146.72	33.68	113.04
Panaro.....	100.34	48.26	52.07
Secchia.....	89.75	28.21	61.54

Recent researches (see Helbig, *Die Italiker in der Po-Ebene*, Leipsic, 1879) show that the lower valley of the Po was at an early period occupied by people of the Palæolithic and Neolithic stages of civilization, who built houses on piles along the swampy borders of the streams. It is possible that even they may have begun by crude dykes the great system by which the waters are now controlled; at least it is certain that these works date their origin from pre-Roman antiquity. Pliny refers them to the Etruscans, who occupied the country before the arrival of the Gauls. The reclaiming and protecting of the riparian lands went on rapidly under the Romans, and in several places the rectangular divisions of the ground, still remarkably distinct, show the military character of some of the agricultural colonies. During the time of the barbarian invasion much of the protective system was allowed to fall into decay; but the later part of the Middle Ages saw the works resumed and carried out with great energy, so that the main features of the present arrangement were in existence by the close of the 15th century.

The usual name for the Po among Greek and Latin authors was Padus (Πάδος); but the Greek writers of the empire began to apply to it the poetic name of Eridanus, familiar in the Phaethon myth.

POCHARD, POKARD, or POKER,¹ names properly belonging to the male of a species of Duck (the female of which is known as the Dunbird), the *Anas ferina* of Linnæus, and *Fuligula* or *Æthya ferina*

of later ornithologists—but names very often applied by writers in a general way to most of the group or Subfamily *Fuligulina*, commonly called Diving or Sea-Ducks (cf. DUCK, vii. p. 436). The Pochard in full plumage is a very handsome bird, with a coppery-red head, on the sides of which sparkle the ruby irides of his eyes, relieved by the grayish-blue of the basal half of his broad bill, and the deep black of his gorget, while his back and flanks appear of a light gray, being really of a dull white closely barred by fine undulating black lines. The tail-coverts both above and below are black, the quill feathers brownish-black, and the lower surface of a dull white. The Dunbird has the head and neck reddish-brown, with ill-defined whitish patches on the cheeks and chin, the back and upper tail-coverts dull brown, and the rest of the plumage, except the lower tail-coverts, which are brownish-gray, much as in the Pochard. This species is very abundant in many parts of Europe, northern Asia, and North America, generally frequenting in winter the larger open waters, and extending its migrations to Barbary and Egypt, but in summer retiring northward and inland to breed, and is one that certainly seems to have profited by the legislative protection lately afforded to it in Britain, for, whereas during many years it had but a single habitual breeding-place left in England, it is now known to have several, to some of which it resorts in no inconsiderable numbers. American examples seem to be slightly larger and somewhat darker in color, and hence by some writers have been regarded as specifically distinct under the name of *Fuligula americana*; but America has a perfectly distinct though allied species in the celebrated Canvas-back Duck, *F. vallisneriana*, a much larger bird, with a longer, higher, and narrower bill, which has no blue at the base, and, though the plumage of both, especially in the females, is very similar, the male Canvas-back has a darker head, and the black lines on the back and flanks are much broken up and further asunder, so that the effect is to give these parts a much lighter color, and from this has arisen the bird's common though fanciful name. Its scientific epithet is derived from the freshwater plant, a species of *Vallisneria*, usually known as "wild celery," from feeding on which its flesh is believed to acquire the delicate flavor that is held in so great a repute. The Pochard and Dunbird, however, in Europe are in much request for the table (as the German name of the species, *Tafelente*, testifies), though their quality in this respect depends almost wholly on the food they have been eating, for birds killed on the sea-coast are so rank as to be almost worthless, while those that have been frequenting fresh water are generally well-tasted.²

Among other species nearly allied to the Pochard that frequent the northern hemisphere may be mentioned the Scaup-Duck, *F. marila*, with its American representative *F. affinis*, in both of which the male has the head black, glossed with blue or green; but these are nearly always uneatable from the nature of their food, which is mostly gathered at low tide on the "scaups" or "scalps,"³—as the banks on which mussels and other marine molluscs grow are in many places termed. Then there is the Tufted Duck, *F. cristata*—black with a crest and white flanks—and its American equivalent *F. collaris*, and the White-eyed or Castaneous Duck, *F. nyroca*, and the Red-crested Duck, *F. rufigula*—both peculiar to the Old World, and the last, conspicuous for its red bill and legs, well known in India. In the southern hemisphere the genus is represented by three species, *F. capensis*, *F. australis*, and *F. novæ-zealandiæ*, whose respective names indicate the country each inhabits, and in South America exists a somewhat divergent form which has been placed in a distinct genus as *Metopiana peposaca*.

Generally classed with the *Fuligulina* is the small group known as the Eiders,⁴ which differ from them in several

¹ The derivation of these words, in the first of which the *ch* is pronounced hard, and the *o* in all of them generally long, is very uncertain. Cotgrave has *Pocheculier*, which he renders "Shoueler," now-a-days the name of a kind of Duck, but in his time meaning the bird we commonly call SPOONBILL (*g.e.*). Littré gives *Pochard* as a popular French word signifying drunkard. That this word would in the ordinary way become the English Pochard or Poker may be regarded as certain; but then it is not known to be used in French as a bird's name.

² The plant known in some parts of England as "willow-weed"—not to be confounded, as is done by some writers, with the willow-wort (*Epilobium*)—one of the many species of *Polygonum*, is especially a favorite food with most kinds of Ducks, and to its effects is attributed much of the fine flavor which distinguishes the birds that have had access to it.

³ Cognate with *scallop*, and the Dutch *schelp*, a shell.

⁴ Icelandic, *Edur*.

respects: the bulb at the base of the trachea in the male, so largely developed in the members of the genus *Fuligula*, and of conformation so similar in all of them, is here much smaller and wholly of bone; the males take a much longer time, two or even three years, to attain their full plumage, and some of the feathers on the head, when that plumage is completed, are always stiff, glistening, and of a peculiar pale-green color. This little group of hardly more than half a dozen species may be fairly considered to form a separate genus under the name of *Somateria*. Many authors indeed have—unjustifiably, as it seems to the present writer—broken it up into three or four genera. The well-known Eider, *S. mollissima*, is the largest of this group, and, beautiful as it is, is excelled in beauty by the King-Duck, *S. spectabilis*, and the little *S. stelleri*. Space fails here to treat of the rest, but the sad fate which has overtaken one of them, *S. labradoria*, has been before mentioned (BIRDS, vol. iii. p. 637); and only the briefest notice can be taken of a most interesting form generally, but obviously in error, placed among them. This is the Logger-head, Racehorse, or Steamer-Duck, *Micropterus* (or more properly *Tachyeres) cinereus* of the Falkland Islands and Straits of Magellan—nearly as large as a tame Goose, and subject to the, so far as known, unique peculiarity of losing its power of flight after reaching maturity. Its habits have been well described by Darwin in his *Journal of Researches*, and its anatomy is the subject of an excellent paper in the Zoological Society's *Transactions* (vii., pp. 493–501, pis. lvi.iii.–lxii.) by Prof. R. O. Cunningham. (A. N.)

POCOCK, EDWARD (1604–1691), one of the most eminent of English Oriental and Biblical scholars, was born in 1604, the son of a Berkshire clergyman, and received his education up to his fourteenth year at the free school of Tame in Oxfordshire and then at Oxford, where he became scholar of Corpus Christi College in 1620 and fellow in 1628. The foundation of his Eastern learning was laid at Oxford under Matthias Pasor, son of the better known George Pasor, who had been driven to England by the troubles in the Palatinate, and he subsequently received instruction from the learned W. Bedwell. The first fruit of his studies was an edition from a Bodeleian MS. of the four New Testament epistles which were not in the old Syriac canon, and were not contained in European editions of the Peshito. This was published at Leyden at the instigation of G. Vossius in 1630, and in the same year Pocock sailed for Aleppo as chaplain to the English factory. At Aleppo he made himself a profound Arabic scholar and collected many valuable MSS. At this time Laud was busy with the learned collections with which he afterwards enriched his university, and Pocock became known to him as one who could help his schemes. A correspondence ensued, and ultimately Laud resolved to set up an Arabic chair at Oxford and to invite Pocock home to fill it. The invitation was accepted, and the lecturer entered on his duties on August 10, 1636, but next summer sailed again for Constantinople with the archbishop's consent to prosecute further studies and collect more books, and remained there for about three years. When he returned to England Laud was in the Tower; and, though he had taken the precaution to place the Arabic chair on a permanent footing, a time soon followed in which to have been a protégé of the archbishop was a dangerous distinction. Pocock does not seem to have been an extreme churchman or to have meddled actively in politics, but his views were decided enough to make him objectionable to the Parliamentary party, and to bring on him many troubles not only at Oxford but in his parish of Childrey, where he accepted a college living in 1643. On the other hand his rare scholarship and personal qualities raised him up influential friends even among men of the opposite party in church and State, foremost among these being Selden. Through the offices of these friends he was even advanced in 1648 to the chair of Hebrew, though as he could not take the engagement of 1649 he lost the emoluments of the place very soon after, and did not recover them till the Restoration. All these cares seriously hampered Pocock in his studies, as he complains in the

preface to his *Eutychiuss*; he seems to have felt most deeply the attempts to remove him from Childrey, where he attended to his parochial work with the same modest and diligent zeal that marks him as a scholar. But he continued to work hard; in 1649 he published the *Specimen Historiæ Arabum*, that is, a short account of the origin and manners of the Arabs, taken from Barhebræus (Abulfaraj), with a mass of learned notes from a vast number of MS. sources which are still highly valuable to the student of Oriental history. This was followed in 1655 by the *Porta Mosis*, extracts from the Arabic commentary of Maimonides on the Mishna, with translation and very learned notes;¹ and in 1656 by the annals of *Eutychiuss* in Arabic and Latin, a work of great value which has not found an editor since. He also gave assistance to Walton's polyglott, and the preface to the various readings of the Arabic Pentateuch is from his hand. After the Restoration Pocock's political and pecuniary troubles were removed, but the reception of his complete edition of the Arabic history of Barhebræus (*Greg. Abulfaragii Historia Dynastiarum*), which he dedicated to the king in 1663, showed that the new order of things was not very favorable to profound scholarship. After this his most important works were his English commentaries on Micah (1677), Malachi (1677), Hosea (1685), Joel (1691)—admirable in every way, and still thoroughly worth reading. An Arabic translation of Grotius *De Veritate* which appeared in 1660 may also be mentioned as a proof of Pocock's interest in the propagation of Christianity in the East. This was an old plan which he had talked over with Grotius at Paris on his way back from Constantinople.

Pocock married in 1646 and died in 1691. One of his sons, Edward, published several contributions to Arabic literature—a fragment of Abdullatif's description of Egypt and the *Philosophus Autodidactus* of Ibn Tofail.

The theological works of Pocock were collected in 2 vols. folio, in 1740, with a tedious but curious account of his life and writings by L. Twells.

POCOCKE, RICHARD (1704–1765), distantly related to the preceding, was the son of Richard Pococke, head master of the free school at Southampton, where he was born in the year 1704. He received his school learning under his father, and his academical education at Corpus Christi College, Oxford, where he took his various degrees. He commenced his travels in the East in 1737, and returned in 1742. In 1743 he published his *Observations on Egypt*, under the general title of *A Description of the East and Some Other Countries*. In 1744 he was made precentor of Waterford; and in 1745 he printed the second volume of his travels, under the title of *Observations on Palestine, or the Holy Land, Syria, Mesopotamia, Cyprus, and Candia*. In 1756 Pococke was promoted to the bishopric of Ossory; in July, 1765, he was translated to the see of Meath, and in September following he died suddenly of apoplexy, whilst engaged in visiting his diocese.

PODIEBRAD, GEORGE OF (1420–1471), king of Bohemia, was the son of Herant of Podiebrad, a Bohemian nobleman, and was born 6th April, 1420. After the death of the emperor Sigismund he took up arms against Albert of Austria, who was finally compelled to raise the siege of Tabor and retreat to Prague. On the death of Patzek in 1444 George of Podiebrad became the recognized head of the Calixtines or Utraquists, and was chosen to represent them as one of the two governors of Bohemia during the minority of Ladislaus the son of Albert. After some years of conflict with the Catholic party he was in 1451 recognized as sole governor. Following a policy of conciliation, he made no opposition to the accession of Ladislaus in 1453, who repeated to the Bohemians

¹ Pocock was justly impressed with the fact that the best parts of Rabbinic literature belong to the Jews who wrote in Arabic.

the promises made by Sigismund. The Catholic predilections of Ladislaus rendered him in a great measure blind to the obligations into which he had entered, but the result was silently to strengthen the influence of George of Podiebrad, who on the death of Ladislaus in 1457 was chosen king of Bohemia (March, 1458), and on May 7, 1459, was crowned by Catholic bishops, promising on his part due obedience to the church. This effort at a reconciliation was, however, soon seen to be futile. In 1462 Pope Pius II. refused the ratification of the *compactata*, agreed upon in 1433, and still no basis of a settlement had been found when Pius died in November, 1464. The new pope, Paul II., at once brought matters to a crisis by issuing against George of Bohemia the ban of excommunication, and a summons for a crusade to crush his authority. To this George replied by a letter of grievances to kings and princes, and an appeal to a general council. The summons of Paul II. did not awaken any general response, and, although Matthias of Hungary was proclaimed king of Bohemia, George successfully resisted all attempts to wrest from him his dominion, and in July, 1470, Matthias agreed to an armistice. George died March 22, 1471, and was succeeded by Ladislaus, eldest son of Casimir IV.

PODOLIA, a government of southwestern Russia, having Volhynia on the N., Kieff and Kherson on the E. and S., Bessarabia on the S.W., and Galicia (Austria) on the W., from which last it is separated by the Zbrutch, or Rodvotcha, a tributary of the Dniester. It has an area of 16,223 square miles, extending for 200 miles from northwest to southeast on the left bank of the Dniester. In the same direction two ranges of hills, nearly parallel, and separated by the Bug, traverse the government; they are ramifications of the so-called "Avratynsk heights." One of these ranges runs parallel to the Dniester at a distance of some 40 miles, and reaches a maximum elevation of 1185 feet in the northern districts, sending a lateral branch to the Dniester at Kamenets. The other range, entering also from the northwest, follows the boundaries of the government of Kieff on the left bank of the Bug; its highest eminences do not exceed 1050 feet. The geological structure of Podolia is in accordance with the above-mentioned orographical features; a strip of land to the east of the Bug belongs to the Huronian granitic region of the Dniester, granites and aprites (granulites) appearing also in the bed of the Bug, and being covered with Quaternary deposits only, while the remainder of the province, towards the west, is covered with Tertiary (Miocene). In the deep valleys of the rivers, older formations—the cretaceous and Silurian, as also sometimes the granites—appear from beneath the Tertiary. The whole is covered with a boulder-clay, mostly containing débris of the local rocks, and with loess, the origin of both still being a subject of controversy among Russian geologists. Two large rivers, with numerous tributaries, water the government,—the Dniester, which forms its boundary with Bessarabia and is navigable throughout its length, and the Bug, which flows almost parallel to the former in a higher, sometimes swampy valley, and is broken at several places by strong rapids. The Dniester is an important channel for trade, no less than 30,000 tons of corn, spirits, and timber being exported every year from its eighteen ports, the chief of which are Moghileff, Kalus, Zhvanets, and Porog. The rapid smaller tributaries of the Dniester supply numerous flour-mills with motive power. The soil is almost throughout "black-earth," and Podolia is one of the most fertile provinces of Russia. Forests cover about 245,000 acres. Marshes occur only on the Bug. The climate is moderate, the average temperature of the year at Kamanets being 48.3° (24.5° in January, 69° in July).

The population, which was 2,242,650 in 1881, and is now estimated at 2,335,000, consists chiefly of Little Russians, Poles (about 12 per cent.), and Jews (about 13 per cent.), of whom some 9000 are agriculturists. There are besides about 300 Armenians, some 2500 Germans, and nearly 45,000 Moldavians. There are many Nonconformists among the Russians, Tultchin being the seat of their bishops and a centre of propaganda. The chief occupation is agriculture, 56 per cent. of the surface being under crops, and the average harvests of recent years reaching 3,382,000 qrs. [27,056,000 bu.] of corn and 453,000 qrs. [3,624,000 bu.] of potatoes. The chief crops are wheat, Indian corn, oats, rye, potatoes, and beetroot. No less than 2,500,000 qrs. [20,000,000 bu.] of corn are exported every year to Austria or to Odessa. Gardening is in a flourishing condition, and fruit is largely exported to the interior; the vine is cultivated, mostly for grapes, but partly also for wine; the culture of tobacco is a considerable source of income. Cattle-breeding is less developed, owing to a want of grazing grounds and meadows. Horned cattle—a mixture of the Hungarian and Bessarabian breeds—are, however, exported to Moscow and to Austria. Finer breeds of sheep are raised in the proportion of two-fifths of the whole number. In 1881 Podolia had 169,000 horses, 432,000 horned cattle, 513,000 sheep, and 307,000 swine. Bees are kept throughout the territory, and honey is exported. Sericulture has developed considerably of late years, and will probably take an important position, owing to the climate. Agriculture and cattle-breeding are on the whole declining. Lately manufactures have grown rapidly. In 1865 they already employed 14,450 hands, but produced only to the value of 5,334,000 roubles [\$4,107,180]. Fourteen years later they employed more than 20,000 hands, and their yearly production was valued at 29,411,000 roubles [\$22,646,470]. The first place is taken by beetroot sugar works (15,800 hands; £1,038,000 [\$5,044,680]), after which come distilleries (£1,372,000 [\$6,667,920]), sugar refineries (£287,100 [\$1,395,306]), flour-mills (£134,500 [\$653,670]), tobacco manufacture (£32,200 [\$156,492]), the woollen cloth industry, and several smaller manufactures spirits, leather, soap, candles, machinery, and agricultural implements. An active trade is carried on with Austria, especially through the Isakovets and Gusyatin custom-houses,—corn, cattle, horses, skins, wool, linseed, and hemp seed being exported, in exchange for wooden wares, linen, woollen stuffs, cotton, glass, and agricultural implements. The trade with the interior is also carried on very briskly, especially at the twenty-six fairs, the aggregate returns of which exceed 3,000,000 roubles [\$2,310,000]; the chief are at Balta and Yarmolintzy. Podolia is traversed by a railway which runs parallel to the Dniester, from Lemberg to Odessa, and has two branch lines to Kieff (from Zhmerinka) and to Poltava (from Balta). Primary schools are better than in many central provinces of Russia, and Kamanets-Podolsk has of late years begun to show some development of intellectual life. The publications of the provincial assembly and the memoirs of the historical and statistical committee of the government are especially worthy of notice. Podolia is divided into twelve districts, the chief towns of which are—Kamanets-Podolsk, capital of the government (22,650), Balta (22,450), Bratslaff (5550), Gaysin (9450), Letitcheff (4800), Litin (7100), Moghileff-on-Dniester (18,150), Novaya Ushitsa (4500), Olgopol (6950), Proskuroff (11,750), Vinnitsa (18,800), and Yampol (4300). The following towns have municipal institutions:—Bar (7800), Khmelnik (7800), Nemiroff (5450, has a lyceum), Salnitsa (3300), Staraya Ushitsa (3700), Verbovets (2150), and Tultchin (11,220), besides many *myestetchki*, having Polish municipal institutions.

History.—The country has been inhabited since the beginning of the Neolithic period. In the 5th century B.C. it was already known to geographers, and Herodotus mentions it as the seat of the Alazones and Neuri, who were followed by the Dacians and Getæ. The Romans left traces of their rule in the Wall of Trajan, which stretches through the modern districts of Kamanets, Ushitsa, and Proskuroff. Many nationalities passed through this territory, or settled within it for some time, during the great migrations, leaving traces in numerous archaeological remains. The annals of Nestor mention that the Slavonians, Bujanes, and Dulcebes occupied the Bug, while the Tiverts and Uglitches were settled on the Dniester. They were conquered by the Avars in the 7th century. Oleg extended his rule over this territory—the *Ponizie*, or lowland, which became later a part of the principalities of Volhynia, Kieff, and Galicia. In the 13th century the *Ponizie* was plundered by the Mongols; a hundred years afterwards Olgerd freed it from this rule, annexing it to Lithuania under the name of *Podolia*, a word which has the same meaning as *Ponizie*. After the death of Witowt Podolia was annexed to Poland, with the exception of its eastern part—the province of Bratslaff—

which remained under Lithuania until its union with Poland. The Poles retained Podolia until the third division of Poland in 1793, when it was taken by Russia, which instituted the present government of Podolia in 1796.

PODOLSK, a district-town of Russia, in the government of Moscow, is situated 23 miles to the south of the capital, at the junction of the two main roads going from Moscow to the Crimea and to Warsaw, and within a mile from the Podolsk railway station. It is picturesquely built on the hilly banks of the Pakhra, here crossed by an elegant suspension bridge for carriages as well as by the railway bridge. Down to 1781, when it became a district town, the wealthy village of Podol was a dependency of the Daniloff monastery of Moscow, and it still maintains many of the features of a suburb of that city. The numberless caravans of cars and sledges which before the opening of the southern railway carried on the entire transport of merchandise to and from Moscow (as they still to some extent continue to do) had their chief halting place at Podolsk before setting out on a long journey, or before entering the capital; the principal occupation of the inhabitants was accordingly to keep inns and taverns, and to supply the caravans with provisions and other necessities of travel. The merchants of Podolsk prefer to carry on their trade at Moscow, and in itself the town has no commercial importance. Still, notwithstanding the recent modifications in traffic produced by the railway system, the population of Podolsk (11,000 in 1881) is increasing. The limestone quarries in the neighborhood, at the confluence of the Desna and Pakhra, supply the capital with a good building material, while a steam factory of cement, lime, and bricks employs 900 hands and has an annual production of about £20,000 [\$97,200]. A paper-mill close to Podolsk has an annual production of about £15,000 [\$72,900].

PODOPHYLLIN, a popular remedy which is much used by those who are averse to the employment of calomel and other mercurial preparations, and hence has been called vegetable mercury. The drug, as used in medicine, is obtained from the rhizome of the American mandrake or May apple, *Podophyllum peltatum*, L., an herbaceous perennial belonging to the natural order *Berberidaceæ*, indigenous in woods in Canada and the United States. The plant is about a foot high, bearing two peltate, deeply-divided leaves, which are about five inches in diameter, and bear in the axil a solitary, stalked, white flower about the size and shape of the garden anemone, with six or more petals and twice as many hypogynous stamens. The fruit is ripe in May, and is an oval, yellowish, fleshy berry containing twelve or more arillate seeds. The rhizome, as met with in commerce, occurs in cylindrical pieces two or three inches long and about $\frac{1}{4}$ inch in diameter, of a chocolate or purplish brown color, smooth and slightly enlarged where the juncture of the leafy stem is indicated by a circular scar on the upper and a few broken rootlets on the under side. The odor is heavy and disagreeable, and the taste acrid and bitter.

Podophyllin is a resinous powder obtained by precipitating an alcoholic tincture of the rhizome by means of water acidulated with hydrochloric acid. It varies in color from grayish to bright yellow or greenish brown, the first-named being the purest. The drug has been the subject of numerous chemical investigations, the most recent of which (Podwysotszki, in *Ztschr. f. Russland*, xx. 777) indicates that its activity is due to a definite resinous compound which has been named by its discoverer *podophyllotoxin*; another constituent named *podophylloquercetin* has neither emetic nor purgative properties, but appears to be the cause of the griping pains which sometimes accompany the action of podophyllin; a third substance, *podophyllic acid* has no medicinal action. *Podophyllotoxin* is a bitter amorphous principle soluble in weak alcohol and in hot water, ether, and chloroform, but insoluble in petroleum spirit. It is split up by the action of alkalis into a resin-acid named *picropodophyllic acid*, which is inert, and a very active substance, *picropodophyllin*, which crystallizes in delicate silky needles. *Picropodophyllin* is insoluble in water, and almost insoluble in spirit of less than 80 per cent., but is

rendered soluble when united to the *picropodophyllic acid*. *Podophylloquercetin* crystallizes in short needles of a yellow color and metallic lustre. It is soluble in ether and alcohol, and forms a compound with acetate of lead which is soluble in acetic acid and can be sublimed in shining yellow crystals, and which on exposure to the air gradually becomes green. *Podophyllic acid* is insoluble in water and in ether, but soluble in alcohol. In medicine podophyllin is employed for torpor of the liver and obstinate constipation, arising from sedentary employment, imprudence in diet, and irregularity of habits. In small doses it acts as a slow and gentle laxative, especially if combined with henbane and belladonna, but in large doses it is an irritant hydragogue cathartic, the action of which persists for some time. The usual dose as a laxative and mild hepatic stimulant is about $\frac{1}{4}$ of a grain, but the samples met with in commerce vary considerably in strength, and act with varying effect upon different individuals. Specimens having a greenish tint should be avoided, since they probably contain podophylloquercetin and tend to cause severe griping. In large doses it appears to lose its stimulant action on the liver. Podophyllin is official in the pharmacopœias of Great Britain, India, France, Russia, and the United States.

POE, EDGAR ALLAN (1809-1849), is the most interesting figure in American literature, and his life furnishes the most extraordinary instance on record of systematic misrepresentation on the part of a biographer. The greater part of his short working life was passed in intense and unremitting literary toil, and no poems or romances were ever produced at greater expense of brain and spirit than his. Yet, till lately, when Mr. J. H. Ingram, the careful editor of Poe's works, undertook to collect the plain facts of the poet's life, the current statement and belief were that his strange tales and poems were flung off from a disordered imagination in the intervals of degraded debauchery. This myth was studiously floated by his first biographer, Griswold, and found readier acceptance with the public owing to the weird and horrible character of much of his imaginative work. Griswold's story of a life wayward and irregular from hapless beginning to disgraceful close was just what people were prepared to believe about a genius so eccentric and with such a turn for dark mysteries, horrible crimes, inhuman doings and sufferings. That the author of such works should have been expelled from the university and from the army, and from situation after situation when he tried to make a living by literature, all owing to the gross irregularity of his habits, and should finally have died in a hospital in a fit of intoxication, seemed credible enough when affirmed by a self-constituted biographer. Many of Griswold's allegations were denied at the time, but the denials were local and isolated, and the truth had no chance against the systematic libel, repeated as it was in many editions, till Mr. Ingram prepared a regular and authoritative memoir.¹

There was a sufficient mixture of truth with falsehood to make Griswold's story plausible. It was not quite correct to describe Poe as the son of strolling players, but his father, a man of good family, had married an actress and taken to the stage as a profession. Their son was born in Baltimore, February 19, 1809,² and father and mother died in 1811 when he was a child. The orphan was adopted by his godfather, Mr. Allan, a wealthy merchant, and from his eighth till his thirteenth year (1816-1821) was placed at school in England. Thence he was transferred to an academy at Richmond, Virginia, and thence at the age of seventeen to the university of Virginia at Charlottesville. Mr. Allan was childless, and apparently treated his adopted son as his own child. Why Poe left the university after one session is not clearly explained, but it has been ascertained that he was not expelled, but on the contrary was honorably distinguished as a student, although it is admitted that he

¹ See his *Works of Edgar Allan Poe*, 4 vols., 1874-75.

² [R. H. Stoddard's edition of Poe's *Poems*, N. Y., 1875, gives Boston as the place of the poet's birth, as does Woodberry's *Life*, Boston, 1885.—AM. ED.]

had contracted debts and had "an ungovernable passion for card-playing." These debts may have been sufficient cause for a quarrel with Mr. Allan. Poe disappeared for two years, setting out for Europe to join the Greeks in their fight for independence. Reappearing at Richmond in 1829, he stayed at home for a year, and then was entered as a military cadet at West Point. But all his ambitions by this time were towards literature; he neglected his duties, disobeyed orders, and was dismissed from the service of the United States. What he did for two years after is not ascertained, but in 1833 he reappeared as the successful competitor for a prize offered by a Baltimore newspaper for a prose story. From that time he subsisted by literature. Mr. Allan had married again, and died soon afterwards, leaving an heir by his second wife, and "not a mill," as Griswold puts it, to Poe.

It is chiefly in his account of Poe's literary career that Griswold has been guilty of slandering the subject of his biography, representing him as rendered incapable of permanent employment by his intemperate habits. There would seem to be not the slightest foundation for this coarse slander. During the fifteen years of his literary life Poe was connected with various newspapers and magazines in Richmond, New York, and Philadelphia, and there is unanimous testimony that so far from being an irregular contributor, he was a model of punctuality and thoroughness, and took a pride in these homely virtues. His connection was not in any one case "severed by his irregularities." He wrote first for the *Southern Literary Messenger* in Richmond, and edited it for some time; then in 1837, he removed to New York, and wrote criticisms and did editorial work for the *New York Quarterly Review*; then, after a year, with a prospect of more lucrative employment, he removed to Philadelphia, and for four years was the mainstay of *Graham's Magazine*. His literary work was poorly paid for, though some of his most powerful tales—*Hans Pfaal*, *Arthur Gordon Pym*, *Ligeia*, *The House of Usher*, *The Murders in the Rue Morgue*, *Marie Roget*, *The Descent into the Maelström*—were among Poe's contributions to these periodicals. Not unnaturally he conceived the idea of starting a magazine of his own as the most hopeful way of living by his work, but he had no capital and was obliged to abandon the project and return to New York and miscellaneous journalism. To add to his troubles, his wife, a cousin of his own, whom he had married in 1836 and to whom he was passionately attached, was in very delicate health, and during a lingering illness of eight years gave him constant anxiety. We have only to look at the character of Poe's work and the condition of such literature commercially, to see why it was that the most popular writer of his generation in America had to struggle so hard for a bare subsistence. His short stories were an easy prey for the newspaper pirate, and when thousands were reading them the author received nothing but the few dollars paid him by the publication in which they first appeared. The *Raven* was published first in 1845, and in a few months was being read and recited and parodied wherever the English language was spoken; but the half-starved poet, who had to live by his genius, received only two pounds for the production. And, fertile and active as his imagination was, these short works of his, which served for the passing sensation of the newspaper reader, were far from being extempore effusions. His *Philosophy of Composition* is sometimes, indeed generally, regarded as half serious half a jest in the author's peculiar way of mystification. But to any one who examines Poe's work closely by the light of this essay it is obvious that the disclosure of his method is only too seriously true. It would have been well for his own powers of endurance if he had composed on a less exacting and exhausting system. The most fantastic of Poe's creations are not the product of the imagination abandoned to the impulses of a dominant mood; the effects are

deliberately calculated, as he says they were, step by step and point by point to a prearranged culmination. A man writing on such a system, with the wolf at the door and affections daily on the rack, could hardly have endured the strain if he had had a constitution of iron. It was no wonder that Poe's health became distempered, or that, during the last years of his wife's illness and the two remaining years through which he survived her, he had recourse to the dangerous help of stimulants. Not only did he subject his imagination to exhausting conditions, but he wasted his force in doing with superfluous thoroughness what a ready journalist would have dismissed with a few easy sentences of commonplace. When we read his criticisms, which are full of insight and suggestion, we see that in reviewing a book or a poem he was never satisfied till he had thought out what could be done with the subject. His famous feat in anticipating the plot of *Barnaby Rudge* from the opening chapters was only a sample of the thoroughness with which he threw himself into whatever he undertook. Poe failed to make a living by literature, not because he was an irregular profligate in the vulgar sense, but because he did ten times as much work as he was paid to do—a species of profligacy, perhaps, but not quite the same in kind as that with which he was charged by his malignant biographer.

The current story about his breaking off his engagement with Mrs. Whitman by presenting himself at her house in a state of violent drunkenness has been proved to be a fabrication, and many other stories about him have been exploded by Mr. Ingram. His wife died in 1847 and he followed her in 1849, dying under painful circumstances at Baltimore. For a critical estimate of Poe's writings the reader may be referred to Professor Nichol's *American Literature*. There are few English writers of this century whose fame is likely to be more enduring. The feelings to which he appeals are simple but universal, and he appeals to them with a force that has never been surpassed. (W. M.)

POERIO, CARLO (1803–1867), Italian statesman, born in 1803, was descended from an old Calabrian family and was the son of Giuseppe Poerio, a distinguished lawyer of Naples. In 1815 he accompanied his father into political exile, but, a pardon having been obtained in 1818, he returned to Naples where he afterwards adopted the profession of advocate. From 1837 to 1848 he was frequently arrested and imprisoned, but, when Ferdinand, moved by the demonstration of 27th January of the latter year, promulgated a constitution, he was at once raised to honor, being made prefect of police and shortly afterwards minister of public instruction. Discovering, however, that the king was only temporizing, he resigned office in April of the same year and was returned for Naples to Parliament, where he led the constitutional opposition. On 19th July, 1849, he was arrested and, after trial on the charge of belonging to the sect denominated the "Italian Unity," was condemned to irons. Chained in pairs, he and other fifteen political prisoners were confined in one small room in the bagna of Nisida near the lazaretto. The eloquent exposure of the horrors of the Neapolitan dungeons by Mr. Gladstone in 1851, who emphasized especially the case of Poerio, awakened the universal indignation of Europe, but he did not obtain his liberty till 1858. He and other exiles were then placed on board a ship bound for the United States, but they compelled the crew to land them at Cork, whence Poerio made his way to London. In the following year he returned to Italy, and in 1860 he was elected deputy to the parliament of Turin, of which he was chosen vice-president in 1861. He died at Florence, 28th April, 1867.

POETRY.

IN modern criticism the word poetry is used sometimes to denote any expression (artistic or other) of imaginative feeling, sometimes to designate one of the fine arts.

As an expression of imaginative feeling, as the movement of an energy, as one of those great primal human forces which go the development of the race, poetry in the wide sense has played as important a part as science. In some literatures (such as that of England) poetic energy and in others (such as that of Rome) poetic art is the dominant quality. It is the same with individual writers. In classical literature Pindar may perhaps be taken as a type of the poets of energy; Virgil of the poets of art. With all his wealth of poetic art Pindar's mastery over symmetrical methods never taught him to "sow with the hand," as Corinna declared, while his poetic energy always impelled him to "sow with the whole sack." In English poetical literature Elizabeth Barrett Browning typifies, perhaps, the poets of energy; while Keats (notwithstanding all his unquestionable inspiration) is mostly taken as a type of the poets of art. In French literature Hugo, notwithstanding all his mastery over poetic methods, represents the poets of energy.

In some writers, and these the very greatest—in Homer, Æschylus, Sophocles, Dante, Shakespeare, Milton and perhaps Goethe—poetic energy and poetic art are seen in something like equipoise. It is of poetry as an art, however, that we have mainly to speak here; and all we have to say upon poetry as an energy is that the critic who, like Aristotle, takes this wide view of poetry—the critic who, like him, recognizes the importance of poetry in its relations to man's other expressions of spiritual force, claims a place in point of true critical sagacity above that of a critic who, like Plato, fails to recognize that importance. And assuredly no philosophy of history can be other than inadequate should it ignore the fact that poetry has had as much effect upon human destiny as that other great human energy by aid of which, from the discovery of the use of fire to that of the electric light, the useful arts have been developed.

With regard to poetry as an art, in the present work most of the great poems of the world have been or will be examined either in connection with the names of the writers or with the various literatures to which they belong; consequently these remarks must be confined to general principles. To treat historically so vast a subject as poetry, would be obviously impossible here.

All that can be attempted is to inquire briefly—(1)

What is poetry? (2) What is the position it takes up in relation to the other arts? (3) What is its value and degree of expressional power in relation to these? and, finally, (4) What varieties of poetic art are the outcome of the two great kinds of poetic impulse, dramatic imagination and lyric or egoistic imagination?

1. *What is Poetry?*—Definitions are for the most part alike unsatisfactory and treacherous; but definitions of poetry are proverbially so. Is it possible to lay down invariable principles of poetry, such as those famous "invariable principles" of the Rev. Mr. Bowles, which in the earlier part of the century awoke the admiration of Southey and the wrath of Byron? Is it possible for a critic to say of any metrical phrase, stanza, or verse, "This is poetry," or "This is not poetry"? Can he, with anything like the authority with which the man of science pronounces upon the natural objects brought before him pronounce upon the qualities of a poem? These are questions that have engaged the attention of critics ever since the time of Aristotle.

Byron, in his rough and ready way, has answered

them in one of those letters to the late John Murray, which, rich as they are in nonsense, are almost as rich in sense. "So far are principles of poetry from being invariable," says he, "that they never were nor ever will be settled. These principles mean nothing more than the predilections of a particular age, and every age has its own and a different from its predecessor. It is now Homer and now Virgil; once Dryden and since Sir Walter Scott; now Corneille and now Racine; now Cr billon and now Voltaire." This is putting the case very strongly—perhaps too strongly. But if we remember that Sophocles lost the first prize for the * dipus Tyrannus*; if we remember what in Dante's time (owing partly, no doubt, to the universal ignorance of Greek) were the relative positions of Homer and Virgil, what in the time of Milton were the relative positions of Milton himself, of Shakespeare, and of Beaumont and Fletcher; again, if we remember Jeffrey's famous classification of the poets of his day, we shall be driven to pause over Byron's words before dismissing them. Yet some definition, for the purpose of this essay, must be here attempted; and, using the phrase "absolute poetry" as the musical critics use the phrase "absolute music," we may, perhaps, without too great presumption submit the following:

Absolute poetry is the concrete and artistic expression of the human mind in emotional and rhythmical language.

Absolute poetry defined.

This at least will be granted, that no literary expression can properly speaking be called poetry that is not in a certain deep sense emotional, whatever may be its subject matter, concrete in its method, and its diction, rhythmical in movement, and artistic in form.

That the expression of all real poetry must be concrete in method and diction is obvious, and yet this dictum would exclude from the definition much of what is called didactic poetry. With abstractions the poet has nothing to do, save to take them and turn them into concretions; for, as artist, he is simply the man who by instinct embodies in concrete forms that "universal idea" which Gravina speaks of—that which is essential and elemental in nature and in man; as poetic artist he is simply the man who by instinct chooses for his concrete forms metrical language. And the questions to be asked concerning any work of art are simply these—

It is concrete in method.

Is that which is here embodied really permanent, universal, and elemental? and Is the concrete form embodying it really beautiful—acknowledged as beautiful by the soul of man in its highest moods? Any other question is an impertinence.

Examples are always useful in discussions such as this.

As an example of the absence of concrete form in verse take the following lines from George Eliot's *Spanish Gypsy*:

"Speech is but broken light upon the depth
Of the unspoken; even your loved words
Float in the larger meaning of your voice
As something dimmer."

Without discussing the question of blank verse cadence and the weakness of a line where the main accent falls upon a positive hiatus, "of the unspoken," we would point out that this powerful passage shows the spirit of poetry without its concrete form. The abstract method is substituted for the concrete. Such an abstract phrase as "the unspoken" belongs entirely to prose.

As to what is called ratiocinative poetry, it might perhaps be shown that it does not exist at all. Not by syllogism, but *per saltum*, must the poet reach in

Poetry as an energy and as an art.

Divisions of the subject.

What is poetry.

every case his conclusions. We listen to the poet—we allow him to address us in rhythm or in rhyme—we allow him to sing to us while other men are only allowed to talk, not because he argues more logically than they, but because he feels more deeply and perhaps more truly. It is for his listeners to be knowing and ratiocinative; it is for him to be gnomic and divinely wise.

That poetry must be metrical or even rhythmical in movement, however, is what some have denied. Here we touch at once the very root of the subject. The difference between all literature and mere "word-kneading" is that, while literature is alive, word-kneading is without life. This literary life, while it is only bipartite in prose, seems to be tripartite in poetry; that is to say, while prose requires intellectual life and emotional life, poetry seems to require not only intellectual life and emotional life but rhythmic life, this last being the most important of all according to many critics, though Aristotle is not among these. Here indeed is the "fork" between the old critics and the new. Unless the rhythm of any metrical passage is so vigorous, so natural, and so free that it seems as though it could live, if need were, by its rhythm alone, has that passage any right to exist? and should it not, if the substance is good, be forthwith demetricalized and turned into prose? Thoreau has affirmed that prose, at its best, has high qualities of its own beyond the ken of poetry; to compensate for the sacrifice of these, should not the metrical gains of any passage be beyond all cavil?

But this argument might be pressed further still. It might seem bold to assert that, in many cases, the mental value of poetry may actually depend upon form and color, but would it not be true? The mental value of poetry must be judged by a standard not applicable to prose; but, even with regard to the different kinds of poetry, we must not compare poetry whose mental value consists in a distinct and logical enunciation of ideas, such as that of Lucretius and Wordsworth, and poetry whose mental value consists partly in the suggestive richness of passion or symbol latent in rhythm (such as that of Sappho sometimes,

Pindar often, Shelley always), or latent in color, such as that of some of the Persian poets. To discuss the question, Which of these two kinds of poetry is the more precious? would be idle, but are we not driven to admit that certain poems whose strength is rhythm, and certain other poems whose strength is color, while devoid of any logical statement of thought, may be as fruitful of thoughts and emotions too deep for words as a shaken prism is fruitful of tinted lights? The mental forces at work in the production of a poem like the *Excursion* are of a very different kind from the mental forces at work in the production of a poem like Shelley's "Ode to the West Wind." In the one case the poet's artistic methods, like those of the Greek architect, show, and are intended to show, the solid strength of the structure. In the other, the poet's artistic methods, like those of the Arabian architect, contradict the idea of solid strength—make the structure appear to hang over our heads like the cloud pageantry of heaven. But, in both cases, the solid strength is, and must be, there, at the base. Before the poet begins to write he should ask himself which of these artistic methods is natural to him; he should ask himself whether his natural impulse is towards the weighty iambic movement whose primary function is to state, or towards those lighter movements which we still call, for want of more convenient words, anapaestic and dactylic, whose primary function is to suggest. Whenever Wordsworth and Keats pass from the former to the latter they pass at once into doggerel. Nor is it difficult to see why English anapaestic and dactylic verse must suggest and not state, as even so comparatively successful a *tour de force* as Shelley's

"Sensitive Plant" shows. Conciseness is a primary virtue of all statement. The moment the English poet tries to "pack" his anapaestic or dactylic line, as he can pack his iambic line, his versification becomes rugged, harsh, pebbly—becomes so of necessity. Nor is this all: anapaestic and dactylic verse must in English be obtrusively alliterative, or the same pebbly effect begins to be felt. The anapaestic line is so full of syllables that in a language where the consonants dominate the vowels (as in English), these syllables grate against each other, unless their corners are artfully bevelled by one of the only two smoothing processes at the command of an English versifier—obtrusive alliteration, or an obtrusive use of liquids. Now these demands of form may be turned by the perfect artist to good account if his appeal to the listener's soul is primarily that of suggestion by sound or symbol, but if his appeal is that of direct and logical statement the diffuseness inseparable from good anapaestic and dactylic verse is a source of weakness such as the true artist should find intolerable.

But enough has been said to show that in discussing poetry questions of versification touch, as we have said, the very root of the subject.

Using the word "form" in a wider sense still, a sense that includes "composition," it can be shown that poetry to be entitled to the name must be artistic in form. Whether a poem be a Welsh *triban* or a *stornello* improvised by an Italian peasant girl, whether it be an ode by Keats or a tragedy by Sophocles, it is equally a work of art. The artist's command over form may be shown in the peasant girl's power of spontaneously rendering in simple verse, in her *stornello* or *rispetto*, her emotions through nature's symbols; it may be shown by Keats in that perfect fusion of all poetic elements of which he was such a master, in the manipulation of language so beautiful both for form and color that thought and words seem but one blended loveliness; or it may be shown by Sophocles in a mastery over what in painting is called composition, in the exercise of that wise vision of the artist which, looking before and after, sees the thing of beauty as a whole, and enables him to grasp the eternal laws of cause and effect in art and bend them to his own wizard will. In every case, indeed, form is an essential part of poetry; and, although George Sand's saying that "*L'art est une forme*" applies perhaps more strictly to the plastic arts (where the soul is reached partly through mechanical means), its application to poetry can hardly be exaggerated.

Owing, however, to the fact that the word *ποιητής* (first used to designate the poetic artist by Herodotus) means maker, Aristotle seems to have assumed that the indispensable basis of poetry is invention. He appears to have thought that a poet is a poet more on account of the composition of the action than on account of the composition of his verses. Indeed he said as much as this. Of epic poetry he declared emphatically that it produces its imitations either by mere articulate words or by metre superadded. This is to widen the definition of poetry so as to include all imaginative literature, and Plato seems to have given an equally wide meaning to the word *ποίησις*. Only, while Aristotle considered *ποίησις* to be an imitation of the facts of nature, Plato considered it to be an imitation of the dreams of man. Aristotle ignored, and Plato slighted, the importance of versification (though Plato on one occasion admitted that he who did not know rhythm could be called neither musician nor poet). It is impossible to discuss here the question whether an imaginative work in which the method is entirely concrete and the expression entirely emotional, while the form is unmetrical, is or is not entitled to be called a poem. That there may be a kind of unmetrical narrative so poetic in motive, so concrete in diction, so emotional in treatment, as to escape altogether from those critical canons usually

It is rhythmic in movement.

It is artistic in form.

Importance of metrical questions.

applied to prose, we shall see when, in discussing the epic, we come to touch upon the Northern sagas.

Perhaps the first critic who tacitly revolted against the dictum that substance, and not form, is the indispensable basis of poetry was Dionysius of Halicarnassus, whose treatise upon the arrangement of words is really a very fine piece of literary criticism. In his acute remarks upon the arrangement of the words in the sixteenth book of the *Odyssey*, as compared with that in the story of Gyges by Herodotus, was perhaps first enunciated clearly the doctrine that poetry is fundamentally a matter of style. The Aristotelian theory as to invention, however, dominated all criticism after as well as before Dionysius. When Bacon came to discuss the subject (and afterwards) the only division between the poetical critics was perhaps between the followers of Aristotle and those of Plato as to what poetry should, and what it should not, imitate. It is curious to speculate as to what would have been the result had the poets followed the critics in this matter. Had not the instinct of the poet been too strong for the schools, would poetry as an art have been lost and merged in such imaginative prose as Plato's? Or is not the instinct for form too strong to be stifled? By the poets themselves metre was always considered to be the one indispensable requisite of a poem, though, as regards criticism, so recently as the time of the appearance of the *Waverley Novels*, the *Quarterly Review* would sometimes speak of them as "poems"; and perhaps even now there are critics of a very high rank who would do the same with regard to romances so concrete in method and diction, and so full of poetic energy, as *Wuthering Heights* and *Jane Eyre*, where we get absolutely all that Aristotle requires for a poem. On the whole, however, the theory that versification is not an indispensable requisite of a poem seems to have become nearly obsolete in our time. Perhaps, indeed, many critics would now go so far in the contrary direction as to say with Hegel (*Aesthetik*, iii. p. 289) that "metre is the first and only condition absolutely demanded by poetry, yea even more necessary than a figurative picturesque diction." At all events this at least may be said that in our own time the division between poetical critics is not between Aristotelians and Baconians; it is now of a different kind altogether. While one group of critics may still perhaps say with Dryden that "a poet is a maker, as the name signifies," and that "he who cannot make, that is, invent, has his name for nothing," another group contends that it is not the invention but the artistic treatment, the form, which determines whether an imaginative writer is a poet or a writer of prose,—contends, in short, that emotion is the basis of all true poetic expression, whatever be the subject matter, that thoughts must be expressed in an emotional manner before they can be brought into poetry, and that this emotive expression demands even yet something else, viz., style and form.

But, although many critics are now agreed that "L'art est une forme," that without metre and without form there can be no poetry, there are few who would contend that poetry can exist by virtue of any one of these alone, or even by virtue of all these combined. Quite independent of verbal melody, though mostly accompanying it, and quite independent of "composition," there is an atmosphere floating around the poet through which he sees everything, an atmosphere which stamps his utterances as poetry; for instance, among all the versifiers contemporary with Donne there was none so rugged as he occasionally was, and yet such songs as "Sweetest love, I do not go for weariness of thee," prove how true a poet he was whenever he could master those technicalities which far inferior poets find comparatively easy. While rhythm may to a very considerable degree be acquired (though, of course, the highest rhythmical effects never can), the power of looking at the world through the atmosphere that floats before the poet's eyes is not to be learned and not to be

taught. This atmosphere is what we call *poetic imagination*, a subject which will have to be fully discussed further on. But first it seems necessary to say a word or two upon that high temper of the soul which in truly great poetry gives birth to this poetic imagination.

The "message" of poetry must be more unequivocal, more thoroughly accentuated, than that of any of the other fine arts. With regard to modern poetry, indeed, it may almost be said that if any writer's verse embodies a message, true, direct, and pathetic, we in modern Europe cannot stay to inquire too curiously about the degree of artistic perfection with which it is delivered, for Wordsworth's saying "That which comes from the heart goes to the heart" applies very closely indeed to modern poetry. The most truly passionate poet in Greece was no doubt in a deep sense the most artistic poet; but in her case art and passion were one, and that is why she has been so cruelly misunderstood. The most truly passionate nature, and perhaps the greatest soul, that in our time has expressed itself in English verse is Elizabeth Barrett Browning; at least it is certain that, with the single exception of Hood in the "Song of the Shirt," no writer of the century has really touched our hearts with a hand so powerful as hers,—and this notwithstanding violations of poetic form, notwithstanding defective rhymes, such as would appal some of the contemporary versifiers of England and France "who lisp in numbers for the numbers [and nothing else] come." The truth is that in order to produce poetry the soul must for the time being have reached that state of exaltation, that state of freedom from self-consciousness, depicted in the lines—

"I started once, or seemed to start, in pain,
Resolved on noble things, and strove to speak,
As when a great thought strikes along the brain,
And flushes all the cheek."

Whatsoever may be the poet's "knowledge of his art," into this mood he must always pass before he can write a truly poetic line. For, notwithstanding all that we have said and are going to say upon poetry as a fine art, it is in the deepest sense of the word an "inspiration" indeed. No man can write a line of genuine poetry without having been "born again" (or, as the true rendering of the text says, "born from above"); and then the mastery over those highest reaches of form which are beyond the ken of the mere versifier comes to him as a result of the change. Hence, with all Mrs. Browning's metrical blemishes, the splendor of her metrical triumphs at her best.

For what is the deep distinction between poet and prose-man? A writer may be many things besides a poet; he may be a warrior like Æschylus, a man of business like Shakespeare, a courtier like Chaucer, or a cosmopolitan philosopher like Goethe; but the moment the poetic mood is upon him all the trappings of the world with which for years he may perhaps have been clothing his soul—the world's knowingness, its cynicism, its self-seeking, its ambition—fall away, and the man becomes an inspired child again, with ears attuned to nothing but the whispers of those spirits from the Golden Age, who, according to Hesiod, haunt and bless the degenerate earth. What such a man produces may greatly delight and astonish his readers, yet not so greatly as it delights and astonishes himself. His passages of pathos draw no tears so deep or so sweet as those that fall from his own eyes while he writes; his sublime passages overawe no soul so imperiously as his own; his humor draws no laughter so rich or so deep as that stirred within his own breast.

It might almost be said, indeed, that Sincerity and Conscience, the two angels that bring to the poet the wonders of the poetic dream, bring him also the deepest, truest delight of form. It might almost be said that by aid of sincerity and conscience the poet is enabled to see more clearly than other men the eternal limits of his own art—to

The poetic temper.

The poetic atmosphere.

Sincerity and conscience.

see with Sophocles that nothing, not even poetry itself, is of any worth to man, invested as he is by the whole army of evil, unless it is in the deepest and highest sense good, unless it comes linking us all together by closer bonds of sympathy and pity, strengthening us to fight the foes with whom fate and even nature, the mother who bore us, sometimes seem in league—to see with Milton that the high quality of man's soul which in English is expressed by the word virtue is greater than even the great poem he prized, greater than all the rhythms of all the tongues that have been spoken since Babel—and to see with Shakespeare and with Shelley that the high passion which in English is called love is lovelier than all art, lovelier than all the marble Mercuries that “await the chisel of the sculptor” in all the marble hills. So much for our first inquiry—“What is poetry?”

2. *What Position does Poetry take up in Relation to the other Arts?*—Notwithstanding the labors of

Lessing and his followers, the position accorded by criticism to poetry in relation to the other arts was never so uncertain and anomalous as at the present moment. On the one hand there is a class of critics who, judging from their perpetual comparison of poems to pictures, claim her as a sort of handmaid of painting and sculpture. On the other hand the disciples of Wagner, while professing to do homage to poetry, claim her as the handmaid of music. To find her proper place is therefore the most important task the critic can undertake at this time, though it is one far beyond the scope of a paper so brief as this. With regard to the relations of poetry to painting and sculpture, however, it seems necessary to glance for a moment at the saying of Simonides, as recorded by Plutarch, that poetry is a speaking picture and that painting is a mute poetry. It appears to have had upon modern criticism as much influence since the publication of Lessing's *Laocoon* as it had before. Perhaps it is in some measure answerable for the modern vice of excessive word-painting. Beyond this one saying, there is little or nothing in Greek literature to show that the Greeks recognized between poetry and the plastic and pictorial arts an affinity closer than that which exists between poetry and music and dancing. Understanding artistic methods more profoundly than the moderns, and far too profoundly to suppose that there is any special and peculiar affinity between an art whose medium of expression is marble and an art whose medium of expression is a growth of oral symbols, the Greeks seem to have studied poetry not so much in its relation to painting and sculpture as in its relation to music and dancing. It is matter of familiar knowledge, for instance, that at the Dionysian festival it was to the poet as “teacher of the chorus” (χοροδιδάκαλος) that the prize was awarded, even though the “teacher of the chorus” were Æschylus himself or Sophocles. And this recognition of the relation of poetry to music is perhaps one of the many causes of the superiority of Greek to all other poetry in adapting artistic means to artistic ends. In Greek poetry, even in Homer's description of the shield of Achilles, even in the famous description by Sophocles of his native woods in the *Edipus Coloneus*, such word-painting as occurs seems, if not inevitable and unconscious, so alive with imaginative feeling as to become part and parcel of the dramatic or lyric movement itself. And whenever description is so introduced the reader of Greek poetry need not be told that the scenery itself rises before the listener's imagination with a clearness of outline and a vigor of color such as no amount of detailed word-painting in the modern fashion can achieve. The picture even in the glorious verses at the end of the eighth book of the *Iliad* rises before our eyes—seems actually to act upon our bodily senses—simply because the poet's eagerness to use the picture for merely illustrating the

solemnity and importance of his story leads to the picture that very authenticity which the work of the modern word-painter lacks.

That the true place of poetry lies between music on the one hand and prose, or loosened speech, on the other, was, we say, taken for granted by the one people in whom the artistic instinct was fully developed.

No doubt they used the word music in a very wide sense, in a sense that might include several arts. But it is a suggestive fact that, in the Greek language, long before poetic art was called “making” it was called “singing.” The poet was not ποιητής but αὐδός. And as regards the Romans it is curious to see how every now and then the old idea that poetry is singing rather than making will disclose itself. It will be remembered, for instance, how Terence, in the prologue of *Phormio*, alludes to poets as musicians. That the ancients were right in this we should be able to show did our scheme permit an historical treatment of poetry; we should be able to show that music and the lyrical function of the poet began together, but that here, as in other things, the progress of art from the implicit to the explicit has separated the two. Every art has its special function, has a certain work which it can do better than any one of its sister arts. Hence its right of existence. For instance, before the “sea of emotion” within the soul has become “curdled into thoughts,” it can be expressed in inarticulate tone. Hence, among the fine arts, music is specially adapted for rendering it. It was perhaps a perception of this fact which made the Syrian Gnostics define life to be “moving music.” When this sea of emotion has “curdled into thoughts,” articulate language rhythmically arranged—words steeped in music and color, but at the same time embodying ideas—can do what no mere wordless music is able to achieve in giving it expression, just as unrhythmical language, language mortised in a foundation of logic, that is to say prose, can best express these ideas as soon as they have cooled and settled and cleared themselves of emotion altogether. Yet every art can in some degree invade the domain of her sisters, and the nearer these sisters stand to each other the more easily and completely can this invasion be accomplished. Prose, for instance, can sometimes, as in the case of Plato, do some of the work of poetry (however imperfectly, and however trammelled by heavy conditions); and sometimes poetry, as in Pindar's odes and the waves of the Greek chorus, can do, though in the same imperfect way, the work of music. The poems of Sappho, however, are perhaps the best case in point. Here the poet's passion is expressed so completely by the mere sound of her verses that a good recitation of them to a person ignorant of Greek would convey something of that passion to the listener; and similar examples almost as felicitous might be culled from Homer, from Æschylus, and from Sophocles. Nor is this power confined to the Greek poets. The students of Virgil have often and with justice commented on such lines as *Æn.* v. 481 (where the sudden sinking of a stricken ox is rendered by means of rhythm), and such lines as *Georg.* ii. 441, where, by means of verbal sounds, the gusts of wind about a tree are rendered as completely as though the voice were that of the wind itself. In the case of Sappho the effect is produced by the intensity of her passion, in the case of Homer by the intensity of the dramatic vision, in the case of Virgil by a supreme poetic art. But it can also be produced by the mere ingenuity of the artist, as in Edgar Poe's “*Ulalume*.” The poet's object in that remarkable *tour de force* was to express dull and hopeless gloom in the same way that the mere musician would have expressed it,—that is to say, by monotonous reiterations, by hollow and dreadful reverberations of gloomy sounds—though as an artist whose vehicle was articulate speech he was obliged to add gloomy ideas, in order to give to his work the intellectual coherence necessary for its existence as a poem. He evidently

The position of poetry in relation to the other arts.

Relation of poetry to music.

set out to do this, and he did it, and "Ulalume" properly intoned would produce something like the same effect upon a listener knowing no word of English that it produces upon us.

On the other hand, music can trench very far upon the domain of articulate speech, as we perceive in the wonderful instrumentation of Wagner. Yet, while it can be shown that the place of poetry is scarcely so close to sculpture and painting as to music on the one side and loosened speech on the other, the affinity of poetry to music must not be exaggerated. We must be cautious how we follow the canons of Wagner and the more enthusiastic of his disciples, who almost seem to think that inarticulate tone can not only suggest ideas but express them—can give voice to the *Verstand*, in short, as well as to the *Vernunft* of man. Even the Greeks drew a fundamental distinction between melic poetry (poetry written to be sung) and poetry that was written to be recited. It is a pity that, while modern critics of poetry have understood or at least have given attention to painting and sculpture, so few have possessed any knowledge of music—a fact which makes Dante's treatise *De Vulgari Eloquentia* so important. Dante was a musician, and seems to have had a considerable knowledge of the relations between musical and metrical laws. But he did not, we think, assume that these laws are identical.

If it is indeed possible to establish the identity of musical and metrical laws, it can only be done by a purely scientific investigation; it can only be done by a most searching inquiry into the subtle relations that we know must exist throughout the universe between all the laws of undulation. And it is curious to remember that some of the greatest masters of verbal melody have had no knowledge of music, while some have not even shown any love of it. All Greek boys were taught music, but whether Pindar's unusual musical skill was born of natural instinct and inevitable passion, or came from the accidental circumstance that his father was, as has been alleged, a musician, and that he was as a boy elaborately taught musical science by Lasus of Hermione, we have no means of knowing. Nor can we now learn how much of Milton's musical knowledge resulted from a like exceptional "environment," or from the fact that his father was a musician. But when we find that Shelley seems to have been without the real passion for music, that Rossetti disliked it, and that Coleridge's apprehension of musical effects was of the ordinary nebulous kind, we must hesitate before accepting the theory of Wagner.

The question cannot be pursued here; but if it should on inquiry be found that, although poetry is more closely related to music than to any of the other arts, yet the power over verbal melody at its very highest is so all-sufficing to its possessor as in the case of Shelley and Coleridge that absolute music becomes a superfluity, this would only be another illustration of that intense egoism and concentration of force—the impulse of all high artistic energy—which is required in order to achieve the rarest miracles of art.

With regard to the relation of poetry to prose, Coleridge once asserted in conversation that the real antithesis of poetry was not prose but science. And if he was right the difference in kind lies, not between the poet and the prose writer, but between the literary artist (the man whose instinct is to manipulate language) and the man of facts and of action whose instinct impels him to act, or, if not to act, to inquire.

One thing is at least certain, that prose, however fervid and emotional it may become, must always be directed, or seem to be directed, by the reins of logic. Or, to vary the metaphor, like a captive balloon it can never really leave the earth.

Indeed, with the literature of knowledge as opposed to the literature of power poetry has nothing to do. Facts have no place in poetry until they are brought

into relation with the human soul. But a mere catalogue of ships may become poetical if it tends to show the strength and pride and glory of the warriors who invested Troy; a detailed description of the designs upon a shield, however beautiful and poetical in itself, becomes still more so if it tends to show the skill of the divine artificer and the invincible splendor of a hero like Achilles. But mere dry exactitude of imitation is not for poetry but for loosened speech. Hence, most of the so-called poetry of Hesiod is not poetry at all. The Muses who spoke to him about "truth" on Mount Helicon made the common mistake of confounding fact with truth. And here we touch upon a very important matter. The reason why in prose speech is loosened is that, untrammelled by the laws of metre, language is able with more exactitude to imitate nature, though of course speech, even when "loosened," cannot, when actual sensible objects are to be depicted compete in any real degree with the plastic arts in accuracy of imitation, for the simple reason that its media are not colors nor solids but symbols—arbitrary symbols which can be made to indicate, but never to reproduce, colors and solids. Accuracy of imitation is the first requisite of prose. But the moment language has to be governed by the laws of metre—the moment the conflict begins between the claims of verbal music and the claims of color and form—then prosaic accuracy has to yield; sharpness of outline, mere fidelity of imitation, such as is within the compass of prose, have in some degree to be sacrificed. But, just as with regard to the relations between poetry and music, the greatest master is he who borrows the most that can be borrowed from music, and loses the least that can be lost from metre, so with regard to the relations between poetry and prose the greatest master is he who borrows the most that can be borrowed from prose and loses the least that can be lost from verse. No doubt this is what every poet tries to do by instinct; but some sacrifice on either side there must be, and, with regard to poetry and prose, modern poets at least might be divided into those who make picturesqueness yield to verbal melody, and those who make verbal melody yield to picturesqueness.

With one class of poets, fine as is perhaps the melody, it is made subservient to outline or to color; with the other class color and outline both yield to metre. The chief aim of the first class is to paint a picture: the chief aim of the second is to sing a song. Weber, in driving through a beautiful country, could only enjoy its beauty by translating it into music. The same may be said of some poets with regard to verbal melody. The supreme artist, however, is he whose pictorial and musical power are so interfused that each seems born of the other, as is the case with Sappho, Homer, Æschylus, Sophocles, and indeed most of the great Greek poets. Among our own poets, (leaving the two supreme masters undiscussed) Keats and Coleridge have certainly done this. The color seems born of the music and the music born of the color. In French poetry the same triumph has been achieved in Victor Hugo's magnificent poem "*En Marchant la Nuit dans un Bois*," which, as a rendering through verbal music of the witchery of nature, stands alone in the poetry of France. For there the poet conquers that crowning difficulty we have been alluding to, the difficulty of stealing from prose as much distinctness of color and clearness of outline as can be imported into verse with as little sacrifice as possible of melody.

But to return to the general relations of poetry to prose. If poetry can in some degree invade the domain of prose, so on the other hand prose can at times invade the domain of poetry, and no doubt the prose of Plato—what is called poetical prose—is a legitimate form of art. Poetry, the earliest form of literature, is also the final and ideal form of all pure literature; and, when Landor insists that poetry and poetical prose are antagonistic, we must remember

Relation
of poetry
to prose.

Coleridge once asserted in conversation that the real antithesis of poetry was not prose but science. And if he was right the difference in kind lies, not between the poet and the prose writer, but between the literary artist (the man whose instinct is to manipulate language) and the man of facts and of action whose instinct impels him to act, or, if not to act, to inquire.

that Lander's judgments are mostly based on feeling, and that his hatred of Plato would be quite sufficient basis with him for an entire system of criticism upon poetical prose. As with Carlyle, there was a time in his life when Plato (who of course is the great figure standing between the two arts of metre and loosened speech) had serious thoughts of becoming a poet. And perhaps, like Carlyle, having the good sense to see his true function, he himself desisted from writing, and strictly forbade other men to write, in verse. If we consider this, and if we consider that certain of the great English masters of poetic prose in the 17th century were as incapable of writing in metre as their followers Richter and Carlyle, we shall hardly escape the conclusion on the one hand that the faculty of writing poetry is quite another faculty than that of producing work in the arts most closely allied to it, music and prose, but that on the other hand there is nothing antagonistic between these faculties. So much for poetry's mere place among the other arts.

Importance of Poetry in Relation to other Arts.—As to the comparative importance and value of poetry among the other arts, this is a subject upon which much discussion, of a more or less idle kind has been wasted. We do not feel called to dwell at any length upon it here. Yet a word or two upon the question is necessary in order that we may understand what is the scope and what are the limits of poetry with regard to the other arts, especially with regard to music and to prose.

There is one great point of superiority that musical art exhibits over metrical art. This consists, not in the capacity for melody, but in the capacity for harmony in the musician's sense. The finest music of Æschylus, of Pindar, of Shakespeare, of Milton, is after all only a succession of melodious notes, and, in endeavoring to catch the harmonic intent of strophe, antistrophe, and epode in the Greek chorus and in the true ode (that of Pindar), we can only succeed by pressing memory into our service. We have to recall by memory the waves that have gone before, and then to imagine their harmonic power in relation to the waves at present occupying the ear. Counterpoint, therefore, is not to be achieved by the metricist, even though he be Pindar himself; but in music this perfect ideal harmony was foreshadowed perhaps in the earliest writing. We know at least that as early as the 12th century counterpoint began to show a vigorous life, and the study of it is now a familiar branch of musical science. Now, inasmuch as "Nature's own hymn" is and must be the harmonic blending of apparently independent and apparently discordant notes, among the arts whose appeal is through the ear that which can achieve counterpoint must perhaps rank as a pure art above one which cannot achieve it. We are of course speaking here of metre only. We have not time to inquire whether the counterpoint of absolute poetry is the harmony underlying apparently discordant emotions—the emotion produced by a word being more persistent than the emotion produced by an inarticulate sound.

But if poetry falls behind music in rhythmic scope, it is capable of rendering emotion after emotion has become disintegrated into thoughts, and here, as we have seen, it enters into direct competition with the art of prose. It can use the emphasis of sound, not for its own sake merely, but to strengthen the emphasis of sense, and can thus give a fuller and more adequate expression to the soul of man than music at its highest can give. With regard to prose, no doubt such writing as Plato's description of the chariot of the soul, his description of the island of Atlantis, or of Er's visit to the place of departed souls, comes but a short way behind poetry in imaginative and even in rhythmic appeal. It is impossible, however, here to do more than touch upon the subject of the rhythm of prose in its relation to the

rhythm of poetry for in this matter the genius of each individual language has to be taken into account.

Perhaps it may be said that deeper than all the rhythms of art is that rhythm which art would fain catch, the rhythm of nature; for the rhythm of nature is the rhythm of life itself. This rhythm can be caught by prose as well as by poetry, such prose, for instance, as that of the English Bible. Certainly the rhythm of verse at its highest, such, for instance, as that of Shakespeare's greatest writings, is nothing more and nothing less than the metre of that energy of the spirit which surges within the bosom of him who speaks, whether he speak in verse or in impassioned prose. Being rhythm, it is of course governed by law, but it is a law which transcends in subtlety the conscious art of the metricist, and is only caught by the poet in his most inspired moods, a law which, being part of nature's own sanctions, can of course never be formulated but only expressed, as it is expressed in the melody of the bird, in the inscrutable harmony of the entire bird-chorus of a thicket, in the whisper of the leaves of the tree, and in the song or wail of wind and sea. Now is not this rhythm of nature represented by that "sense of rhythm" which prose can catch as well as poetry, that sense of rhythm whose finest expressions are to be found in the Bible, Hebrew and English, and in the Biblical movements of the English Prayer Book, and in the dramatic prose of Shakespeare at its best? Whether it is caught by prose or by verse, one of the virtues of the rhythm of nature is that it is translatable. Hamlet's peroration about man and Raleigh's apostrophe to death are as translatable into other languages as are the Hebrew psalms, or as is Manu's magnificent passage about the singleness of man (we quote from memory):

"Single is each man born into the world; single he dies; single he receives the reward of his good deeds, and single the punishment of his evil deeds. When he dies his body lies like a fallen tree upon the earth, but his virtue accompanies his soul. Wherefore let man harvest and garner virtue, so that he may have an inseparable companion in traversing that gloom which is so hard to be traversed."

Here the rhythm, being the inevitable movement of emotion and "sense," can be caught and translated by every literature under the sun. While, however, the great goal before the poet is to compel the listener to expect his caesuric effects, the great goal before the writer of poetic prose is in the very opposite direction; it is to make use of the concrete figures and impassioned diction of the poet, but at the same time to avoid the recognized and expected metrical bars upon which the poet depends. The moment the prose poet passes from the rhythm of prose to the rhythm of metre the apparent sincerity of his writing is destroyed.

And now how stands poetry with regard to the plastic arts? This is in truth a vast subject, and has given birth to an infinitude of eloquent criticism in the present century. It cannot be expected that we should be able to discuss it adequately here. Yet this, too, must be glanced at. On the one side poetry is inferior to the plastic arts; on another side it is superior to them.

As compared with sculpture and painting the great infirmity of poetry, as an "imitation" of nature, is of course that the medium is always and of necessity words—even when no words could, in the dramatic situation, have been spoken. It is not only Homer who is obliged sometimes to forget that passion when at white heat is never voluble, is scarcely even articulate; the dramatists also are obliged to forget that in love and in hate, at their tensest, words seem weak and foolish when compared with the silent and satisfying triumph and glory of deeds, such as the plastic arts can render. This becomes manifest enough when we compare the Niobe group or the Laocoon group, or the great dramatic paintings of the modern world, with even the finest efforts of dramatic poetry, such as the speech of Andromache to Hector, or the

Importance of poetry in relation to other arts.

Where poetry is inferior and where superior to music;

to plastic art.

speech of Priam to Achilles, nay such as even the cries of Cassandra in the *Agamemnon*, or the wailings of Lear over the dead Cordelia. Even when writing the words uttered by *Œdipus*, as the terrible truth breaks in upon his soul, Sophocles must have felt that, in the holiest chambers of sorrow and in the highest agonies of suffering reigns that awful silence which not poetry, but painting sometimes, and sculpture always, can render. What human sounds could render the agony of Niobe, or the agony of Laocœon, as we see them in the sculptor's rendering? Not articulate speech at all; not words but wails. It is the same with hate; it is the same with love. We are not speaking merely of the unpacking of the heart in which the angry warriors of the *Iliad* indulge. Even such subtle writing as that of *Æschylus* and Sophocles falls below the work of the painter. Hate, though voluble perhaps, as Clytæmnestra's when hate is at that red-heat glow which the poet can render, changes in a moment whenever that redness has been fanned to hatred's own last complexion—whiteness as of iron at the melting-point,—when the heart has grown far too big to be "unpacked" at all, and even the bitter epigrams of hate's own rhetoric, though brief as the terrier's snap before he fleashes his teeth, or as the short snarl of the tigress as she springs before her cubs in danger, are all too slow and sluggish for a soul to which language at its tensest has become idle play. But this is just what cannot be rendered by an art whose medium consists solely of words.

It is in giving voice, not to emotion at its tensest, but to the variations of emotion, it is in expressing the countless shifting movements of the soul from passion to passion, that poetry shows in spite of all her infirmities her superiority to the plastic arts. *Hamlet* and the *Agamemnon*, the *Iliad* and the *Œdipus Tyrannus*, are adequate to the entire breadth and depth of man's soul.

Poetic Imagination.—We have now reached our last general inquiry—What varieties of poetic art are the outcome of the two kinds of poetic impulse, dramatic imagination and lyric or egoistic imagination? It would of course be impossible within the space at our command to examine fully the subject of poetic imagination. For in order to do so we should have to enter upon the vast question of the effect of artistic environment upon the development of man's poetic imagination; we should have to inquire how the instinctive methods of each poet and of each group of poets have been modified and often governed by the methods characteristic of their own time and country. We should have to inquire, for instance, how far such landscape as that of Sophocles in the *Œdipus Coloneus* and such landscape as that of Wordsworth depends upon difference of individual temperament, and how far upon difference of artistic environment. That, in any thorough and exhaustive discussion of poetic imagination, the question of artistic environment must be taken into account, the case of the *Iliad* is alone sufficient to show—a case that will at once occur to the reader. Ages before Phrynicus, ages before an acted drama was dreamed of, a dramatic poet of the first order arose, and, though he was obliged to express his splendid dramatic imagination through epic forms, he expressed it almost as fully as if he had inherited the method and the stage of Sophocles. And if Homer never lived at all, then an entire group of dramatic poets arose in remote times whose method was epic instead of dramatic simply because there was then no stage.

This, contrasted with the fact that in a single half-century the tragic art of Greece arose with *Æschylus*, culminated with Sophocles, and decayed with Euripides, and contrasted also with the fact that in England at one time, and in Spain at one time, almost the entire poetic imagination of the country found expression in the acted drama alone, is sufficient to show that

a poet's artistic methods are very largely influenced by the artistic environments of his country and time. So vast a subject as this, however, is, as we say, quite beyond the scope of any essay like this, and we can only point to the familiar instance of the troubadours and the trouvères and then pass on.

With the trouvère (the poet of the *langue d'oïl*), the story or situation is always the end of which the musical language is the means; with the troubadour (the poet of the *langue d'oc*), the form is so beloved, the musical language so enthralling, that, however beautiful may be the story or situation, it is felt to be no more than the means to a more beloved and beautiful end. But then nature makes her own troubadours and her own trouvères irrespective of fashion and of time—irrespective of *langue d'oc* and *langue d'oïl*. And, in comparing the troubadours with the trouvères, this is what strikes us at once—there are certain troubadours who by temperament, by original endowment of nature, ought to have been trouvères, and there are certain trouvères who by temperament ought to have been troubadours. Surrounding conditions alone have made them what they are. There are those whose impulse (though writing in obedience to contemporary fashions lyrics in the *langue d'oc*) is manifestly to narrate, and there are those whose impulse (though writing in obedience to contemporary fashions *fabliaux* in the *langue d'oïl*) is simply to sing. In other words, there are those who, though writing after the fashion of their brother troubadours, are more impressed with the romance and wonderfulness of the human life outside them than with the romance and wonderfulness of their own passions, and who delight in depicting the external world in any form that may be the popular form of their time; and there are those who, though writing after the fashion of their brother trouvères, are far more occupied with the life within them than with that outer life which the taste of their time and country calls upon them to paint—born rhythmists who must sing, who translate everything external as well as internal into verbal melody. Of the former class Pierre Vidal, of the latter class the author of "Le Lay de l'Oiselet," may be taken as the respective types.

That the same forces are seen at work in all literatures few students of poetry will deny,—though in some poetical groups these forces are no doubt more potent than in others, as, for instance, with the great parable poets of Persia, in some of whom there is perpetually apparent a conflict between the dominance of the Oriental taste for allegory and subtle suggestion, as expressed in the Zoroastrian definition of poetry,—“apparent pictures of unapparent realities,”—and the opposite yearning to represent human life with the freshness and natural freedom characteristic of Western poetry.

Allowing, however, for all the potency of external influences, we shall not be wrong in saying that of poetic imagination there are two distinct kinds—(1) the kind of poetic imagination seen at its highest in *Æschylus*, Sophocles, Shakespeare, and Homer, and (2) the kind of poetic imagination seen at its highest in Pindar, Dante, and Milton, or being in Sappho, Heine, and Shelley. The former, or else in its highest dramatic exercise unconditioned by the personal or lyrical impulse of the poet, might perhaps be called absolute dramatic vision; the latter, being more or less conditioned by the personal or lyrical impulse of the poet, might be called relative dramatic vision. It seems impossible to classify poets, or to classify the different varieties of poetry, without drawing some such distinction as this, whatever words of definition we may choose to adopt.

For the achievement of all pure lyric poetry, such as the ode, the song, the elegy, the idyl, the sonnet, the stornello, it is evident that the imaginative force we have called relative vision will suffice. And if we con-

Poetic imagination.

Artistic environment.

All poetry the outcome of absolute vision or of relative vision.

sider the matter thoroughly, in many other forms of poetic art—forms which at first sight might seem to require absolute vision—we shall find nothing but relative vision at work.

Even in Dante, and even in Milton and Virgil, it might be difficult to trace the working of any other than relative vision. And as to the entire body of Asiatic poets it might perhaps be found (even in view of the Indian drama) that relative vision suffices to do all their work. Indeed the temper which produces true drama is, it might almost be said, a growth of the Western mind. For, unless it be Semitic as seen in the dramatic narratives of the Bible, or Chinese as seen in that remarkable prose story, *The Two Fair Cousins*, translated by Rémusat, absolute vision seems to have but small place in the literatures of Asia. The wonderfulness of the world and the romantic possibilities of fate, or circumstance, or chance—not the wonderfulness of the character to whom these possibilities befall—are ever present to the mind of the Asiatic poet. Even in so late a writer as the poet of the *Shāh Nāmah*, the hero Irij, the hero Zal, and the hero Zohreb are in character the same person, the virtuous young man who combines the courage of youth with the wisdom and forbearance of age. And, as regards the earlier poets of Asia, it was not till the shadowy demigods and heroes of the Asiatic races crossed the Caucasus, and breathed a more bracing air, that they became really individual characters. But among the many qualities of man's mind that were invigorated and rejuvenated by that great exodus from the dreamy plains of Asia is to be counted, above all others, his poetic imagination. The mere sense of wonder, which had formerly been an all-sufficing source of pleasure to him, was all-sufficing no longer. The wonderful adventure must now be connected with a real and interesting individual character. It was left for the poets of Europe to show that, given the interesting character, given the Achilles, the Odysseus, the Helen, the Priam, any adventure happening to such a character becomes interesting.

What then is this absolute vision, this true dramatic imagination which can hardly be found in Asia—which even in Europe cannot be found except in rare cases? Between relative and absolute vision the difference seems to be this, that the former only enables the poet, even in its very highest exercise, to make his own individuality, or else humanity as represented by his own individuality, live in the imagined situation; the latter enables him in its highest exercise to make special individual characters other than the poet's own live in the imagined situation.

"That which exists in nature," says Hegel, "is a something purely individual and particular. Art on the contrary is essentially destined to manifest the general." And no doubt this is true as regards the plastic arts, and true also as regards literary art, save in the very highest reaches of pure drama and pure lyric, when it seems to become art no longer—when it seems to become the very voice of Nature herself. The cry of Priam when he puts to his lips the hand that slew his son is not merely the cry of a bereaved and aged parent; it is the cry of the individual king of Troy, and expresses above everything else that most naïf, pathetic, and winsome character. Put the words into the mouth of the irascible and passionate Lear and they would be entirely out of keeping.

It may be said then that, while the poet of relative vision, even in its very highest exercise, can only, when depicting the external world, deal with the general, the poet of absolute vision can compete with Nature herself and deal with both general and particular. Now if this is really so we may perhaps find a basis for a classification of poetry and of poets. That all poets must be singers has already been maintained. But singers seem to be divisible into three classes: first the pure lyrists, each of whom can with his one voice sing only one tune; secondly the epic poets, save

Homer, the bulk of the narrative poets, and the quasi-dramatists, each of whom can with his one voice sing several tunes; and thirdly the true dramatists, who, having, like the nightingale of Gongora, many tongues, can sing all tunes.

It is to the first-named of these classes that most poets belong. With regard to the second class, there are not of course many poets left for it: the first absorbs so many. But, when we come to consider that among those who, with each his one voice, can sing many tunes, are Pindar, Firdausi, Jami, Virgil, Dante, Milton, Spenser, Goethe, Byron, Coleridge, Shelley, Keats, Schiller, Victor Hugo, the second class is so various that no generalization save such a broad one as ours could embrace its members. And now we come to class three, and must pause. The third class is necessarily very small. It can only be placed such names as Shakespeare, Æschylus, Sophocles, Homer, and (hardly) Chaucer.

These three kinds of poets represent three totally different kinds of poetic activity.

With regard to the first, the pure lyrists, the impulse is pure egoism. Many of them have less of even relative vision at its highest than the mass of mankind. They are often too much engaged with the emotions within to have any deep sympathy with the life around them. Of every poet of this class it may be said that his mind to him "a kingdom is," and that the smaller the poet the bigger to him is that kingdom. To make use of a homely image—like the chaffinch whose eyes have been pricked by the bird-fancier, the pure lyrist is sometimes a warbler because he is blind. Still he feels that the Muse loves him exceedingly. She takes away his eyesight, but she gives him sweet song. And his song is very sweet, very sad, and very beautiful; but it is all about the world within his own soul—its sorrows, joys, fears, and aspirations.

With regard to the second class the impulse here is no doubt a kind of egoism too; yet the poets of this class are all of a different temper from the pure lyrists. They have a wide imagination; but it is still relative, still egoistic. They have splendid eyes, but eyes that never get beyond seeing general, universal humanity (typified by themselves) in the imagined situation. Not even to these is it given to break through that law of centrality by which every "me" feels itself to be the central "me"—the only "me" of the universe, round which all other spurious "mes" revolve. This "me" of theirs they can transmute into many shapes, but they cannot create other "mes,"—nay, for egoism, some of them scarcely would perhaps if they could.

The third class, the true dramatists, whose impulse is the simple yearning to create akin to that which made "the great Vishnu yearn to create a world," are "of imagination all compact,"—so much so that when at work "the divinity" which Iamblichus speaks of "seizes for the time the soul and guides it as he will."

The distinction between the pure lyrists and the other two classes of poets is obvious enough. But the distinction between the quasi-dramatists and the pure dramatists requires a word of explanation before we proceed to touch upon the various kinds of poetry that spring from the exercise of relative and absolute vision. Sometimes, to be sure, the vision of the true dramatists—the greatest dramatists—will suddenly become narrowed and obscured, as in that part of the *Œdipus Tyrannus* where Sophocles makes Œdipus ignorant of what every one in Thebes must have known, the murder of Laius. And again, finely as Sophocles has conceived the character of Electra, he makes her, in her dispute with Chrysothemis, give expression to sentiments that, in another play of his own, come far more appropriately from the lofty character of Antigone in a parallel dispute with Ismene. And, on the other hand, examples of relative vision, in its furthest reaches, can be found in abundance everywhere, especially in Virgil, Dante, Calderon, and Milton; but in

TENNYSON (P. KRAMER)

our limited space we can give but two or three. Some of the most remarkable examples of that high kind of relative vision which may easily be mistaken for absolute vision may be found in those great prose epics of the North which Aristotle would have called poems. Here is one from the *Völsunga Saga*. While the brothers of Gudrun are about their treacherous business of murdering Sigurd, her husband, as he lies asleep in her arms, Brynhild, Sigurd's former love, who in the frenzy of "love turned to hate" has instigated the murderers to the deed, hovers outside the chamber with Gunnar, her husband, and listens to the wail of her rival who is weltering in Sigurd's blood. At the sound of that wail Brynhild laughs—

"Then said Gunnar to her, Thou laughest not because thy heart roots are gladdened, or else why doth thy visage wax so wan?"¹

This is of course very fine; but, as any two characters in that dramatic situation might have done that dramatic business, fine as it is,—as the sagaman gives us the general and not the particular,—the vision at work is not absolute but relative at its very highest exercise. But our examples will be more interesting if taken from English poets. In Coleridge's "Ancient Mariner" we find an immense amount of relative vision of so high a kind that at first it seems absolute vision. When the ancient mariner, in his narrative to the wedding guest, reaches the slaying of the albatross, he stops, he can proceed no further, and the wedding guest exclaims—

"God save thee, Ancient Mariner,
From the fiends that plague thee thus!
Why look'st thou so?" "With my cross-bow
I shot the albatross."

But there are instances of relative vision—especially in the great master of absolute vision, Shakespeare—which are higher still,—so high indeed that not to relegate them to absolute vision seems at first sight pedantic. Such an example is the famous speech of Lady Macbeth in the second act, where she says—

"Had he not resembled
My father as he slept, I had done 't."

Marvellously subtle as is the speech, it will be found, if analyzed, that it expresses the general human soul rather than any one special human soul. Indeed Leigh Hunt records the case of a bargeman who, charged with robbing a sleeping traveller in his barge, used in his confession almost identical words—"Had he not looked like my father as he slept, I should have killed as well as robbed him." Again, the thousand and one cases (to be found in every literature) where a character, overwhelmed by some sudden surprise or terror, asks whether the action going on is that of a dream or of real life, must all, on severe analysis, be classed under relative rather than under absolute vision,—even such a fine speech, for instance, as that where Pericles, on discovering Marina, exclaims—

"This is the rarest dream that e'er dull sleep
Did mock sad fools withal;"

or as that in the third act of *Titus Andronicus*, where Titus, beholding his mutilated and ruined daughter, asks—

"When will this fearful slumber have an end?"

even here, we say, the humanity rendered is general and not particular, the vision at work is relative and not absolute. The poet, as representing the whole human race, throwing himself into the imagined situation, gives us what general humanity would have thought, felt, said, or done in that situation, not what one particular individual and he alone would have thought, felt, said, or done.

Now what we have called absolute vision operates in a very different way. So vividly is the poet's mere

creative instinct at work that the *ego* sinks into passivity—becomes insensitive to all impressions other than those dictated by the vision—by the "divinity" which has "seized the soul."

We have left ourselves little room for examples; but Shakespeare is full of them.

Take the scene in the first act of *Hamlet* where Hamlet hears for the first time, from Horatio, that his father's ghost haunts the castle. Having by short sharp questions elicited the salient facts attending the apparition, Hamlet says, "I would I had been there." To this Horatio makes the very commonplace reply, "It would have much amazed you." Note the marvellously dramatic reply of Hamlet—"Very like, very like! Stayed it long?" Suppose that this dialogue had been attempted by any other poet than a true dramatist, or by a true dramatist in any other mood than his very highest, Hamlet, on hearing Horatio's commonplace remarks upon phenomena which to Hamlet were more subversive of the very order of the universe than if a dozen stars had fallen from their courses, would have burst out with—"Amazed me!" and then would have followed an eloquent declamation about the "amazing" nature of the phenomena and their effect upon him. But so entirely has the poet become Hamlet, so completely has "the divinity seized his soul," that all language seems equally weak for expressing the turbulence within the soul of the character, and Hamlet exclaims in a sort of meditative irony, "very like, very like!" It is exactly this one man Hamlet, and no other man, who in this situation would have so expressed himself. Charles Knight has some pertinent remarks upon this speech of Hamlet; yet he misses its true value, and treats it from the general rather than from the particular side. Instances of absolute vision in Shakespeare crowd upon us, but we can find room for only one other. In the pathetic speech of Othello, just before he kills himself he declares himself to be—

"One not easily jealous, but, being wrought,
Perplexed in the extreme."

Consider the marvellous *timbre* of the word "wrought," as coming from a character like Othello. When writing this passage, especially when writing this word, the poet had become entirely the simple English soldier-hero, as the Moor really is—he had become Othello, looking upon himself "as not easily jealous," whereas he was "wrought" and "perplexed in the extreme" by tricks which Hamlet would have seen through in a moment.

While all other forms of poetic art can be vitalized by relative vision, there are two forms (and these the greatest) in which absolute vision ^{Where absolute vision is demanded, viz., the drama, and in a lesser degree the Greek epic, especially the} is demanded, viz., the drama, and in a

Iliad. This will be seen more plainly perhaps if we now vary our definitions and call relative vision egoistic imagination, absolute vision dramatic imagination.

Drama has been already fully treated in the present work (see DRAMA). But it follows from what has been here said that very much of the dramatist's work can be, and in fact is, effected by egoistic imagination, while true dramatic imagination is only called into play on comparatively rare occasions. Not only fine but sublime dramatic poems have been written, however, where the vitalizing power has been entirely that of lyrical imagination. We need only instance the *Prometheus Bound* of Æschylus, the most sublime poem in the world. The dramas of Shelley too, like those of Victor Hugo and Calderon, are informed entirely by egoistic imagination. In all these splendid poems the dramatist places himself in the imagined situation, or at most he places there some typical conception of universal humanity. There is not in all Calderon any such display of dramatic imagination as we get in that wonderful speech of Priam's in the last book of the *Iliad* to which we have before alluded.

¹ Translation of Morris and Magnusson.

There is not in the *Cenci* such a display of dramatic imagination as we get in the sudden burst of anger from the spoilt child of gods and men, Achilles (anger which alarms the hero himself as much as it alarms Priam), when the prattle of the old man has carried him too far. It may seem bold to say that the drama of Goethe is informed by egoistic imagination only,—assuredly the prison-scene in *Faust* is unsurpassed in the literatures of the world. Yet, perhaps, it could be shown of the passion and the pathos of Gretchen throughout the entire play that it betrays a female character general and typical rather than individual and particular.

The nature of this absolute vision or true dramatic imagination is easily seen if we compare the dramatic work of writers without absolute vision, such as Calderon, Goethe, Ben Jonson, Fletcher, and others, with the dramatic work of Æschylus and of Shakespeare. While of the former group it may be said that each poet skilfully works his imagination, of Æschylus and Shakespeare it must be said that each in his highest dramatic mood does not work, but is worked by his imagination. Note, for instance, how the character of Clytæmnestra grows and glows under the hand of Æschylus. The poet of the *Odyssey* had distinctly said that Ægisthus, her paramour, had struck the blow, but the dramatist, having imagined the greatest tragic female in all poetry, finds it impossible to let a man like Ægisthus assist such a woman in a homicide so daring and so momentous. And when in that terrible speech of hers she justifies her crime (ostensibly to the outer world but really to her own conscience), the way in which, by the sheer magnetism of irresistible personality, she draws our sympathy to herself and her crime is unrivalled out of Shakespeare and not surpassed even there. In the great drama, in the *Agamemnon*, in *Othello*, in *Hamlet*, in *Macbeth*, there is an imagination at work whose laws are inexorable, are inevitable, as the laws by the operation of which the planets move around the sun. But in this essay our business with drama is confined entirely to its relations to epic.

Considering how large and on the whole how good is the body of modern criticism upon drama, it is surprising how poor is the modern criticism upon epic. Aristotle, comparing tragedy with epic, gives the palm to tragedy as being the more perfect art, and nothing can be more ingenious than the way in which he has marshalled his reasons. He tells us that tragedy as well as epic is capable of producing its effect even without action; we can judge of it perfectly, says he, by reading. He goes so far as to say that, even in reading as well as in representation, tragedy has an advantage over the epic, the advantage of greater clearness and distinctness of impression. And in some measure this was perhaps true of Greek tragedy, for as Müller in his *Dissertations on the Eumenides* has well said, the ancients always remained and wished to remain conscious that the whole was a Dionysian entertainment; the quest of a common-place ἀπάτη came afterwards. And even of Romantic Drama it may be said that in the time of Shakespeare, and indeed down through the 18th century, it never lost entirely its character of a recitation as well as a drama. It was not till melodrama began to be recognized as a legitimate form of dramatic art that the dialogue had to be struck from the dramatic action “at full speed”—struck like sparks from the roadster’s shoes. The truth is, however, that it was idle for Aristotle to inquire which is the more important branch of poetry, epic or tragedy.

Equally idle would it be for the modern critic to inquire how much romantic drama gained and how much it lost by abandoning the chorus. Much has been said as to the scope and the limits of epic and dramatic poetry. If in epic the poet has the power to take the imagination of his audience away from the dramatic centre and show what is going on at the other

end of the great web of the world, he can do the same thing in drama by the chorus, and also by the introduction into the dramatic circle of messengers and others from the outside world.

But, as regards epic poetry, is it right that we should hear, as we sometimes do hear, the voice of the poet himself as chorus bidding us contrast the present picture with other pictures afar off, in order to enforce its teaching and illustrate its pathos? This is a favorite method with modern poets and a still more favorite one with prose narrators. Does it not give an air of self-consciousness to poetry? Does it not disturb the intensity of the poetic vision? Yet it has the sanction of Homer; and who shall dare to challenge the methods of the great father of epic? An instance occurs in *Iliad* v. 158, where, in the midst of all the stress of fight, the poet leaves the dramatic action to tell us what became of the inheritance of Phænops, after his two sons had been slain by Diomedes. Another instance occurs in iii. 243-4, where the poet, after Helen’s pathetic mention of her brothers, comments on the causes of their absence, “criticizes life” in the approved modern way, generalizes upon the impotence of human intelligence—the impotence even of human love—to pierce the darkness in which the web of human fate is woven. Thus she spoke (the poet tells us); but the life-giving earth already possessed them, there in Lacedæmon, in their dear native land:

ὧς φάτο· τοὺς δ’ ἦδ’ ἔπειτα κέλεται φρονὶ ζωὴς αἶα
ἐν Λακεδαίμονι αἰεὶ φίλῃ ἐν πατρίδι γαίῃ.

This of course is “beautiful exceedingly,” but, inasmuch as the imagination at work is egoistic or lyrical, not dramatic, inasmuch as the vision is relative not absolute, it does not represent that epic strength at its very highest which we call specially “Homeric,” unless indeed we remember that with Homer the Muses are omniscient; this certainly may give the passage a deep dramatic value it otherwise seems to lack.

The deepest of all the distinctions between dramatic and epic methods has relation, however, to the nature of the dialogue. Aristotle failed to point it out, and this is remarkable until we remember that his work is but a fragment of a great system of criticism. In epic poetry, and in all poetry that narrates, whether the poet be Homer, Chaucer, Thomas the Rhymer, Gottfried von Strasburg, or Turoldus, the action, of course, moves by aid partly of narrative and partly by aid of dialogue, but in drama the dialogue has a quality of suggestiveness and subtle inference which we do not expect to find in any other poetic form save perhaps that of the purely dramatic ballad. In ancient drama this quality of suggestiveness and subtle inference is seen not only in the dialogue, but in the choral odes. The third ode of the *Agamemnon* is an extreme case in point, where, by a kind of *double entendre*, the relations of Clytæmnestra and Ægisthus are darkly alluded to under cover of allusions to Paris and Helen. Of this dramatic subtlety Sophocles is perhaps the greatest master; and certain critics have been led to speak as though irony were heart-thought of Sophoclean drama. But the suggestiveness of Sophocles is pathetic (as Prof. Lewis Campbell has well pointed out) not ironical. This is one reason why drama more than epic seems to satisfy the mere intellect of the reader, though this may be counterbalanced by the hardness of mechanical structure which sometimes disturbs the reader’s imagination in tragedy.

When, for instance, a dramatist pays so much attention to the evolution of the plot as Sophocles does, it is inevitable that his characters should be more or less plot-ridden; they have to say and do now and then certain things which they would not say and do but for the exigencies of the plot. Indeed one of the advantages which epic certainly has over drama is that the story can be made to move as rapidly as the poet

Epic and
drama
com-
pared.

may desire without these mechanical modifications of character.

The only kind of epic for Aristotle to consider was Greek epic, between which and all other epic the difference is one of kind, if the *Iliad* alone is taken to represent Greek epic. In speaking of the effect that

Place of the
Iliad in epic
poetry.

surrounding conditions seem to have upon the form in which the poetic energy of any time or country should express itself, we instanced the *Iliad* as a typical case. The imagination vivifying it is mainly dramatic. The characters represent much more than the mere variety of mood of the delineator. Notwithstanding all the splendid works of Calderon, Marlowe, Webster, and Goethe, it is doubtful whether as a born dramatist the poet of the *Iliad* does not come nearer to Æschylus and Shakespeare than does any other poet. His passion for making the heroes speak for themselves is almost a fault in the *Iliad* considered as pure epic, and the unconscious way in which each actor is made to depict his own character is in the highest spirit of drama. It is owing to this speciality of the *Iliad* that it stands apart from all other epics save that of the *Odyssey* where, however, the dramatic vision is less vivid. It is owing to the dramatic imagination displayed in the *Iliad* that it is impossible to say, from internal evidence, whether the poem is to be classified with the epics of growth or with the epics of art. All epics are clearly divisible into two classes, first those which are a mere accretion of poems or traditional ballads, and second, those which, though based indeed on tradition or history, have become so fused in the mind of one great poet, so stained, therefore, with the color and temper of that mind, as to become new crystallizations—inventions, in short, as we understand that word. Each kind of epic has excellences peculiar to itself, accompanied by peculiar and indeed necessary defects. In the one we get the freedom—apparently schemeless and motiveless—of nature, but as a consequence, miss that “hard acorn of thought” (to use the picturesque definition in the *Völsunga Saga* of the heart of a man) which the mind asks for as the core of every work of art. In the other this great requisite of an adequate central thought is found, but accompanied by a constriction, a lack of freedom, a cold artificiality, the obtrusion of a pedantic scheme, which would be intolerable to the natural mind unsophisticated by literary study. The flow of the one is as that of a river, the flow of the other as that of a canal. Yet, as has been already hinted, though the great charm of Nature herself is that she never teases us with any obtrusive exhibitions of scheme, she doubtless has a scheme somewhere, she does somewhere hide a “hard acorn of thought” of which the poem of the universe is the expanded expression. And, this being so, art should have a scheme too; but in such a dilemma is she placed in this matter that the epic poet, unless he is evidently telling the story for its own sake, scornful of purposes ethic or æsthetic, must sacrifice illusion.

Among the former class of epics are to be placed the great epics of growth, such as the *Mahābhārata*, the Niblung story, etc.; among the latter the *Odyssey*, the *Æneid*, *Paradise Lost*, the *Jerusalem Liberata*, the *Iliads*.

But where in this classification are we to find a place for the *Iliad*? The heart-thought of the greatest epic in all literature is simply that Achilles was vexed and that the fortunes of the world depended upon the whim of a sulky hero. Yet, notwithstanding all the acute criticisms of Wolff, it remains difficult for us to find a place for the *Iliad* among the epics of growth. And why? Because throughout the *Iliad* the dramatic imagination shown is of the first order; and, if we are to suppose a multiplicity of authors for the poem, we must also suppose that ages before the time of Pericles there existed a group of dramatists more nearly akin to the masters of the

great drama, Æschylus, Sophocles, and Shakespeare than any group that has ever existed since. Yet it is equally difficult to find a place for it amongst the epics of art. In the matter of artistic motive the *Odyssey* stands alone among the epics of art of the world, as we are going to see.

It is manifest that, as the pleasure derived from the epic of art is that of recognizing a conscious scheme, if the epic of art fails through confusion of scheme it fails altogether. What is demanded of the epic of art (as some kind of compensation for that natural freedom of evolution which it can never achieve, that sweet *abandon* which belongs to nature and to the epic of growth alike) is unity of impression, harmonious and symmetrical development of a conscious heart-thought, or motive. This being so, where are we to place the *Æneid* and where are we to place the *Shāh Nāmeḥ*? Starting with the intention, as it seems, of fusing into one harmonious whole the myths and legends upon which the Roman story is based, Virgil, by the time he reaches the middle of his epic, forgets all about this primary intent, and gives us his own thoughts and reflections on things in general. Fine as is the speech of Anchises to Æneas in Elysium (*Æn.* vi. 724-755), its incongruity with the general scheme of the poem as developed in the previous books shows how entirely Virgil lacked that artistic power shown in the *Odyssey* of making a story become the natural and inevitable outcome of an artistic idea.

A conscious
scheme and
motive required
for the true
epic of art.

In the *Shāh Nāmeḥ* there is the artistic redaction of Virgil, but with even less attention to a central thought than Virgil exhibits. Firdausi relies for his effects upon the very qualities which characterize not the epic of art but the epic of growth—a natural and not an artificial flow of the story; so much so indeed that if the *Shāh Nāmeḥ* were studied in connection with the *Iliad* on the one hand and with the *Kalevala* on the other, it might throw a light upon the way in which an epic may be at one and the same time an aggregation of the national ballad poems and the work of a single artificer. That Firdausi was capable of working from a centre not only artistic but philosophic his *Yūsuf and Zuleikha* shows; and if we consider what was the artistic temper of the Persians in Firdausi's time, what indeed has been that temper during the whole of the Mohammedan period, the subtle temper of the parable poet,—the *Shāh Nāmeḥ*, with its direct appeal to popular sympathies, is a standing wonder in poetic literature.

With regard, however, to Virgil's defective power of working from an artistic motive, as compared with the poet of the *Odyssey*, this is an infirmity he shares with all the poets of the Western world. Certainly he shares it with the writer of *Paradise Lost*, who setting out to “justify the ways of God to man,” forgets occasionally the original worker of the evil, as where, for instance, he substitutes chance as soon as he comes (at the end of the second book) to the point upon which the entire epic movement turns, the escape of Satan from hell and his journey to earth for the ruin of man:

“At last his sail-broad vans
He spreads for flight, and, in the surging smoke
Uplifted, spurns the ground; thence many a league,
As in a cloudy chair, ascending rides
Audacious; but, that seat soon failing, meets
A vast vacuity; all unawares,
Fluttering his pinions vain, plumb down he drops
Ten thousand fathoms deep, and to this hour
Down had been falling, had not, by ILL CHANCE,
The strong rebuff of some tumultuous cloud
Instinct with fire and nitre, hurried him
As many miles aloft.”

In Milton's case, however, the truth is that he made the mistake of trying to disturb the motive of a story for artistic purposes—a fatal mistake as we shall see

when we come to speak of the *Nibelungenlied* in relation to the old Norse epic cycle.

Though Vondel's mystery play of *Lucifer* is, in its execution, rhetorical more than poetical, it did, beyond all question, influence Milton when he came to write *Paradise Lost*. The famous line which is generally quoted as the key-note of Satan's character—

"Better to reign in hell than serve in heaven"—

seems to have been taken bodily from Vondel's play, and Milton's entire epic shows a study of it. While Marlowe's majestic movements alone are traceable in Satan's speech (written some years before the rest of *Paradise Lost*, when the dramatic and not the epic form had been selected), Milton's Satan became afterwards a splendid amalgam not of the Mephistopheles but of the *Faustus* of Marlowe and the *Lucifer* of Vondel. Vondel's play must have possessed a peculiar attraction for a poet of Milton's views of human progress. Defective as the play is in execution, it is far otherwise in motive. This motive, if we consider it aright, is nothing less than an explanation of man's anomalous condition on the earth—spirit incarnate in matter, created by God, a little lower than the angels—in order that he may advance by means of these very manacles which imprison him, in order that he may ascend by the staircase of the world, the ladder of fleshly conditions, above those cherubim and seraphim who, lacking the education of sense, have not the knowledge wide and deep which brings man close to God.

Here Milton found his own favorite doctrine of human development and self-education in a concrete and vividly artistic form. Much, however, as such a motive must have struck a man of Milton's instincts, his intellect was too much chained by Calvinism to permit of his treating the subject with Vondel's philosophic breadth. The cause of Lucifer's wrath had to be changed from jealousy of human progress to jealousy of the Son's proclaimed superiority. And the history of poetry shows that once begin to tamper with the central thought around which any group of incidents has crystallized and the entire story becomes thereby re-written, as we have seen in the case of the *Agamemnon* of Æschylus. Of the motive of his own epic, after he had abandoned the motive of Vondel, Milton had as little permanent grasp as Virgil had of his. As regards the *Odyssey*, however, we need scarcely say that its motive is merely artistic, not philosophic. And now we come to philosophic motive.

The artist's power of thought is properly shown not in the direct enunciation of ideas but in mastery over motive. Here Æschylus is by far the greatest figure in Western poetry—a proof perhaps among many proofs of the Oriental strain of his genius. (As regards pure drama, however, important as is motive, freedom, organic vitality in every part, is of more importance than even motive, and in this freedom and easy abandonment the concluding part of the *Oresteia* is deficient as compared with such a play as *Othello* or *Lear*.) Notwithstanding the splendid exception of Æschylus, the truth seems to be that the faculty of developing a poetical narrative from a philosophic thought is Oriental, and on the whole foreign to the genius of the Western mind. Neither in Western drama nor in Western epic do we find, save in such rare cases as that of Vondel, anything like that power of developing a story from an idea which not only Jami but all the parable poets of Persia show.

In recent English poetry, the motive of Shelley's dramatic poem *Prometheus Unbound* is a notable illustration of what is here contended. Starting with the full intent of developing a drama from a motive—starting with a universalism, a belief that good shall be the final goal of ill—Shelley cannot finish his first three hundred lines without shifting (in the curse of

Prometheus) into a Manichæism as pure as that of Manes himself:

"Heap on thy soul, by virtue of this curse,
Ill deeds, then be thou damned, beholding good;
Both infinite as is the universe."

According to the central thought of the poem human nature, through the heroic protest and struggle of the human mind typified by Prometheus, can at last dethrone that supernatural terror and tyranny (Jupiter) which the human mind had itself installed. But, after its dethronement (when human nature becomes infinitely perfectible), how can the supernatural tyranny exist apart from the human mind that imagined it? How can it be as "infinite as the universe"?

The motive of *Paradise Lost* is assailed with much vigor by Victor Hugo in his poem *Religions et Religion*. But when M. Hugo, in the after parts of the poem, having destroyed Milton's "God," sets up an entirely French "Dieu" of his own and tries "to justify" him, we perceive how pardonable was Milton's failure after all. Compare such defect of mental grip and such nebulousity of thought as is displayed by Milton, Shelley, and M. Hugo with the strength of hand shown in the "*Sálámán*" and "*Absal*" of Jami, and indeed by the Sufi poets generally.

There is, however, one exception to this rule that Western poetry is nebulous as to motive. There is, besides the *Iliad*, one epic that refuses to be classified, though for entirely different reasons. That is the Niblung story, where we find unity of purpose and also entire freedom of movement. We find combined here beauties which are nowhere else combined—which are, in fact, at war with each other everywhere else. We find a scheme, a real "acorn of thought," in an epic which is not the self-conscious work of a single poetic artificer, but is as much the slow growth of various times and various minds as is the *Mahābhārata*, in which the heart-thought is merely that the Kauravas defeated their relatives at dice and refused to disgorge their winnings.

This Northern epic-tree, as we find it in the Icelandic sagas, the Norns themselves must have watered; for it combines the virtues of the epic of growth with those of the epic of art. Though not written in metre, it may usefully be compared with the epics of Greece and of India and Persia. Free in movement as the wind, which "bloweth where it listeth," it listeth to move by law. Its action is that of free-will, but free-will at play within a ring of necessity. Within this ring there throbs all the warm and passionate life of the world outside, and all the freedom apparently. Yet from that world it is enisled by a cordon of curses—by a zone of defiant flames more impregnable than that which girdled the beautiful Brynhild at Hindfell. Natural laws, familiar emotions, are at work everywhere in the story; yet the "Ring of Andvari," whose circumference is but that of a woman's finger, encircles the whole mimic world of the sagaman as the Midgard snake encircles the earth. For this artistic perfection in an epic of growth there are, of course, many causes, some of them traceable and some of them beyond all discovery—causes no doubt akin to those which gave birth to many of the beauties of other epics of growth. Originally Sinfliotli and Sigurd were the same person, and note how vast has been the artistic effect of the separation of the two! Again, there were several different versions of the story of Brynhild. The sagamen, finding all these versions too interesting and too much beloved to be discarded, adopted them all—worked them up into one legend, so that, in the *Völsunga Saga* we have a heroine possessing all the charms of goddess, demi-goddess, earthly princess, and amazon—a heroine surpassing perhaps in fascination all other heroines that have ever figured in poetry.

The Great
Northern
Epic.

Philosophic
motive.

It is when we come to consider such imaginative work as this that we are compelled to pause before challenging the Aristotelian doctrine that metrical structure is but an accidental quality of epic; and it will now be seen why, in the early part of this essay, this doctrine was examined so carefully.

In speaking of the Niblung story we do not, of course, speak of the German version, the *Nibelungenlied*, a fine epic still, though a degradation of the elder form. Between the two the differences are fundamental in the artistic sense, and form an excellent illustration of what has just been said upon the disturbance of motive in epic, and indeed in all poetic art. It is not merely that the endings of the three principal characters Sigurd (Siegfried), Gudrun (Kriemhild), and Brynhild are entirely different; it is not merely that the Icelandic version, by missing the blood-bath at Fafnir's lair, loses the pathetic situation of Gudrun's becoming afterwards an unwilling instrument of her husband's death; it is not merely that, on the other hand, the German version, by omitting the early love passages between Brynhild and Sigurd at Hindfell, misses entirely the tragic meaning of her story and the terrible hate that is love resulting from the breaking of the troth; but the conclusion of each version is so exactly the opposite of that of the other that, while the German story is called (and very properly) "*Kriemhild's Revenge*," the story of the *Völsunga Saga* might, with equal propriety, be called Gudrun's Forgiveness.

If it be said that, in both cases, the motive shows the same Titanic temper, that is because the Titanic temper is the special characteristic of the Northwestern mind. The temper of revolt against authority seems indeed to belong to that energy which succeeds in the modern development of the great racial struggle for life. Although no epic, Eastern or Western, can exist without a struggle between good and evil—and a struggle upon apparently equal terms—it must not be supposed that the warring of conflicting forces which is the motive of Eastern epic has much real relation to the warring of conflicting forces which is the motive of Western epic.

And, as regards the machinery of epic, there is, we suspect, a deeper significance than is commonly apprehended in the fact that the Satan or Shaitan of the Eastern world becomes in Vondel and Milton a sublime Titan who attracts to himself the admiration which in Eastern poetry belongs entirely to the authority of heaven. In Asia, save perhaps among the pure Arabs of the desert, underlying all religious forms, there is apparent a temper of resignation to the irresistible authority of heaven. And as regards the Aryans it is probable that the Titanic temper—the temper of revolt against authority—did not begin to show itself till they had moved across the Caucasus. But what concerns us here is the fact that the farther they moved to the northwest the more vigorously this temper asserted itself, the prouder grew man in his attitude towards the gods, till at last in the Scandinavian cycle he became their equal and struggled alongside them, shoulder to shoulder, in the defence of heaven against the assaults of hell. Therefore, as we say, the student of epic poetry must not suppose that there is any real parallel between the attitude of Vishnu (as Rama) towards Ravana and the attitude of Prometheus towards Zeus, or the attitude of the human heroes towards Odin in Scandinavian poetry. Had Ravana been clothed with a properly constituted authority, had he been a legitimate god instead of a demon, the Eastern doctrine of recognition of authority would most likely have come in and the world would have been spared one at least of its enormous epics. Indeed, the Ravana of the *Rāmāyana* answers somewhat to the Fafnir of the *Völsunga Saga*; and to plot against demons is not to rebel against authority. The vast field of Indian epic, however, is quite beyond us here.

Nor can we do more than glance at the *Kalevala*. From one point of view that group of ballads might be taken, no doubt, as a simple record of how the men of Kalevala were skilful in capturing the sisters of the Pohjola men. But from another point of view the universal struggle of the male for the female seems typified in this so-called epic of the Finns by the picture of the "*Lady of the Rainbow*" sitting upon her glowing arc and weaving her golden threads, while the hero is doing battle with the malevolent forces of nature.

But it is in the Niblung story that the temper of Western epic is at its best—the temper of the simple fighter whose business it is to fight. The ideal Western fighter was not known in Greece till ages after Homer, when in the pass of Thermopylæ the companions of Leonidas combed their long hair in the sun. The business of the fighter in Scandinavian epic is to yield to no power whatsoever, whether of earth or heaven or hell—to take a buffet from the Allfather himself, and to return it; to look Destiny herself in the face, crying out for quarter neither to gods nor demons nor Norns. This is the true temper of pure "*heroic poetry*" as it has hitherto flourished on this side the Caucasus—the temper of the fighter who is invincible because he feels that Fate herself falters when the hero of the true strain defies—the fighter who feels that the very Norns themselves must cringe at last before the simple courage of man standing naked and bare of hope against all assaults whether of heaven or hell or doom. The proud heroes of the *Völsunga Saga* utter no moans and shed no Homeric tears, knowing as they know that the day prophesied is sure when, shoulder to shoulder, gods and men shall stand up to fight the entire brood of night and evil, storming the very gates of Asgard.

That this temper is not the highest from the ethical point of view is no doubt true. Against the beautiful resignation of Buddhism it may seem barbaric, and if moral suasion could supplant physical force in epic—if Siddhartha could take the place of Achilles or Sigurd—it might be better for the human race.

But it would be difficult even to glance at the countless points of interest that suggest themselves in connection with epic poetry. Returning now to the general subject of egoistic or lyrical and dramatic imagination,—as might be expected, we occasionally meet imagination of a purely dramatic kind in narrative poetry, such for instance as that of Gottfried von Strassburg, of Chaucer, and of the author of the *Chanson de Roland*.

But we must now give undivided attention to pure egoistic or lyric imagination. This, as has been said, is sufficient to vitalize all forms of poetic art save drama and the Greek epic. Many of these forms have been or will be treated in this work under separate heads.

What forms of poetic art are the natural outcome of egoistic imagination.

It would be impossible to discuss adequately here the Hebrew poets, who have produced a lyric so different in kind from all other lyrics as to stand in a class by itself. As it is equal in importance to the Great Drama of Shakespeare, Æschylus, and Sophocles, we may perhaps be allowed to call it the "*Great Lyric*." The Great Lyric must be religious—it must, it would seem, be an outpouring of the soul, not towards man but towards God, like that of the God-intoxicated prophets and psalmists of Scripture. Even the lyric fire of Pindar owes much to the fact that he had a child-like belief in the myths to which so many of his contemporaries had begun to give a languid assent. But there is nothing in Pindar, or indeed elsewhere in Greek poetry, like the rapturous song, combining unconscious power with unconscious grace, which we have called the Great Lyric. It might perhaps be said indeed that the Great Lyric is purely Hebrew.

But, although we could hardly expect to find it among those whose language, complex of the great lyric of the Hebrews stands alone. syntax and alive with self-conscious inflections, bespeaks the scientific knowingness of the Western mind, to call the temper of the Great Lyric broadly "Asiatic" would be rash. It seems to belong as a birthright to those descendants of Shem who, yearning always to look straight into the face of God and live, could (when the Great Lyric was sung) see not much else.

Though two of the artistic elements of the Great Lyric, unconsciousness and power, are no doubt plentiful enough in India, the element of grace is lacking for the most part. The Vedic hymns are both nebulous and unemotional, as compared with Semitic hymns. And as to the Persians, they, it would seem, have the grace always, the power often, but the unconsciousness almost never. This is inevitable if we consider for a moment the chief characteristic of the Persian imagination—an imagination whose wings are not so much "bright with beauty" as heavy with it—heavy as the wings of a golden pheasant—steeped in beauty like the "tiger-moth's deep damasked wings." Now beauty of this kind does not go to the making of the Great Lyric.

Then there comes that poetry which, being ethnologically Semitic, might be supposed to exhibit something at least of the Hebrew temper—the Arabian. But, whatever may be said of the oldest Arabic poetry, with its deep sense of fate and pain, it would seem that nothing can be more unlike than the Hebrew temper and the Arabian temper as seen in later poets. It is not with Hebrew but with Persian poetry that Arabian poetry can be usefully compared. If the wings of the Persian imagination are heavy with beauty, those of the later Arabian imagination are bright with beauty—brilliant as an Eastern butterfly, quick and agile as a dragon-fly or a humming-bird. To the eye of the Persian poet the hues of earth are (as Firdausi says of the garden of Afrasiab) "like the tapestry of the kings of Ormuz, the air is perfumed with musk, and the waters of the brooks are the essence of roses." And to the later Arabian no less than to the Persian the earth is beautiful; but it is the clear and sparkling beauty of the earth as she "wakes up to life, greeting the Sabæan morning": we feel the light more than the color.

But it is neither the Persian's instinct for beauty nor the Arabian's quenchless wit and exhaustless animal spirits that go to the making of the Great Lyric; far from it. In a word, the Great Lyric, as we have said, cannot be assigned to the Asiatic temper generally any more than it can be assigned to the European temper.

In the poetry of Europe, if we cannot say of Pindar, devout as he is, that he produced the Great Lyric, what can we say of any other European poet? The truth is that like the Great Drama, so straight and so warm does it seem to come from the heart of man in its highest moods that we scarcely feel it to be literature at all. Passing, however, from this supreme expression of lyrical imagination, we come to the artistic

ode, upon which subject the present writer can only reiterate here what he has more fully said upon a former occasion. Whatever may have been said to the contrary, enthusiasm is in the nature of things, the very basis of the ode; for the ode is a mono-drama, the actor in which is the poet himself; and, as Marmontel has well pointed out, if the actor in the mono-drama is not affected by the sentiments he expresses, the ode must be cold and lifeless. But, although the ode is a natural poetic method of the poet considered as prophet—although it is the voice of poetry as a fine frenzy—it must not be supposed that there is anything lawless in its structure. "Pindar," says the Italian critic Gravina, "launches his verses upon the bosom of the sea; he spreads out all his sails; he confronts the tempest and the rocks; the waves arise and are ready to engulf

him; already he has disappeared from the spectator's view; when suddenly he springs up in the midst of the waters, and reaches happily the shore." Now it is this Pindaric discursiveness, this Pindaric unrestraint as to the matter, which has led poets to attempt to imitate him by adopting an unrestraint as to form. Although no two odes of Pindar exhibit the same metrical structure (the Æolian and Lydian rhythms being mingled with the Doric in different proportions), yet each ode is in itself obedient, severely obedient, to structural law. This we feel; but what the law is no metricist has perhaps ever yet been able to explain.

It was a strange misconception that led people for centuries to use the word "Pindaric" and irregular as synonymous terms; whereas the very essence of the odes of Pindar (of the few, alas! which survive to us) is their regularity. There is no more difficult form of poetry than this, and for this reason: when in any poetical composition the metres are varied, there must, as the present writer has before pointed out, be a reason for such freedom, and that reason is properly subjective—the varying form must embody and express the varying emotions of the singer. But when these metrical variations are governed by no subjective law at all, but by arbitrary rules supposed to be evolved from the practice of Pindar, then that very variety which should aid the poet in expressing his emotion crystallizes it and makes the ode the most frigid of all compositions. Great as Pindar undoubtedly is, it is deeply to be regretted that no other poet survives to represent the triumphal ode of Greece,—the digressions of his subject-matter are so wide, and his volubility is so great.

In modern literature the ode has been ruined by theories and experiments. A poet like La Mothe, for instance, writes execrable odes, and then writes a treatise to prove that all odes should be written on the same model. The modern ode.

There is much confusion of mind prevalent among poets as to what is and what is not an ode. All odes are, no doubt, divisible into two great classes: those which, following an arrangement in stanzas, are commonly called regular, and those which, following no such arrangement, are commonly called irregular.

We do not agree with those who assert that irregular metres are of necessity inimical to poetic art. On the contrary, we believe that in modern prosody the arrangement of the rhymes and the length of the lines in any rhymed metrical passage may be determined either by a fixed stanzaic law or by a law infinitely deeper—by the law which impels the soul, in a state of poetic exaltation, to seize hold of every kind of metrical aid, such as rhyme, cæsure, etc., for the purpose of accentuating and marking off each shade of emotion as it arises, regardless of any demands of stanza. But between the irregularity of make-shift, such as we find it in Cowley and his imitators, and the irregularity of the "fine frenzy" of such a poem, for instance, as Coleridge's *Kubla Khan*, there is a difference in kind. Strange that it is not in an ode at all but in this unique lyric *Kubla Khan*, descriptive of imaginative landscape, that an English poet has at last conquered the crowning difficulty of writing in irregular metres. Having broken away from all restraints of couplet and stanza,—having caused his rhymes and pauses to fall just where and just when the emotion demands that they should fall, scorning the exigencies of makeshift no less than the exigencies of stanza,—he has found what every writer of irregular English odes has sought in vain, a music as entrancing, as natural, and at the same time as inscrutable, as the music of the winds or of the sea.

The prearranged effects of sharp contrasts and antipodal movements, such as some poets have been able to compass, do not of course come under the present definition of irregular metres at all. If a metrical passage Stanzaic law and emotional law.

does not gain immensely by being written independently of stanzaic law, it loses immensely; and for this reason, perhaps, that the great charm of the music of all verse, as distinguished from the music of prose, is inevitableness of cadence. In regular metres we enjoy the pleasure of feeling that the rhymes will inevitably fall under a recognized law of couplet or stanza. But if the passage flows independently of these, it must still flow inevitably—it must, in short, show that it is governed by another and a yet deeper force, the inevitableness of emotional expression. The lines must be long or short, the rhymes must be arranged after this or after that interval, not because it is convenient so to arrange them, but because the emotion of the poet inexorably demands these and no other arrangements. When, however, Coleridge came to try his hand at irregular odes, such as the odes “To the Departing Year” and “To the Duchess of Devonshire,” he certainly did not succeed.

As to Wordsworth’s magnificent “Ode on Intimations of Immortality,” the sole impeachment of it, but it is a grave one, is that the length of the lines and the arrangement of the rhymes are not always inevitable; they are, except on rare occasions, governed neither by stanzaic nor by emotional law. For instance, what emotional necessity was there for the following rhyme-arrangement?

“My heart is at your festival,
My head hath its coronal,
The fulness of your bliss I feel—I feel it all.
Oh, evil day! if I were sullen
While earth herself is adorning,
This sweet May morning;
And the children are culling,
On every side,
In a thousand valleys far and wide,
Fresh flowers.”

Beautiful as is the substance of this entire passage, so far from gaining, it loses by rhyme—loses, not in perspicuity, for Wordsworth like all his contemporaries (except Shelley) is mostly perspicuous, but in that metrical emphasis the quest of which is one of the impulses that leads a poet to write in rhyme. In spite, however, of its metrical defects, this famous ode of Wordsworth’s is the finest irregular ode in the language; for, although Coleridge’s “Ode to the Departing Year” excels it in Pindaric fire, it is below Wordsworth’s masterpiece in almost every other quality save rhythm. Among the writers of English irregular odes, next to Wordsworth, stands Dryden. The second stanza of the “Ode for St. Cecilia’s Day” is a great triumph.

Leaving the irregular and turning to the regular ode, it is natural to divide these into two classes: (1) those which are really Pindaric in so far as they consist of strophes, antistrophes, and epodes, variously arranged and contrasted; and (2) those which consist of a regular succession of regular stanzas. Perhaps all Pindaric odes tend to show that this form of art is in English a mistake. It is easy enough to write one stanza and call it a strophe, another in a different movement and call it an antistrophe, a third in a different movement still and call it an epode. But in modern prosody, disconnected as it is from musical and from terpsichorean science, what are these? No poet and no critic can say.

What is requisite is that the ear of the reader should catch a great metrical scheme, of which these three varieties of movement are necessary parts,—should catch, in short, that inevitableness of structure upon which we have already touched. In order to justify a poet in writing a poem in three different kinds of movement, governed by no musical and no terpsichorean necessity, a necessity of another kind should make itself apparent; that is, the metrical wave moving in the strophe should be metrically answered by the

counter-wave moving in the antistrophe, while the epode—which, as originally conceived by Stesichorus, was merely a standing still after the balanced movements of the strophe and antistrophe—should clearly, in a language like ours, be a blended echo of these two. A mere metrical contrast such as some poets labor to effect is not a metrical answer. And if the reply to this criticism be that in Pindar himself no such metrical scheme is apparent, that is the strongest possible argument in support of our position. If indeed the metrical scheme of Pindar is not apparent, that is because, having been written for chanting, it was subordinate to the lost musical scheme of the musician. It has been contended, and is likely enough, that this musical scheme was simple—as simple, perhaps, as the scheme of a cathedral chant; but to it, whatever it was, the metrical scheme of the poet was subordinated. It need scarcely be said that the phrase “metrical scheme” is used here not in the narrow sense as indicating the position and movement of strophe and antistrophe by way of simple contrast, but in the deep metrical sense as indicating the value of each of these component parts of the ode, as a counter-wave balancing and explaining the other waves in the harmony of the entire composition. We touch upon this matter in order to show that the moment odes ceased to be chanted, the words strophe, antistrophe, and epode lost the musical value they had among the Greeks, and pretended to a complex metrical value which their actual metrical structure does not appear to justify. It does not follow from this that odes should not be so arranged, but it does follow that the poet’s arrangement should justify itself by disclosing an entire metrical scheme in place of the musical scheme to which the Greek choral lyric was evidently subordinated. But even if the poet were a sufficiently skilled metrist to compass a scheme embracing a wave, an answering wave, and an echo gathering up the tones of each, i.e., the strophe, the antistrophe, and the epode, the ear of the reader, unaided by the musical emphasis which supported the rhythms of the old choral lyric, is, it should seem, incapable of gathering up and remembering the sounds further than the strophe and the antistrophe, after which it demands not an epode but a return to the strophe. That is to say, an epode, as alternating in the body of the modern ode, is a mistake; a single epode at the end of a group of strophes and antistrophes (as in some of the Greek odes) has, of course, a different function altogether.

The great difficulty of the English ode is that of preventing the apparent spontaneity of the impulse from being marred by the apparent artifice of the form; for, assuredly, no writer subsequent to Coleridge and to Keats would dream of writing an ode on the cold Horatian principles adopted by Wharton, and even by Collins, in his beautiful “Ode to Evening.”

Of the second kind of regular odes, those consisting of a regular succession of regular stanzas, the so-called odes of Sappho are, of course, so transcendent that no other amatory lyrics can be compared with them. Never before these songs were sung and never since did the human soul, in the grip of a fiery passion, utter a cry like hers; and, from the executive point of view, in directness, in lucidity, in that high imperious verbal economy which only nature herself can teach the artist, she has no equal, and none worthy to take the place of second—not even in Heine, not even in Burns. Turning, however, to modern poetry, there are some magnificent examples of this simple form of ode in English poetry—Spenser’s immortal “Epithalamion” leading the way in point of time, and probably also in point of excellence.

Fervor being absolutely essential, we think, to a great English ode, fluidity of metrical movement can never be dispensed with. The more billowy the metrical waves the better suited are they to render the

The true Pindaric ode is regular.

Is it suited to modern poetry?

The simple ode of regular stanzas.

emotions expressed by the ode, as the reader will see by referring to Coleridge's "Ode to France" (the finest ode in the English language, according to Shelley), and giving special attention to the first stanza—to the way in which the first metrical wave, after it had gently fallen at the end of the first quatrain, leaps up again on the double rhymes (which are expressly introduced for this effect), and goes bounding on, billow after billow, to the end of the stanza. Not that this fine ode is quite free from the great vice of the English ode, rhetoric. If we except Spenser and, in one instance, Collins, it can hardly be said that any English writer before Shelley and Keats produced odes independent of rhetoric and supported by pure poetry alone. But fervid as are Shelley's "Ode to the West Wind," and Keats's Odes "To a Nightingale" and "On a Grecian Urn," they are entirely free from rhetorical flavor. Notwithstanding that in the "Ode on a Grecian Urn" the first stanza does not match in rhyme arrangement with the others, while the second stanza of the "Ode to a Nightingale" varies from the rest by running on four rhyme-sounds instead of five, vexing the ear at first by disappointed expectation, these two odes are, after Coleridge's "France," the finest regular odes perhaps in the English language.

With regard to the French ode, Malherbe was the first writer who brought it to perfection. The French ode. Malherbe showed also more variety of mood than it is the fashion just now to credit him with. This may be especially noted in his "Ode to Louis XIII." His disciple Racan is not of much account. There is certainly much vigor in the odes of Rousseau, but it is not till we reach Victor Hugo that we realize what French poetry can achieve in this line; and contemporary poetry can hardly be examined here. We may say, however, that some of Hugo's odes are truly magnificent. As a pure lyricist his place among the greatest poets of the world is very high. Here, though writing in an inferior language, he ranks with the greatest masters of Greece, of England, and of Germany. Had he attempted no other kind of poetry than lyrical, his would still have been the first name in French poetry. Whatever is defective in his work arises, as in the case of Euripides, from the importation of lyrical force where dramatic force is mainly needed.

As most of the other varieties of lyrical poetry, such as the idyl, the satire, the ballad, the sonnet, etc., have been or will be treated under different heads, or under the names of the various masters of poetic art, it would be superfluous to discuss them here.

A word or two, however, must be said about the song and the elegy. To write a good song requires that simplicity of grammatical structure which is foreign to many natures—that mastery over direct and simple speech which only true passion and feeling can give, and which "coming from the heart goes to the heart." Without going so far as to say that no man is a poet who cannot write a good song, it may certainly be said that no man can write a good song who is not a good poet.

In modern times we have, of course, nothing in any way representing those choral dance-songs of the Greeks, which, originating in the primitive Cretan war-dances, became, in Pindar's time, a splendid blending of song and ballet. Nor have we anything exactly representing the Greek *scolia*, those short drinking songs of which Terpander is said to have been the inventor. That these *scolia* were written, not only by poets like Alcæus, Anacreon, Praxilla, Simonides, but also by Sappho and by Pindar, shows in what high esteem they were held by the Greeks. These songs seem to have been as brief as the *stornelli* of the Italian peasant. They were accompanied by the lyre, which was handed from singer to singer as the time for each *scolion* came round.

With regard to the *stornello*, many critics seem to confound it with the *rispetto*, a very different kind of song. The Italian *rispetto* consists of a stanza of inter-rhyming lines ranging from six to ten in number, but often not exceeding eight. The Tuscan and Umbrian *stornello* is much shorter, consisting, indeed, of a hemistich naming some natural object which suggests the motive of the little poem.

The nearest approach to the Italian *stornello* appears to be, not the *rispetto*, but the Welsh *triban*.

Perhaps the mere difficulty of rhyming in English and the facility of rhyming in Italian must be taken into account when we inquire why there is nothing in Scotland—of course there could be nothing in England—answering to the nature-poetry of the Italian peasant. Most of the Italian *rispetti* and *stornelli* seem to be improvisations; and to improvise in English is as difficult as to improvise is easy in Italian. Nothing indeed is more interesting than the improvisatorial poetry of the Italian peasants, such as the canzone. If the peasantry discover who is the composer of a canzone, they will not sing it. The speciality of Italian peasant poetry is that the symbol which is mostly erotic is of the purest and most tender kind. A peasant girl will improvise a song as impassioned as "Come into the Garden, Maud," and as free from unwholesome taint.

With regard to English songs, the critic cannot but ask—Wherein lies the lost ring and charm of the Elizabethan song-writers? Since the Jacobean period at least, few have succeeded in the art of writing real songs as distinguished from mere book lyrics. Between songs to be sung and songs to be read there is in our time a difference as wide as that which exists between plays for the closet and plays for the boards.

Heartiness and melody—the two requisites of a song which can never be dispensed with—can rarely be compassed, it seems, by one and the same individual. In both these qualities the Elizabethan poets stand pre-eminent, though even with them the melody is not so singable as it might be made. Since their time heartiness has, perhaps, been a Scottish rather than an English endowment of the song-writer. It is difficult to imagine an Englishman writing a song like "Tullochgorum" or a song like "Maggie Lauder," where the heartiness and impulse of the poet's mood conquer all impediments of close vowels and rugged consonantal combinations. Of Scottish song-writers Burns is, of course, the head; for the songs of John Skinner, the heartiest song-writer that has appeared in Great Britain (not excluding Herrick), are too few in number to entitle him to be placed beside a poet so prolific in heartiness and melody as Burns. With regard to Campbell's heartiness this is quite a different quality from the heartiness of Burns and Skinner, and is in quality English rather than Scottish, though, no doubt, it is of a fine and rare strain, especially in "The Battle of the Baltic." His songs illustrate an infirmity which even the Scottish song-writers share with the English—a defective sense of that true song-warble which we get in the *stornelli* and *rispetti* of the Italian peasants. A poet may have heartiness in plenty, but if he has that love of consonantal effects which Donne displays he will never write a first-rate song. Here, indeed, is the crowning difficulty of song-writing. An extreme simplicity of structure and of diction must be accompanied by an instinctive apprehension of the melodic capabilities of verbal sounds, and of what Samuel Lever, the Irish song-writer, called "singing" words, which is rare in this country, and seems to belong to the Celtic rather than to the Saxon ear. "The song-writer," says Lever, "must frame his song of open vowels with as few guttural or hissing sounds as possible, and he must be content sometimes to sacrifice grandeur and vigor to the necessity of selecting singing word and not reading words." And he exemplifies the distinction between singing words and

The Italian improvisatorial peasant poetry.

English songs.

reading words by a line from one of Shelley's songs—

"The fresh earth in new leaves drest,"

"where nearly every word shuts up the mouth instead of opening it." But closeness of vowel sounds is by no means the only thing to be avoided in song-writing. A phrase may be absolutely unsingable, though the vowels be open enough, if it is loaded with consonants. The truth is that in song-writing it is quite as important, in a consonantal language like ours, to attend to the consonants as to the vowels; and perhaps the first thing to avoid in writing English song is the frequent recurrence of the sibilant. But this applies to all the brief and quintessential forms of poetry, such as the sonnet, the elegy, etc.

As to the elegy—a form of poetic art which has more relation to the objects of the external world than the song, but less relation to these than the stornello—its scope seems to be wide indeed, as practiced by such various writers as Tyrtæus, Theognis, Catullus, Tibullus, and our own Gray. It may almost be said that perfection of form is more necessary here and in the sonnet than in the song, inasmuch as the artistic pretensions are more pronounced. Hence even such apparent minutiae as those we have hinted at above must not be neglected here.

We have quoted Dionysius of Halicarnassus in relation to the arrangement of words in poetry. His remarks on sibilants are equally deserving of attention. He goes so far as to say that σ is entirely disagreeable, and, when it often recurs, insupportable. The hiss seems to him to be more appropriate to the beast than to man. Hence

Perfection of detail demanded in the quintessential forms of poetry.

certain writers, he says, often avoid it, and employ it with regret. Some, he tells us, have composed entire odes without it. But if sibilation is a defect in Greek odes, where the softening effect of the vowel sounds is so potent, it is much more so in English poetry, where the consonants dominate, though it will be only specially noticeable in the brief and quintessential forms such as the song, the sonnet, the elegy. Many poets only attend to their sibilants when these clog the rhythm. To write even the briefest song without a sibilant would be a *tour de force*; to write a good one would no doubt be next to impossible. It is singular that the only metricist who ever attempted it was John Thelwall, the famous "Citizen John," friend of Lamb and Coleridge, and editor of the famous *Champion* newspaper where many of Lamb's epigrams appeared. Thelwall gave much attention to metrical questions, and tried his hand at various metres. Though "Citizen John's" sapphics might certainly have been better, he had a very remarkable critical insight into the rationale of metrical effects, and his "Song without a sibilant" is extremely neat and ingenious. Of course, however, it would be mere pedantry to exaggerate this objection to sibilants even in these brief forms of poetry.

As a fine art English poetry is receiving much attention in our time. Defective rhymes once allowable, and makeshift work in general, are no longer tolerated. And we believe the time is not far distant when even such a subject as vowel composition (the arrangement of one vowel sound with regard to another) will have to be studied with the care which the Greeks evidently bestowed upon it. (T. W.)

POGGENDORFF, JOHANN CHRISTIAN (1796–1877), physicist, and editor for more than half a century of the well-known scientific journal called after him *Poggendorff's Annalen*, was born in Hamburg on the 29th December, 1796. His father, a wealthy manufacturer of that town, was all but ruined by the French siege. His son Christian, after receiving his education at Hamburg and Schiffbeck, had therefore, when only sixteen, to apprentice himself to an apothecary in Hamburg, and when twenty-two began to earn his living as an apothecary's assistant at Itzehoe. Ambition and a strong inclination towards a scientific career led him to throw up his business and remove to Berlin, where he entered the university in 1820. Here his abilities were speedily recognized, and in 1823 he was appointed meteorological observer to the Academy of Sciences with a small salary, which was important to him, inasmuch as the expenses of his university career had nearly exhausted his slender patrimony. Even at this early period he had conceived the idea of founding a physical and chemical scientific journal. The realization of this plan was hastened by the sudden death of Gilbert, the editor of *Gilbert's Annalen der Physik*, in 1824. Poggendorff immediately put himself in communication with the publisher, Barth of Leipsic, with the result that he was installed as editor of a scientific journal which was to be a continuation of *Gilbert's Annalen* on a somewhat extended plan, indicated by its title *Annalen der Physik und Chemie*. Poggendorff was admirably qualified for the post which he thus attained. He had an extraordinary memory, well-stored with scientific knowledge, both modern and historical, which served him in good stead in the critical part of his editorial duty. He had a cool and impartial judgment, with a strong preference for facts as against theory of the speculative kind at least, and was able to throw himself into the spirit of modern experimental science, represented in the early part of his editorial career by such great names as Berzelius, Faraday, Brewster, Fresnel, Regnault. He also possessed in more than German measure the German virtue of orderliness in the arrangement of knowledge and in the conduct of business.

To this he added an engaging geniality of manner and much tact in dealing with men; so marked in fact was this part of his character that, notwithstanding his somewhat trying position, he never during his long life was involved in anything that could be fairly called a literary quarrel. These qualities of its editor soon made *Poggendorff's Annalen* the foremost scientific journal in Europe. He collected around him all the eminent scientific men of his own country, and he managed either through original contributions or by translations of memoirs of approved value already printed, to secure for many years an adequate representation of the scientific work of other lands. So true is this that, for years after the beginning of Poggendorff's editorship, the tables of contents of his annual volumes read like an index of the history of physical science.

In the course of his fifty-two years' editorship of the *Annalen* Poggendorff could not fail to acquire an unusual acquaintance with the labors of modern men of science. This knowledge, joined to what he had gathered by historical reading of equally unusual extent, he carefully digested and gave to the world in his *Biographisch-literarisches Handbuch zur Geschichte der Exacten Wissenschaften*, containing notices of the lives and labors of mathematicians, astronomers, physicists, chemists, mineralogists, geologists, etc., of all peoples and all ages. The two volumes of this work contain an astounding collection of facts invaluable to the scientific biographer and historian; they form in fact the basis of the yet unwritten history of physical science. We possess a small fragment of such a history in the form of lectures delivered by Poggendorff himself at Berlin; and probably he had contemplated at one time writing a continuous narrative; but even his long life was too short for the double task of collecting and using the material.

Poggendorff was a physicist of high although not of the very highest rank. He was wanting in mathematical ability, and never displayed in any remarkable degree the still more important power of scientific generalization, which, whether accompanied by mathematical skill or not, never fails to mark the highest genius

in physical science. He was, however, an able and conscientious experimenter. He was very fertile and ingenious in devising physical apparatus, and contributed greatly in the earlier part of his life to enrich the resources of experimental science. Contemporaneously with Schweigger, he succeeded in greatly increasing the sensitiveness of the galvanometer by introducing the multiplying coil, and he made important improvements on that particular type of this instrument which is usually called the sine galvanometer. To him (according to Wiedemann) we owe the use of binding screws in most of their various forms. He invented the "Inversor" for rapidly alternating the direction of a voltaic current, and the "Wippe" for throwing a number of voltaic or electrolytic cells suddenly into "series" or into "multiple arc"; and to him is due the suggestion of the telescope and mirror method for reading galvanometers and other physical instruments, a device which has proved very valuable in all branches of physical science.

Poggendorff's contributions to physics were published for the most part in his own journal. They form an important part of the scientific work of the 19th century; but it would be difficult in a few words to characterize them inasmuch as they do not constitute a single coherent group or even a few coherent groups of connected researches. By far the greater and more important part of his work related to electricity and magnetism. As specimens we may mention his investigations into the working of Holtz's machines, and his variations on their construction; his researches on the resistance and electro-motive force of electrolytic cells, along with which ought to be noticed his admirable method of comparing electro-motive forces by "compensation"; and finally his researches on magnetism and diamagnetism.

Poggendorff's literary and scientific reputation speedily brought him honorable recognition. In 1830 he was made royal professor and in 1834 Hon. Ph.D. and extraordinary professor in the university of Berlin, and in 1839 member of the Berlin Academy of Sciences. He ultimately became a member of many foreign societies, and received more than the usual share of the orders bestowed by Continental nations for scientific merit. During his lifetime many offers of ordinary professorships were made to him, but he declined them all, devoting himself to his duties as editor of the *Annalen*, and to the pursuit of his scientific researches. He died at Berlin on January 24, 1877.

POGGIO (1380-1459). Gian Francesco Poggio Bracciolini, eminent in the annals of the revival of learning, was born in 1380 at Terranova, a village in the territory of Florence. He studied Latin under John of Ravenna, and Greek under Manuel Chrysoloras. His distinguished abilities and his dexterity as a copyist of MSS. brought him into early notice with the chief scholars of Florence. Coluccio Salutati and Niccolò de' Niccoli befriended him, and in the year 1402 or 1403 he was received into the service of the Roman curia. His functions were those of a secretary; and, though he profited by benefices conferred on him in lieu of salary, he remained a layman to the end of his life. It is noticeable that, while he held his office in the curia through that momentous period of fifty years which witnessed the councils of Constance and of Basel, and the final restoration of the papacy under Nicholas V., his sympathies were never attracted to ecclesiastical affairs. Nothing marks the secular attitude of the Italians at an epoch which decided the future course of both Renaissance and Reformation more strongly than the mundane proclivities of this apostolic secretary, heart and soul devoted to the resuscitation of classical studies amid conflicts of popes and antipopes, cardinals and councils, in all of which he bore an official part. Thus, when his duties called him to Constance in 1414, he employed his leisure in exploring the libraries of Swiss and Swabian convents. The treasures he brought to light at Reichenau, Wein-

garten, and above all at St. Gall, restored many lost masterpieces of Latin literature, and supplied students with the texts of authors whose works had hitherto been accessible only in mutilated copies. In one of his epistles he describes how he recovered Quintilian, part of Valerius Flaccus, and the commentaries of Asconius Pedianus at St. Gall. MSS. of Lucretius, Columella, Silius Italicus, Manilius, and Vitruvius were unearthed, copied by his hand, and communicated to the learned. Wherever Poggio went he carried on the same industry of research. At Langres he discovered Cicero's *Oration for Cæcina*, at Monte Cassino a MS. of Frontinus. He also could boast of having recovered Ammianus Marcellinus, Nonius Marcellus, Probus, Flavius Caper, and Eutyches. If a codex could not be obtained by fair means, he was ready to use fraud, as when he bribed a monk to abstract a Livy and an Ammianus from the convent library of Hersfeld. Resolute in recognizing erudition as the chief concern of man, he sighed over the folly of popes and princes, who spent their time in wars and ecclesiastical disputes when they might have been more profitably employed in reviving the lost learning of antiquity. This point of view is eminently characteristic of the earlier Italian Renaissance. The men of that nation and of that epoch were bent on creating a new intellectual atmosphere for Europe by means of vital contact with antiquity. Poggio, like a still more eminent humanist of his age, Æneas Sylvius Piccolomini, was a great traveller, and wherever he went he brought, like Æneas Sylvius, enlightened powers of observation trained in liberal studies to bear upon the manners of the countries he visited. We owe to his pen curious remarks on English and Swiss customs, valuable notes on the remains of antique art in Rome, and a singularly striking portrait of Jerome of Prague as he appeared before the judges who condemned him to the stake. It is necessary to dwell at length upon Poggio's devotion to the task of recovering the classics, and upon his disengagement from all but humanistic interests, because these were the most marked feature of his character and career. In literature he embraced the whole sphere of contemporary studies, and distinguished himself as an orator, a writer of rhetorical treatises, a panegyrist of the dead, a violent impugner of the living, a translator from the Greek, an epistolographer and grave historian, and a facetious compiler of fabliaux in Latin. Of his moral essays it may suffice to notice the dissertations *On Nobility*, *On Vicissitudes of Fortune*, *On the Misery of Human Life*, *On the Infelicity of Princes*, and *On Marriage in Old Age*. These compositions belonged to a species which, since Petrarch set the fashion, were very popular among Italian scholars. They have lost their value, except for the few matters of fact imbedded in a mass of commonplace meditation, and for some occasionally brilliant illustrations. Poggio's *History of Florence*, written in avowed imitation of Livy's manner, requires separate mention, since it exemplifies by its defects the weakness of that merely stylistic treatment which deprived so much of Bruni's, Carlo Aretino's, and Bembo's work of historical weight. A somewhat different criticism must be passed on the *Facetiae*, a collection of humorous and indecent tales expressed in such Latinity as Poggio could command. This book is chiefly remarkable for its unsparing satires on the monastic orders and the secular clergy. It is also noticeable as illustrating the Latinizing tendency of an age which gave classic form to the lightest essays of the fancy. Poggio, it may be observed, was a fluent and copious writer in the Latin tongue, but not an elegant scholar. His knowledge of the ancient authors was wide, but his taste was not select and his erudition was superficial. His translation of Xenophon's *Cyropaedia* into Latin cannot be praised for accuracy. Among contemporaries he passed for one of the most formidable polemical or gladiatorial rhetoricians, and a considerable section of his extant works are invec-

tives. One of these, the *Dialogue against Hypocrites*, was aimed in a spirit of vindictive hatred at the vices of ecclesiastics; another, written at the request of Nicholas V., covered the anti-pope Felix with scurrilous abuse. But his most famous compositions in this kind are the personal invectives which he discharged against Filelfo and Valla. All the resources of a copious and unclean Latin vocabulary were employed to degrade the objects of his satire; and every crime of which humanity is capable was ascribed to them without discrimination. In Filelfo and Valla Poggio found his match, and Italy was amused for years with the spectacle of their indecent combats. To dwell upon such literary infamies would be below the dignity of the historian, were it not that these habits of the early Italian humanists imposed a fashion upon Europe which extended to the later age of Scaliger's contentions with Scioppius and Milton's with Salmasius. The greater part of Poggio's long life was spent in attendance to his duties in the papal curia at Rome and elsewhere. But about the year 1452 he finally retired to Florence, where he was admitted to the burghership, and, on the death of Carlo Aretino in 1453, was appointed chancellor and historiographer to the republic. He had already built himself a villa in Valdarno, which he adorned with a collection of antique sculpture, coins, and inscriptions. In 1435 he had married a girl of eighteen named Vaggia, of the famous Buondelmonte blood. His declining days were spent in the discharge of his honorable Florentine office and in the composition of his history. He died in 1459 and was buried in the church of Sante Croce. A statue by Donatello and a picture by Antonio del Pollajuolo remained to commemorate a citizen who chiefly for his services to humanistic literature deserved the notice of posterity.

Poggio's works were printed at Basel in 1538, "ex ædibus Henrici Petri." Dr. Shepherd's *Life of Poggio Bracciolini* is a good authority on his biography. For his position in the history of the revival, students may consult Voigt's *Wiederbelebung des classischen Alterthums* and Symond's *Renaissance in Italy*. (J. A. S.)

POGY, a popular name for the fish *Clupea menhaden*, almost universally in use in the States of Maine and Massachusetts (see *MENHADEN*, vol. xvi. p. 14).

POINSOT, LOUIS (1777-1859), mathematician, was born at Paris, January 3, 1777. In 1794 he became a scholar at the Polytechnic School, which he left in 1796 to act as a civil engineer. In 1804 he was appointed professor of mathematics at the Lyceum, in 1809 professor of applied mathematics and in 1816 examiner at the Polytechnic School. On the death of Lagrange in 1813 Poinsot was elected to his place in the French Academy; and in 1840 he became a member of the superior council of public instruction. In 1846 he was made an officer of the legion of honor; and on the formation of the senate in 1852 he was chosen a member of that body. He died at Paris December 5,¹ 1859. Poinsot's earliest work was his *Éléments de Statique*, in which he introduces the idea of statical couples and investigates their properties. In the *Théorie Nouvelle de la Rotation des Corps* he treats the motion of a rigid body geometrically, and shows that the most general motion of such a body can be represented at any instant by a rotation about an axis combined with a translation parallel to this axis, and that any motion of a body of which one point is fixed may be produced by the rolling of a cone fixed in the body on a cone fixed in space. The previous treatment of the motion of a rigid body had in every case been purely analytical and so gave no aid to the formation of a mental picture of the body's motion, and the great value of this work lies in the fact that, as Poinsot himself says in the introduction, it enables us to represent to ourselves the motion of a rigid body as clearly as that of a moving point. Poinsot also contributed a number

of papers on pure and applied mathematics to *Liouville's Journal* and to the *Journal of the Polytechnic School*.

POINT DE GALLE. See GALLE, vol. x. p. 37.

POINTE À PITRE, the principal port of the island of GUADELOUPE (*q.v.*).

POISONS. An exact definition of the word "poison" is by no means easy. There is no legal definition of what constitutes a poison, and the definitions usually proposed are apt to include either too much or too little. Generally, a poison may be defined to be a substance having an inherent deleterious property, rendering it capable of destroying life by whatever avenue it is taken into the system; or it is a substance which, when introduced into the system or applied externally, injures health or destroys life irrespective of mechanical means or direct thermal changes. In popular language, a poison is a substance capable of destroying life when taken in small quantity; but a substance which destroys life by mechanical means, as, *e.g.*, powdered glass, is not, strictly speaking, a poison.

The subject of toxicology forms one of the most important branches of MEDICAL JURISPRUDENCE (*q.v.*). The medical jurist should be familiar with the nature and actions of poisons, the symptoms which they produce, the circumstances which modify their working, the pathological results of their action, and the methods of combating these.

Action of Poisons.—Poisons may exert a twofold action. This may be either local or remote, or both local and remote. The local action of a poison is usually one of corrosion, inflammation, or a direct effect upon the sensory or motor nerves. The remote actions of poisons are usually of a specific character, though some writers group the remote effects of poisons under two heads, and speak of the common and the specific remote effects of a poison. The local action of a poison of the corrosive class is usually so well marked and obvious that the fact of the administration of a poison of this class is generally unmistakable. The same may be said, in a less degree, of the irritant poisons, especially the mineral irritants; but here the symptoms sometimes so closely simulate those of natural disease as to render the recognition of the administration of poison a matter of difficulty. Hence an accurate acquaintance with the remote specific effects of the various poisons is indispensable to the medical jurist. The class of poisons which has been administered or taken will thus be suggested to his mind by the observation of the symptoms, and not unfrequently the specific poison taken will be suspected. It is almost universally admitted that absorption of a poison is necessary for the production of its specific remote effects, and the old notion that a poison may kill, by its action through the nervous system, without absorption, is abandoned.

Modifying Circumstances.—The ordinary action of a poison may be greatly modified by the largeness of the dose, by the state of aggregation, admixture, or of chemical combination of the poison, by the part or membrane to which it is applied, and by the condition of the patient. Thus, for example, opium may be a medicine or a poison according to the dose in which it is given; and a dose of the drug which may be beneficial to an adult in certain states of the system may be fatal to a child, or to an adult when suffering from some forms of disease. All barium salts, again, are poisonous, except the quite insoluble sulphate. The simple cyanides, and many double cyanides, are highly poisonous; but yellow prussiate of potash, which is a double cyanide of iron and potassium, is almost without action upon the system. The part or tissue to which a poison is applied greatly affects the activity of a poison, owing to the varying rapidity with which absorption takes place through the cutaneous, mucous, and serous surfaces, and by the other tissues of the body. Curare, an arrow poison, may be swallowed in considerable quantity without appreciable results,

¹ [Merlieux, in *Biographie Générale*, and Larousse say 15th Dec.—AM. Ed.]

whilst a minute quantity of the same substance introduced into a wound is speedily fatal. Idiosyncrasy has an important bearing in toxicology. Pork, mutton, certain kinds of fish, more especially shell fish so-called, and mushrooms have each produced all the symptoms of violent irritant poisoning, whilst other persons who have partaken of the same food at the same time have experienced no ill effects. Some persons are stated, on good authority, to be capable of taking with impunity such poisons as opium, corrosive sublimate, or arsenic, in enormous doses,—and this irrespective of habit, which is known to have such an influence in modifying the effects of some poisons, notably the narcotics. A tolerance of poisons is sometimes engendered by disease, so that a poison may fail to produce its customary effect. Thus, opium is tolerated in large quantities in tetanus, and in delirium tremens; and mercurial compounds may in some febrile affections fail to produce the usual constitutional effects of the metal. On the other hand, diseases which impede the elimination of a poison may intensify its effects.

The evidence that a poison has been administered is based upon the symptoms produced, on the appearances met with in the body after death, on the analysis of articles of food and drink, of excreta and ejecta, and of the organs of the body after death, and on physiological experiments made with substances extracted from the same articles. These physiological experiments are usually made upon animals, but in some cases, as for instance when aconite has to be searched for, the physiological experiments must be made also upon the human subject. The evidence obtained from one or more of these sources, as compared with the properties or effects of various known poisons, will enable the medical jurist to form an opinion as to the administration or non-administration of a poison.

The symptoms exhibited by the patient during life rarely fail to afford some clue to the poison taken. Persons may, however, be found dead of whose history nothing can be learned. Here post-mortem appearances, chemical analysis, and, it may be, physiological experiments are all important for the elucidation of the nature of the case.

Poisoning may be *acute* or *chronic*. The general conditions which should arouse a suspicion of acute poisoning are the sudden onset of serious and increasingly alarming symptoms in a person previously in good health, especially if there be pain in the region of the stomach, or, where there is complete prostration of the vital powers, a cadaveric aspect, and speedy death. In all such cases the aid of the analytical chemist must be called in either to confirm well-founded or to rebut ill-founded suspicions.

The mode of treatment to be adopted in the case of poisoned persons varies greatly according to the nature of the poison. The first indication, when the poison has been swallowed, is to evacuate the stomach; and this may usually be done by means of the stomach-pump when the poison is not of the corrosive class; or the stomach may be gently washed out by means of a funnel and flexible siphon-tube. In many cases emetics are valuable. Antidotes and counter-poisons may then be given. The former are such substances as chalk to neutralize the mineral acids and oxalic acid; the latter have a physiological counter-action, and are such as atropine, which is a counter-poison to morphia. These may usually be administered most effectively by hypodermic injection. The stomach may to a certain degree be protected from the injurious effects of irritants by the administration of mucilaginous drinks; alkaloids may be rendered sparingly soluble by means of astringent substances containing tannin; and pain may be relieved by means of opium, unless contra-indicated by the nature of the poison. The effects of the convulsant poisons, such as strychnine, may be combated by means of the inhalation of chloroform.

The classification of poisons is a matter of difficulty.

Various attempts have been made to classify them scientifically, but with no signal success; and perhaps the best system is that which groups the various poisons according to the more obvious symptoms which they produce. Our knowledge of the more intimate action of poisons is still too imperfect to admit of any useful classification according to the manner in which they specifically affect the vital organs. Poisons may in the manner indicated be classified as (1) *Corrosives*, (2) *Irritants*, (3) *Neurotics*, and (4) *Gaseous Poisons*. The subject of poisonous food has already been treated under the heading MEDICAL JURISPRUDENCE (vol. xv. pp. 792-793).

1. *Corrosives*.

The typical member of this class is corrosive sublimate, the soluble chloride of mercury. In it are included also the concentrated mineral acids (sulphuric, nitric, and hydrochloric); oxalic acid; the alkalies (potash, soda, and ammonia) and their carbonates; acid, alkaline, and corrosive salts of the metals (such as bisulphate of potash, alum, butter of antimony, and nitrate of silver); also carbolic acid.

The symptoms produced by the mineral acids and the alkalies are almost altogether referable to local action; but some corrosive poisons, such as carbolic acid, produce, besides a local action, remote and specific constitutional effects. The symptoms of corrosive poisoning are marked and unmistakable, except in infants. Immediately on swallowing the corrosive substance, an acid, caustic, or metallic burning sensation is experienced in the mouth, fauces, gullet, and region of the stomach, and this speedily extends over the whole belly; as a rule vomiting speedily follows. In the case of the mineral acids, and in oxalic acid poisoning, the vomit is so acid that if it falls upon a marble or concrete floor effervescence ensues. No relief follows the evacuation of the stomach. The ejected matters contain blood, and even fragments of the corroded walls of the alimentary canal. The belly becomes distended with gas, and horribly tender. High fever prevails. The mouth is found to be corroded. Death usually ensues within a few hours; or, if the patient survives, he or she may perish miserably, months after the poison was taken, through starvation consequent upon the gradual contraction of the gullet, brought about by its corrosion and subsequent healing.

The treatment of corrosive poisoning consists in very gently emptying and washing out the stomach by means of a soft siphon-tube. The stomach-pump cannot be used with safety in consequence of the weakening of the walls of the stomach by corrosion. Demulcents and opiates may be subsequently administered. After death from corrosive poisoning the walls of the stomach are found corroded, and even perforated.

1. *Corrosive Sublimate*.—Here all the signs and symptoms of corrosive poisoning are produced in their severest form. A grain or two of this poison may prove fatal. Fortunately there is an efficient antidote in white of egg, the albumen of which, if administered at once, renders the salt insoluble. The eggs should be divested of their yolks, beaten up with water, and given promptly, repeatedly, and abundantly, followed by emetics. Poisoning by corrosive sublimate may be followed by the specific toxic effects of mercury, such as salivation and tremor.

Workers in mercury, such as water-gilders, looking-glass makers, and the makers of barometers and thermometers, are apt to suffer from a peculiar form of shaking palsy, known as "the trembles," or mercurial tremor. This disease affects most frequently those who are exposed to mercurial fumes. The victim is affected with tremors when an endeavor is made to exert the muscles, so that he is unable, for instance, to convey a glass of water to the lips steadily, and when he walks he breaks into a dancing trot. The treatment consists in removal from the mercurial atmosphere, baths, fresh air, and the administration of iron and other tonics.

2. *Mineral Acids*.—These are oil of vitriol or sulphuric acid, aqua-fortis or nitric acid, and spirit of salt or hydrochloric (muriatic) acid. These when taken in a concen-

trated form produce well-marked symptoms of corrosion. When they are diluted, the symptoms are those of an irritant poison. Nitric acid stains the mouth and skin of a yellow color. The treatment consists in the administration of alkalies or their carbonates, chalk, whiting, or even uncolored plaster scraped off the walls or ceiling, with the view of neutralizing the acid.

3. *Oxalic acid* is a vegetable acid. When taken in the state of concentrated solution it acts as a corrosive, but when diluted as an irritant. But it also exerts a specific effect, killing the patient by cardiac syncope not unfrequently within a few minutes. When a person after taking a crystalline substance, tasting strongly acid, dies within 15 or 30 minutes, after the manifestation of great weakness, small pulse, and failure of the heart's power, poisoning by oxalic acid is almost certain. The treatment consists in promptly administering an emetic, followed by chalk, whiting, or any substance containing carbonate of calcium. The alkaline carbonates are valueless, for the alkaline oxalates are almost as poisonous as oxalic acid itself.

4. *The Alkalies.*—Potash, soda, and their carbonates and sulphides produce symptoms resembling those of the mineral acids, except that purging is a usual accompaniment.

5. *Carbolic acid* when taken in the form of a concentrated liquid acts as a corrosive, causing whitening and shrinking of all the animal membranes with which it comes in contact. The patient, however, becomes speedily comatose, the poison acting prepotently upon the great nervous centres. A curious phenomenon—black or dark green urine—is commonly observed after the administration of this poison. Saccharated lime-water, diluted and drunk freely, and a solution of sulphate of soda are perhaps the most useful remedies.

2. Irritant Poisons.

Irritant poisons are of two classes—metallic irritants, and vegetable and animal irritants, these latter being for convenience grouped together. Perhaps none of the irritants act purely as such, the irritant symptoms being usually accompanied by well-marked effects upon the nervous system. An irritant is a substance which causes inflammation of the part to which it is applied—usually the alimentary canal. Arsenic is by far the most important of the metallic irritants. Other irritants are the moderately diluted acids, many metallic salts, such as those of antimony, lead, copper, zinc, and chromium. Elaterium, gamboge, aloes, colocynth, and croton oil are good examples of vegetable irritants; and cantharides of animal irritants. Animal and vegetable food when decomposed, or infested with certain organisms known as bacteria, may produce violent irritant symptoms. The symptoms produced by irritant poisons are usually more slow in their development than where a corrosive has been administered. Usually, after an interval, greater or less according to the specific nature of the irritant swallowed, a burning pain is felt in the mouth, throat, and gullet, with a sense of constriction of the parts, and followed by burning pain in the region of the stomach. This is increased, and not alleviated, by pressure, a mark which serves to distinguish the attack from one of ordinary colic. Nausea, vomiting, and thirst ensue, speedily followed by distention of the whole abdomen, which is exceedingly tender to the touch. Ordinarily the vomiting is followed by profuse diarrhoea. Should the poison not be speedily eliminated in the vomited and faecal matters, inflammatory fever sets in, followed by collapse; and death may ensue in a few hours.

There is danger of confounding irritant poisoning with some forms of natural disease, such as gastritis and gastric ulcer, colic, peritonitis, cholera, and rupture of the intestines.

1. *Arsenic* is a specific irritant poison. Almost all the compounds of this metal are poisonous. The term "arsenic" is, however, most commonly applied, not to the metal itself, but to its lower oxide, arsenious oxide, which is also known as *white arsenic*. By whatever channel arsenic is introduced into the system, it invariably affects specifically the stomach and intestines, causing congestion or inflammation. The common sources of arsenical poisoning are the taking of white arsenic, which causes acute

poisoning, and the inhalation of dust from arsenical wall-papers and textile fabrics, whereby a chronic form of poisoning is induced.

The symptoms of acute arsenical poisoning do not come on, as in the case of corrosive poisoning, immediately after the poison is swallowed. There is usually an interval of half an hour or so before prominent symptoms supervene. Generally, after a feeling of faintness and depression, an intense burning pain is felt in the region of the stomach, with tenderness on pressure. Nausea and vomiting generally follow, increased by every act of swallowing. Unlike what occurs in ordinary vomiting, the pain and sickness are not relieved by the evacuation of the stomach. Vomiting is followed by purging, blood being frequently distinguishable in the evacuations. There is thirst, a feeble irregular pulse, and a perspiring clammy skin. The victim usually succumbs within eighteen to seventy-two hours; if he survives the latter period, good hopes may be entertained of his recovery. The treatment consists in the use of the stomach-pump, emetics, such as mustard and warm water, demulcents, and the free administration of magnesia emulsion and either freshly precipitated ferric hydrate or dialysed iron. Ferric hydrate, and the solution known as dialysed iron, have the property of rendering arsenious anhydride insoluble.

Chronic arsenical poisoning is usually accidental. The inhalation of arsenical vapors in factories, or of arsenical dust from green wall-papers and in the manufacture of artificial flowers, are common sources of this form of poisoning. Arsenic when thus slowly absorbed into the system produces congestion and inflammation of the mucous membranes, redness and irritation of the conjunctivæ, sore throat, a peculiar eruption of the skin, and diarrhoea. The treatment consists in removal from the poisoned atmosphere, and the administration of tonics.

Arsenic-eating, or the ability of some persons to take relatively large doses of arsenic habitually, is a well-established fact. The cause of this singular immunity from the ordinary results of arsenic is quite unknown.

2. *Lead.*—The salts of lead, more especially the acetate (sugar of lead), are irritant poisons of no very great activity; and, though occasionally death ensues, recovery is the rule. Chrome yellow, or lead chromate, is a powerful irritant poison. All chromates are, indeed, irritant poisons.

Chronic lead poisoning is a much more common affection than acute irritant poisoning by lead. When lead in any form is slowly absorbed into the system, a peculiar affection results, known as saturnine poisoning, and characterized by two prominent symptoms—colic and paralysis. Workers in lead and its compounds, such as plumbers and painters, are frequently affected by this form of disease. Water, especially soft water or such as is contaminated with sewage, on being passed through leaden pipes or stored in leaden cisterns may become contaminated with lead to a dangerous extent. Acid liquids, such as cider, vinegar, etc., may also contain lead as an impurity. Potmen, who drink beer which has rested for some time in pewter vessels, are also the occasional victims of saturnine poisoning. Water which contains lead in a soluble form to the extent of more than one-tenth of a grain per gallon should not be used for drinking purposes. If more than this quantity be present, the water when placed in a white porcelain dish will become more or less dark in color on the addition of a few drops of a solution of sulphuretted hydrogen.

The commonest manifestation of chronic lead poisoning is lead colic,—a peculiar twisting and agonizing sensation around the navel, attended with obstinate constipation. This, like all forms of chronic lead poisoning, is almost invariably attended with a peculiar blue line on the margin of the gums, and when this is present the nature of the affection can scarcely be doubtful. The treatment consists in the free use of purgatives, opiates, and the internal use of potassium iodide, which favors the elimination of the metal through the urine. "Wrist-drop" or lead paralysis is also a common result of the ingestion of lead. It consists in a paralysis of the extensor muscles of the forearm, accompanied by a wasting of that structure. A dropping of the wrist is the result of this degeneration. Baths, the use of galvanism, and the administration of potassium iodide and tonics usually afford relief. Should, however, the patient in any form of lead poisoning be exposed for a lengthened period to the effects of the metal, degenerations of the liver, kidneys, and brain supervene, with fatal results.

In all cases of lead poisoning removal of the exciting cause is indispensable; the worker in lead must suspend his occupation for a time; the use of contaminated articles of food or drink must cease.

3. *Copper.*—The soluble salts of copper, such as blue vitriol (the sulphate) and verdigris (subcarbonate and sub-

acetate), are emetic and irritant salts. Their emetic effects usually, but not invariably, secure their prompt rejection by the stomach. Occasionally fatal effects have resulted from their administration. Copper becomes accidentally mixed with articles of dietary in a variety of modes. It is also used for improving the color of preserved fruits and vegetables. Its deleterious properties when thus used in minute quantities have been both asserted and denied. There is, however, a large body of evidence in favor of the at all events occasional poisonous effects of minute quantities of copper.

4. *Zinc salts and barium salts*, except the quite insoluble barium sulphate, are irritant poisons; and barium compounds act also upon the central nervous system.

5. *Chromates*, e.g., bichromate of potash, are violent irritants. Chrome yellow, or lead chromate, has already been mentioned.

6. *Phosphorus*.—Of the two chief forms of the elements—the yellow or ordinary and the red or amorphous—the former only is poisonous. Rarely there is met with a chronic form of poisoning among workers in the material, arising from the inhalation of phosphorus vapors. Its special characteristic is a peculiar necrosis or death of the bony structure of the lower jaw. Acute phosphorus poisoning is more common. Phosphorus is used for tipping matches, and is also the basis of several vermin destroyers. When swallowed, phosphorus produces a variable amount of irritation and disturbance of the alimentary canal. There may be a burning sensation felt in the mouth, throat, and stomach, followed by vomiting. The vomited matters, and also the excreta, may be observed to be luminous in the dark. These symptoms usually subside, and for three or four days the person appears to have recovered his or her usual health. The liver then enlarges, and this and other structures undergo fatty degeneration; jaundice supervenes; and the patient dies in a few days in a semi-typoid condition. Rarely there is recovery. Oil of turpentine is thought to be the best remedy. Most of the organs undergo fatty degeneration.

7. *Vegetable Irritants*.—These produce drastic purgative effects. Frequently the nature of the illness may be ascertained by the discovery of portions of the vegetable substance—recognizable by the microscope—in the matters ejected by the patient.

8. *Cantharides*.—The administration of CANTHARIDES (*q.v.*) is followed by vomiting, purging, strangury, or even entire inability to pass the urine. In the ejecta portions of the shining elytra or wing-cases of the fly may often be recognized. There is often great excitement of the sexual proclivities. The active principle of the fly, cantharidin, may be extracted from suspected matters by means of chloroform, and the residue left after the evaporation of this blisters the lip or any tender mucous surface to which it is applied. Demulcent remedies, with opiate enemata and injections, afford the best relief by way of treatment.

3. Neurotics.

It is premature, for the present, to attempt a systematic division of this most important class, which embraces poisons so widely different in their actions as opium and strychnine. We at once proceed to details.

1. *Prussic or Hydrocyanic Acid*.—Hydrocyanic acid is one of the best-known poisons, and a very deadly one. In the pure state it is said to kill with lightning-like rapidity. It is met with in commerce only in a dilute state. In Great Britain two kinds of acid are commonly sold—the pharmacopœial acid, containing 2 per cent. of anhydrous prussic acid, and Scheele's acid, containing 4 or 5 per cent. Less than a teaspoonful of the 2 per cent. acid has caused death. Given in fatal doses, the symptoms of prussic-acid poisoning set in with great rapidity; and, in consequence of the readiness with which the poison is absorbed from the stomach and diffused through the circulation, the onset of symptoms is reckoned by seconds rather than by minutes. Occasionally the victim may be able to perform a few voluntary actions before alarming symptoms are developed. There is first a very brief stage of difficult breathing, and slow action of the heart, with a tendency for the organ to stop in the state of dilatation. With widely-dilated pupils of the eye, the patient is then seized with violent irregular convulsive movements. The rhythm of the respiratory movements is disturbed, and the countenance becomes of a bluish cast. The patient now sinks to the ground with complete loss of muscular power; and the third or asphyxial stage is reached, in which there are slow gasping respirations, loss of pulse, and paralysis of motion. Death is frequently preceded by muscular spasms. The found-

royant character of the illness, and the speedy death of the patient, coupled with the peculiar odor of the acid in the breath and atmosphere around the body, seldom leave any doubt as to the nature of the case. The treatment consists in inhalation of the fumes of strong ammonia, drinks of warm and cold water alternately, friction of the limbs, and artificial respiration. The subcutaneous injection of atropine, which acts as a cardiac stimulant, may prove serviceable.

Other soluble cyanides, more especially cyanide of potassium, a salt largely used in photography and in the arts, are equally poisonous with hydrocyanic acid. See PRUSSIC ACID.

2. *Opium*.—In consequence of the extent to which OPIUM (*q.v.*), its preparations, and its active alkaloid morphia are used for the relief of pain, poisoning by opium is of frequent occurrence. It is largely used by suicides; and children, being very susceptible to its influence, frequently die from misadventure after administration of an overdose of the drug. The ordinary preparations of opium are the drug itself, which is the inspissated juice of the Oriental poppy, and the tincture, commonly known as laudanum. Opium contains a variety of more or less active principles, the chief of which is the alkaloid morphia, which is present in good opium to the extent of about 10 per cent. in combination with meconic acid, which is physiologically inactive. Opium is largely used by Eastern nations for smoking, and there is great discrepancy of opinion as to the extent to which opium smoking is deleterious. The preponderance of opinion is in favor of the view that opium smoking is a demoralizing, degrading, and pernicious habit, and that its victims are sufferers both in body and mind from its use.

The first symptom of the administration of a poisonous dose of opium is a state of exaltation—which may not, however, be well-marked—soon passing into a second stage, in which the symptoms are those of congestion of the brain. The countenance is suffused and of a bluish cast, known as cyanosis, due to imperfect aeration of the blood; the pupils of the eyes are minutely contracted, the skin dry and warm, and the breathing slow, labored, and becoming stertorous. The patient is apparently unconscious, but may be roused by shaking, or by shouting into the ear. When this has taken place, the breathing becomes more natural, and the skin less cyanosed. If he be left alone there is a speedy relapse into a state of insensibility. If effective treatment be not adopted, a third stage of prostration supervenes, in which there is profound coma, and it may be impossible to arouse the patient. The pupils of the eyes are now contracted to the size of pin-points. Breathing is slow, shallow, and intermittent. The countenance is at once pallid and cyanosed, the skin bathed in perspiration. The pulse becomes more rapid with increased feebleness, and at length all signs of it are lost, until death supervenes.

The treatment consists in the use of the stomach-pump. Emetics are usually inoperative. After this the patient must be kept awake by walking him about, applying cold and warm douches alternately to the chest, shouting into the ears, flicking the hands and feet with damp towels, and the application of the galvanic current. Circulation should be promoted by friction of the limbs and trunk. Strong infusion of coffee, ammonia, and alcoholic stimulants may be freely administered. As a last resort when the breathing intermits, artificial respiration may be performed. The hypodermic injection of full doses of atropine has proved of marked benefit, atropine and morphia being to a certain extent counter-poisons.

Opium is a drug to which its victims may become habituated by the use of gradually increasing doses; and the practice of opium-eating, as it is termed, is a pernicious one. An atrophied condition of the body usually results. The only remedy is abstinence from the drug.

3. *Strychnine and Strychnine-yielding Plants*.—The alkaloids strychnine and brucine, as well as all the plants in which they are found, all act in the same manner, being highly poisonous, and causing death after spasms of a severe character. Strychnine was first extracted from the seeds of *Strychnos Nux-Vomica* in 1819, by Pelletier and Caventou. It exists in larger quantity in other species of the genus *Strychnos*, and notably in *Strychnos Ignatii*. From the bark of *Strychnos Nux-Vomica*, known as false Angostura bark, another alkaloid, brucine is also extracted. This bark was at one time wrongly supposed to be the bark of *Brucea antidysenterica*; hence the name *brucia* or brucine. Its effects are similar to those of strychnine, but its physiological activity is not so great. Many vermin-killers contain strychnine as their active ingredient.

Strychnine, and all substances containing that alkaloid, produce their effects within a very few minutes—usually

within ten or fifteen minutes. The patient complains of stiffness about the neck, and his aspect exhibits terror. There is an impression of impending calamity or death. Very speedily the head is jerked back, the limbs extended, the back arched (opisthotonos), so that the body may rest on the head and heels only. The mouth is drawn; and the condition is one known as tetanus. In a few moments these symptoms pass off, and there is complete relaxation of the spasm. The spasmodic condition speedily returns, and is brought about by the slightest touch or movement of the patient. Accessions and remissions of the tetanic state ensue rapidly till the patient succumbs, usually within half an hour of the administration of the poison. The best treatment is to put, and keep, the patient under the influence of chloroform till time is given for the excretion of the alkaloid, having previously given a full dose of chloral hydrate.

4. *Aconite Poisoning*.—The ordinary blue rocket, wolfsbane or monkshood, *Aconitum Napellus*, and an alkaloid extracted from it, aconitine, are perhaps the most deadly of known poisons. One-sixteenth of a grain of aconitine has proved fatal to a man. All the preparations of aconite produce a peculiar burning, tingling, and numbness of the parts to which they are applied. When given in large doses they produce violent vomiting, as a rule, more or less paralysis of motion and sensation, and great depression of the heart, usually ending in death from syncope. Intelligence remains unaffected till almost the last. The treatment consists in the hypodermic injection of tincture of foxglove (*Digitalis*) or its active principle digitalin, which is a counter poison in its action upon the heart. The root of aconite has been eaten in mistake for that of horse-radish.

5. *Belladonna*.—The belladonna or deadly nightshade, *Atropa Belladonna*, contains an alkaloid, atropine, which is largely used by oculists to procure dilatation of the pupils of the eye. The bright scarlet berries of the plant have been eaten by children, who are attracted by their tempting appearance. Belladonna produces dilatation of the pupils, rapid pulse, hot dry flushed skin, with an eruption not unlike that of scarlatina, soreness of the throat, with difficulty of swallowing, intense thirst, and gay mirthful delirium. The treatment consists in evacuation of the poison by means of the stomach-pump, and the hypodermic injection of morphia as a counter-poison.

4. Gaseous Poisons.

The effects of these are varied,—some of them acting as irritants, while others have a specific effect, apparently in consequence of their forming chemical compounds with the red pigment of the blood, and thus destroying its capability of acting as a carrier of oxygen.

1. *Chlorine and bromine* act as powerful irritants. They provoke spasms of the glottis when inhaled, and subsequently induce inflammation of the respiratory mucous membrane, which may prove speedily fatal. Inhalation of diluted ammonia vapor is the best remedy.

2. *Hydrochloric or muriatic acid gas and hydrofluoric or fluoric acid gas* are irritating and destructive to life. The former is more destructive to vegetable life than even chlorine. They are emitted in many processes of manufacture, and especially in the manufacture of carbonate of soda from common salt by Le Blanc's process, in the salt-glazing of earthenware and in the manufacture of artificial manures.

3. *Sulphurous Acid Gas*.—The gas given off by burning sulphur is most suffocating and irritating. Its inhalation, even in a highly diluted state, may cause speedy death from spasmodic closure of the glottis.

4. *Nitrous vapors, or gaseous oxides of nitrogen* (except nitrous oxide), are given off from galvanic batteries excited by nitric acid; also in the process of etching on copper. They produce, when diluted, little immediate irritation, but are exceedingly dangerous, setting up extensive and fatal inflammation of the lungs.

5. *Ammonia gas* is highly irritant, but does not often prove fatal.

6. *Carbonic acid gas* is heavier than atmospheric air, is totally irrespirable when pure, and is fatal when present in large quantities in respired air. It is given off from burning fuel, accumulates in pits and wells as choke-damp, and constitutes the deadly after-damp of coal-mines. It is also formed during alcoholic fermentation, and hence accumulates in partially filled vats in which fermented liquors are stored. When it is breathed in a concentrated state, death is almost instantaneous. Persons descending into wells foul with this gas sink down powerless, and are usually dead before they can be removed from the vitiated atmosphere. In these cases there is true asphyxia; but carbonic acid is also a narcotic gas. Persons exposed to an atmosphere partially

composed of this gas, but not long enough to produce fatal results, are affected with stertorous breathings, oppression, flushed face, prominent eyes, swollen tongue, and feeble pulse. The proper treatment is removal from the foul atmosphere, alternate cold and tepid douches to the chest, friction of the limbs and trunk, and artificial respiration. When animation is restored the patient should be put to bed and kept quiet, but should be carefully watched in case of relapse.

7. *Carbonic oxide gas* is given off by burning charcoal and other forms of fuel, mixed with carbonic acid. The poisonous effects of charcoal fumes are perhaps due rather to the more poisonous carbonic oxide than to the less poisonous carbonic acid. An atmosphere containing less than 1 per cent. of carbonic oxide would doubtless be fatal if breathed for many minutes. Carbonic oxide forms with hæmoglobin, the red pigment of the blood, a bright scarlet compound. The compound is very stable, and the oxide cannot be displaced by atmospheric oxygen. Hence the blood after death from the inhalation of carbonic oxide is of a bright arterial hue, which it retains on exposure to air.

8. *Coal-gas* acts as an asphyxiant and narcotic. The appearances met with after death—more especially the fluid state of the blood—are similar to those observed after death from carbonic oxide gas, which is a constituent of coal-gas, and to which the chief effect of coal-gas may be due.

9. *Sulphuretted hydrogen gas* is highly poisonous by whatever channel it gains access to the body. In a concentrated form it produces almost instant death from asphyxia. Even in a diluted state it produces colic, nausea, vomiting and drowsiness. This may pass into insensibility with lividity and feeble respiration. The skin is cold and clammy, or bathed in perspiration. The red blood corpuscles are disintegrated. The treatment consists in removal from the contaminated atmosphere, friction to the surface of the body, warmth, and the administration of stimulants. The inhalation of chlorine gas has been recommended on chemical grounds; but it must be remembered that chlorine is itself poisonous.

10. *Anæsthetics*.—Nitrous oxide, or laughing gas, and the gases or vapors of other anæsthetic substances, such as chloroform, produce death by asphyxia, and perhaps otherwise. Obviously, as a rule, medical assistance is at hand. The treatment consists in artificial respiration, and the use of galvanic current.

11. *Vapors of Hydrocarbons*.—The volatile vapors of the natural hydrocarbons known as benzoline, petroleum, etc., are poisonous when inhaled for lengthened periods.

(T. S. *)

POISSON, SIMÉON DENIS (1781-1840), a celebrated French mathematician, was born at Pithiviers in the department of Loiret, on the 21st June, 1781. His father, Siméon Poisson, served as a common soldier in the Hanoverian wars; but, disgusted by the ill treatment he received from his patrician officers, he deserted. About the time of the birth of his son Siméon Denis he occupied a small administrative post at Pithiviers, and seems to have been at the head of the local government of the place during the revolutionary period. The infant Poisson was put out to nurse, and concerning his nursing Arago relates the following story, which he had from its hero himself. One day the anxious father went to visit his son, but found that the nurse had gone to the fields. Impatient, he broke into the cottage, and there saw, with painful astonishment, the object of all his hopes suspended by a small cord to a nail fixed in the wall. This was a precaution on the part of the peasant nurse to prevent her charge from perishing under the teeth of the carnivorous and unclean animals that circulated in the house. Poisson, in telling the story, added—"A gymnastic effort carried me incessantly from one side of the vertical to the other; and it was thus, in my tenderest infancy, that I made my prelude to those studies on the pendulum that were to occupy so much of my maturer age."

Having survived the perils of infancy, and received the elements of his education (reading and writing) from his father, the question arose what calling he was to follow. It was at first suggested that he should be made a notary; but the family council, with amusing irony, decided that this profession made too great demands upon the intellect, and surgery was preferred. He was sent to an uncle who exercised

this art at Fontainebleau, and forthwith began to take lessons in bleeding and blistering, then the leading branches of a surgeon's practice. To train him in the former, he was set to prick the veins of cabbage leaves with a lancet but made little progress; how he sped in the latter he himself relates as follows: "Once my uncle sent me, with one of my comrades, M. Vanneau, now established in the colonies, to put a blister on the arm of a child; the next day, when I presented myself to remove the apparatus, I found the child dead; this event, very common they say, made the most profound impression upon me; and I declared at once that I would never be either physician or surgeon. Nothing could shake my resolution, and they sent me back to Pithiviers." Here accident and the bent of nature solved the problem that had passed the wisdom of the family council. The elder Poisson, being a Government official, received a copy of the *Journal de l'École Polytechnique*; the son read it, and soon began unaided to solve the problems propounded there from time to time; and thus his mathematical talent was discovered. He was sent to the École Centrale of Fontainebleau, and was fortunate in having a kind and sympathetic teacher, M. Billy, who, when he speedily found that his pupil was becoming his master, devoted himself to the study of higher mathematics in order to follow and appreciate him, and predicted his future fame by the punning quotation from Lafontaine¹—

"Petit Poisson deviendra grand
Pourvu que Dieu lui prête vie."

At the age of seventeen the young provincial, less remarkable for the elegance of his attire than for the profundity of his scientific knowledge, came up to Paris to undergo the entrance examination for the Polytechnic School. He passed first in his year, and immediately began to attract the notice of the professors of the school, who, seeing his obvious genius, excused him from the ordinary drudgery of the curriculum, and left him free to follow the studies of his predilection. The wisdom of this course was soon proved; for, in 1800, less than two years after his entry, he published two memoirs, one on Bezout's method of elimination, the other on the number of integrals of an equation of finite differences. The latter of these memoirs was examined by Lacroix and Legendre, who recommended that it should be published in the *Recueil des Savants Étrangers*, an unparalleled honor for a youth of eighteen. This success at once procured for Poisson an entry into the Parisian scientific society of the day, the like of which for brilliancy has never elsewhere been seen. Its two kings both patronized him. Lagrange, whose lectures on the theory of functions he attended at the Polytechnic School, early recognized his talent, and became his friend; while Laplace, in whose footsteps Poisson followed, regarded him almost as his son. The rest of his career, till his death on the 25th of April, 1840, was almost entirely occupied in the composition and publication of his many works, and in discharging the duties of the numerous educational offices to which he was successively appointed. Immediately after finishing his course at the Polytechnic School he was appointed répétiteur there, an office which he had discharged as an amateur while still a pupil in the school; for it had been the custom of his comrades often to resort to his room after an unusually difficult lecture to hear him repeat and explain it. He was made professeur suppléant in 1802, and full professor in succession to Fourier in 1806. In 1808 he became astronomer to the Bureau des Longitudes; and when the Faculté des Sciences was instituted in 1809, he was appointed Professeur de la Mécanique Rationnelle. He further became member of the Institute in 1812, examiner at the military school at St. Cyr in 1815, leaving examiner at the Polytechnic in 1816, councillor of the university

in 1820, and geometer to the Board of Longitude in succession to Laplace in 1827.

In 1817 he married Mademoiselle Nancy de Bardi, daughter of a French family which had emigrated to England, and by her he had two sons and two daughters.

Poisson was a simple-minded affectionate man. This is seen in the close relations which he kept up with his old teacher M. Billy, who ardently loved and admired his former pupil, and whose presence at the Institute was a well-known sign that Poisson was to read a paper there. Although he never returned to Pithiviers after his entry into the Polytechnic School, he corresponded constantly with his parents, more especially with his mother; and he regularly sent copies of his memoirs to his father, who read and re-read with unwearied patience the parts of them within his comprehension. His tastes seem to have been of the simplest description; he took little exercise and he had more than a Frenchman's horror of travelling. Arago says that he only travelled once, and that by medical prescription, disguised under the form of some mission connected with the Polytechnic School, and that, after devoting his savings to the purchase of a beautiful farm in the department of Seine-et-Marne, he never so much as visited it.

It is probable that his simplicity of character had much to do with his passing apparently quite undisturbed through the stormy time in which he lived, a period in which many men of mark lost their heads, and few such escaped without loss of office and fortune. His father, whose early experiences led him to hate aristocrats, bred him in the stern creed of the first republic. Throughout the empire Poisson faithfully adhered to the family principles, and refused to worship Napoleon. Napoleon, however, never interfered with Poisson's promotion. He said once himself that he never did anything uselessly, certainly never committed a useless crime; and he was wise enough to see that nothing was to be gained by persecuting the harmless academician, whose fame he doubtless regarded like that of the other savants of France as an apauage of his own glory. When the Bourbons were restored, his hatred against Napoleon led him to become a Legitimist—a conclusion which says more for the simplicity of his character than for the strength or logic of his political creed.

He was faithful to the Bourbons during the Hundred Days, in fact was with difficulty dissuaded from volunteering to fight in their cause. After the second restoration his fidelity was recognized by his elevation to the dignity of baron in 1825; but he never either took out his diploma or used the title. The revolution of July, 1830, threatened him with the loss of all his honors; but this disgrace to the government of Louis Philippe was adroitly averted by Arago, who, while his "revocation" was being plotted by the council of ministers, procured him an invitation to dine at the Palais Royale, where he was openly and effusively received by the citizen king, who "remembered" him. After this, of course, his degradation was impossible; he was left in undisturbed possession of all his well-earned appointments; and seven years later he was made a peer of France, not for political reasons, but as a representative of French science.

As a teacher of mathematics Poisson is said to have been more than ordinarily successful, as might have been expected from his early promise as a répétiteur at the Polytechnic School. As a scientific worker his activity has rarely if ever been equalled. Notwithstanding his many official duties, he found time to publish more than three hundred works, several of them extensive treatises, and many of them memoirs dealing with the most abstruse branches of pure and applied mathematics. There are two remarks of his, or perhaps two versions of the same remark, that explain how he accomplished so much: one, "La vie n'est bonne qu'à deux choses—à faire des mathé-

¹ This prediction is sometimes attributed to Laplace.

matiques et à les professer ;" the other, "La vie c'est le travail."

A list of Poisson's works, drawn up by himself, is given at the end of Arago's biography. A lengthened analysis of them would be out of place here, and all that is possible is a brief mention of the more important. There are few branches of mathematics to which he did not contribute something, but it was in the application of mathematics to physical subjects that his greatest services to science were performed. Perhaps the most original, and certainly the most permanent in their influence, were his memoirs on the theory of electricity and magnetism, which virtually created a new branch of mathematical physics. They have been already repeatedly referred to in the articles *ELECTRICITY* and *MAGNETISM* (*q.v.*). Next (perhaps in the opinion of some first) in importance stand the memoirs on celestial mechanics, in which he proved himself a worthy successor to Laplace. The most important of these are his memoirs "Sur les inégalités séculaires des moyens mouvements des planètes," "Sur la variation des constantes arbitraires dans les questions de mécanique," both published in the *Journal of the Polytechnic School*, 1809; "Sur la libration de la lune," in *Connaiss. d. Temps*, 1821, etc.; and "Sur la mouvement de la terre autour de son centre de gravité," in *Mém. d. l'Acad.*, 1827, etc. In the first of these memoirs Poisson discusses the famous question of the stability of the planetary orbits, which had already been settled by Lagrange to the first degree of approximation for the disturbing forces. Poisson showed that the result could be extended to a second approximation, and thus made an important advance in the planetary theory. The memoir is remarkable inasmuch as it roused Lagrange, after an interval of inactivity, to compose in his old age one of the greatest of his memoirs, viz., that "Sur la théorie des variations des éléments des planètes, et en particulier des variations des grands axes de leurs orbites." So highly did he think of Poisson's memoir that he made a copy of it with his own hand, which was found among his papers after his death. Poisson made important contributions to the theory of attraction. His well-known correction of Laplace's partial differential equation for the potential was first published in the *Bulletin de la Société Philomatique*, 1813. His two most important memoirs on the subject are "Sur l'attraction des sphéroïdes" (*Connaiss. d. Temps*, 1829), and "Sur l'attraction d'un ellipsoïde homogène" (*Mém. d. l'Acad.*, 1835). In concluding our selection from his physical memoirs we may mention his memoir on the theory of waves (*Mém. d. l'Acad.*, 1825).

In pure mathematics, his most important works were his series of memoirs on definite integrals, and his discussion of Fourier's series, which paved the way for the classical researches of Dirichlet and Riemann on the same subject; these are to be found in the *Journal of the Polytechnic School* from 1813 to 1823, and in the *Memoirs of the Academy* for 1823. In addition we may also mention his essay on the calculus of variations (*Mém. d. l'Acad.*, 1833), and his memoirs on the probability of the mean results of observations (*Connaiss. d. Temps*, 1827, etc.).

Besides his many memoirs Poisson published a number of treatises, most of which were intended to form part of a great work on mathematical physics, which he did not live to complete. Among these may be mentioned his *Traité de Mécanique*, 2 vols. 8vo, 1811 and 1833, which was long a standard work; *Théorie Nouvelle de l'Action Capillaire*, 4to, 1831; *Théorie Mathématique de la Chaleur*, 4to, 1835; *Supplément* to the same, 4to, 1837; *Recherches sur la probabilité des jugements en matières criminelles*, etc., 4to, 1837, all published at Paris.

Enough has been said to establish Poisson's fertility as a writer on mathematical subjects, and the question naturally suggests itself, What is his rank among the mathematicians of all ages? Since his own age was more productive of great mathematicians than any other the world has yet seen, it is natural to compare him with his contemporaries, chief among whom were Lagrange and Laplace. In so doing, we see at once that, although we cannot seat him alongside of these mighty sovereigns, yet it is impossible to deny him the nearest rank to them in the temple of mathematical fame. In confirmation of this judgment, we cannot do better than quote one of them—"I am old," said Lagrange to Poisson one day; "during my long intervals of sleeplessness I divert myself by making numerical approximations. Keep this one; it may interest you. Huygens was thirteen years older than Newton, I am thirteen years older than Laplace; D'Alembert was

thirty-two years older than Laplace, Laplace is thirty-two years older than you." Arago, who gives this story, justly remarks that no more delicate way could be conceived of intimating to Poisson his admission into the inner circle of the fraternity of mathematical genius. (G. CH.)

POITIERS, a town of France, formerly the capital of Poitou, and now the chief town of the department of Vienne, lies 206 miles southwest of Paris on the railway to Bordeaux, at the junction of the Boivre with the Clain (a tributary of the Loire by the Vienne), and occupies the slopes and summit of a plateau which rises 130 feet above the level of the streams by which it is surrounded on three sides. The town is picturesque; and its narrow, ill-paved, irregular, and deserted streets with their ill-built houses are interesting for certain remains of ancient architecture and the memories of great historical events. Blossac park, named after the intendant of the "generality" of Poitiers (1751-1786), and situated on the south side of the town, and the botanic garden on the northeast, are the two principal promenades. Besides being the see of a bishopric, which comprises the departments of Vienne and Deux-Sèvres, Poitiers possesses a court of appeal, national faculties of law, literature, and science, a free faculty of Catholic theology, a school of artillery, and numerous learned societies, of which the most celebrated is that of the "Antiquaires de l'Ouest" dating from 1834. Though not strictly a commercial or industrial town, it is the centre from which railways branch out to Tours, Angers, Niort, Angoulême, Limoges, and prospectively to Châteauroux and Nantes. Up till 1857 it contained the ruins of a Roman amphitheatre more extensive than that of Nîmes; remains of Roman baths, constructed in the 1st and demolished in the 3d century, were laid bare in 1877; and in 1879 a pagan burial place and the tombs of a number of Christian martyrs were discovered on the heights to the southeast—the names of some of the Christians being preserved in paintings and inscriptions. Not far from these tombs is a huge dolmen (the "Pierre Levée"), 22 feet long, 16 feet broad, and 6 or 7 feet high, around which used to be held the great fair of St. Luke.

The cathedral of St. Peter, begun in 1162 by Eleanor of Guienne on the ruins of a Roman basilica, and well advanced at the time of her death in 1204, is a building after the Plantagenet or Angevin style. Its length is 308 feet, its width 128, and the keystone of the central vaulted roof is 89 feet above the pavement. There is no apse, and the exterior generally has a heavy appearance. The principal front has unfinished side towers 105 and 110 feet in height, begun in the 13th century. Most of the windows of the choir and the transepts preserve their stained glass of the 12th and 13th centuries; the end window, which is certainly the first in the order of time, contains the figures of Henry II. of England and Eleanor. The choir stalls, carved between 1235 and 1257, are the oldest in France. The church of St. Jean (originally a baptistery) near the cathedral is the most ancient Christian monument in the country. The church of St. Hilaire was erected at the close of the 4th century over the tomb of the celebrated bishop. At first an unpretending oratory, it was rebuilt on a larger scale by Clovis, and afterwards became, in the 10th, 11th, and 12th centuries, a sumptuous collegiate church, of which the nave was flanked by triple aisles and surmounted by six cupolas. Great damage was done to it in the wars of religion and the French Revolution. The confessional or oratory under the choir contains the relics of St. Hilary and a Christian sarcophagus of the 4th century. The church of St. Radegonde, a great resort of pilgrims, commemorates the consort of Hlothar I. (c. 550), and preserves in its crypt, not only the tomb of Radegonde, who founded at Poitiers the abbey of the Holy Cross, but those of St. Agnes and St. Disciola. The church is in the Angevin style; the

choir is of the 11th, and the nave of the 13th century. Notre Dame la Grande, which dates from the close of the 11th century, and represents a collegiate church one or two hundred years older, has a richly sculptured Romanesque façade. The first stone of the church of Moutierneuf (*Monasterium Novum*) was laid in 1077 by William, duke of Aquitaine and count of Poitiers, who is buried within its walls; and the choir (afterwards in the 13th century modified by the erection of a "lantern") was solemnly consecrated by Urban II. in 1096. Mutilated about 1640 and during the Revolution, the building was partly restored between 1850 and 1860. The tower of St. Porchaire, a precious remnant of 11th-century architecture, has been restored in the present generation under the auspices of the Antiquaires de l'Ouest and the French archaeological society. Other churches of interest are the Chapel of the Lycée, that of the Sisters of the St. Croix, and the old church of the Jesuits.

Among the secular buildings the first place belongs to the law courts, formerly the palace of the dukes of Aquitaine and counts of Poitiers, and rebuilt between the 12th and the 15th century. The Salle de Pas Perdu forms a fine nave 160 feet long by 56 feet wide, with a vaulted wooden roof. The southern wall is the work of Duke Jean de Berri, brother of Charles V.; above its three vast fireplaces are mullioned windows filled with stained glass. The Maubergeon tower attached to the palace represented the feudal centre of all the lordships of the countship of Poitiers. The prévôté or provost's mansion, now occupied by a communal school, has a fine façade of the 15th century. In the new hôtel de ville, erected between 1869 and 1876, are museums of archaeology, natural history and painting. The museum of the Antiquaires de l'Ouest occupies the chapel and the great hall of the old university, now located in the old hôtel de ville; it is a valuable collection comprising Roman antiquities, Merovingian sculptures, medals, a fine Renaissance fireplace, etc. The building devoted to the faculties of law, science and literature (of which the first dates from 1431) also contains the library (35,000 printed volumes and 300 MSS.). The municipal records are very rich in charters of Eleanor of Aquitaine, Philip Augustus, Alphonse of Poitiers, etc. Convents and religious educational establishments are numerous in the town. The population of Poitiers in 1881 was 34,355.

Poitiers, called Limonum at the time of the Roman conquest, then took the name of its Gallic founders the Pictones or Pictavi. Christianity was introduced in the 3d century, and the first bishop of Poitiers, from 350 to 367, was St. HILARIUS (q.v.). Fifty years later the city had fallen into the hands of the Arian Visigoths, and become one of the principal residences of their kings. Alaric, one of their number, was defeated by Clovis at Vouillé not far from Poitiers in 507. This was the first occasion on which the peoples of northern and southern Gaul met in conflict in the neighborhood of the town which was destined to see them so frequently join battle. By his victory in 732 over the Mohammedans at Moussais-la-Bataille in this region, Charles Martel proved the saviour of Christendom. Under the Carolingians, Poitiers was dependent on the crown and afterwards on the duchy of Aquitaine. Eleanor of Guienne, after her divorce from Louis VII., carried it to her new husband Henry Plantagenet. She frequently resided in the city, which she embellished and fortified, and in 1199 entrusted with communal rights. Philip Augustus, having confiscated the Continental territories of John of England, united Poitou to the French crown; Louis VIII. made it an apanage for his son Alphonse of Poitiers, who afterwards became count of Toulouse. At a plenary court held in 1241 in the great hall of the palais de justice, Alphonse received the homage of his numerous vassals. After his death in 1271 Poitou reverted to the crown. But, King John having been defeated and made prisoner in the disastrous battle of Poitiers (fought 4 miles E. of the town on the hillside of Nouaille, 19th September, 1356), Poitou was recognized as an English possession by the treaty of Brétigny (1360). Nine years later it was recovered by Du-guesclin; and it became in succession the apanage of Jean de Berri, brother of king Charles VI., and of the dauphin,

afterward Charles VII. It was at Poitiers that the latter was proclaimed king (1423); and he removed thither the parlement and university of Paris, which remained in exile till the English withdrew from the capital in 1436. During this interval (1429) Joan of Arc was subjected to a formal inquest by the doctors of the university. Calvin had numerous converts at Poitiers. Of the violent proceedings which attended the wars of religion the city had its share. In 1569 it was defended by Count du Lude against Coligny, who after an unsuccessful bombardment retired from the siege at the end of seven weeks.

POITOU, one of the old provinces of France, which also formed one of the great military governments of the kingdom, was bounded N. by Brittany, Anjou and Touraine; S. by Angoumois and Aunis; E. by Touraine, Berri and Marche; and W. by the ocean. It was divided into Lower Poitou, which corresponded to the modern department of La Vendée and Upper Poitou, now split into the departments of Deux-Sèvres and Vienne. The principal towns in Upper Poitou were Poitiers the capital, Mirebeau, Châtelleraut, Richelieu, Loudun, Thouars, Mauléon, Parthenay, Niort, etc.; and in Lower Poitou Fontenai-le-Comté, Maillezais, Luçon and Roche-sur-Yon. Île d'Yeu or Île-Dieu and Noirmoutier belonged to the province. Ecclesiastically Poitou was distributed among the dioceses of Poitiers, Luçon and La Rochelle; for the administration of justice, it was attached to the parlement of Paris.

Poitou (Poictou, Pictavia) takes its name from the Pictones or Pictavi, a Gallic nation mentioned by Cæsar, Strabo and Ptolemy, and described by Strabo as separated from the Namnetes on the north by the Loire. It formed part of the territory known as AQUITANIA (q.v.). For the history see POITIERS.

POKER, a game at cards—probably a development of *il frizzo* (played in Italy in the 15th century). A similar but less simple game, called *primiera*, was also played in Italy in the 16th century, whence under the name of *primero* it travelled to Spain. *La prime* is mentioned by Rabelais (16th century); and later the game of prime elaborated was played in France under the name of *l'ambigu* or *le meslé*. Prime was also played in England in the 16th century; and later a bastard kind of prime, called post and pair, was much played in the west of England. Gleek had some points of resemblance to these games. The more modern game of brag is only post and pair with variations. Poker (originally played in America) may be described as developed brag, though in some respects it "throws back" to the parent games post and pair, *l'ambigu* and *primero*.

Any number of persons may play. If a pack of fifty-two cards is played with, from five to seven players makes the best game. Sometimes an écarté pack of thirty-two cards is used, when three or four makes the best game. There are numerous varieties of poker. *Draw poker*, with fifty-two cards, is the most common.

The dealer being determined (see Laws), he puts up a sum, previously agreed on (called the *ante*), generally one *chip* or counter, and deals five cards to each player. Then each in rotation from the dealer's left looks at his cards, and either throws up his hand (called *going out of the game*), when he stakes nothing, or *chips*, i. e., puts up twice the amount of the ante (say two counters). The dealer finally looks at his hand and either goes out of the game or *makes good* his ante by putting up another counter.

The dealer then asks those in rotation who have chipped whether they will *fill their hands* (i. e., whether they will exchange any cards for an equivalent number from the top of the pack) or *play the hand dealt*.

When the hands are filled, the players to the left of the dealer have the *say* in rotation. Each player says whether he will (1) *go out of the game* (forfeiting what he has already staked; or (2) *raise*, i. e., put up a sum in addition to that already staked. As soon as any one raises, the next in rotation to say must either

(1) *go out of the game*; or (2) *see the raise, i.e.*, put up an equal amount; or (3) *go better, i.e.*, increase the raise. This continues round and round, each succeeding player being obliged either to see the stake made by the previous one, or to go better, or go out of the game.

Eventually the raising comes to an end, because either every player but one goes out of the game (when all the stakes are taken by the player who remains in, without showing his cards), or the players left in all see the last raise, no one going better. When all the stakes are thus equal, it becomes a *call*. The last to stake, who makes his raise equal to that of each of the others, *sees* them, *i.e.*, the player to his left has to show his hand, or rather such part of it as he claims to compete with. The next to the left, then similarly shows his hand, if it can beat the one first shown; if not, he throws up; and so on all round; the holder of the best hand takes the pool, and the next dealer deals.

Hands thrown up, either on a refusal to chip to fill, or on being beaten, and cards discarded when filling, are placed face down in the middle of the table, and no one is allowed to look at them.

It is usual to limit the raise to prevent very high chipping. The modern usage is to play *table stakes, i.e.*, each player puts up such an amount as he pleases at the commencement of each deal, and he cannot be raised more than he has on the table; but he has the option of making good from his pocket a previous raise which exceeds his table stake.

Value of the Hands.—1. A straight flush (sequence of five cards of the same suit). 2. Fours (four cards of the same rank, with one other card). 3. A full (three cards of the same rank, with a pair). 4. A flush (five cards of the same suit, not in sequence). 5. A straight (sequence of five cards, not all of the same suit). 6. Triplets (three cards of the same rank, with two other cards not a pair). 7. Two pairs (with one other card not of the same rank with either pair). 8. One pair (with three other cards of different ranks). 9. Highest card.

An ace may either begin or end a straight, *e.g.*, ace, king, queen, knave, ten; or, five, four, three, two, ace. By agreement an ace may be made not to rank in sequence with the two. In no case can ace occupy an intermediate position in a straight, and when an *écarté* pack is used, ace is not in a straight with the seven. A higher straight flush, or straight, wins of a lower one; the cards rank as at whist, except that ace may be highest or lowest. In combinations other than straights ace is highest. High fours win of low ones; of two fulls the one that contains the highest triplet wins; of two flushes the one that contains the highest card wins, if equal the next highest, and so on; a straight beats triplets (this is sometimes disputed, but calculation shows a straight is the less frequent hand); of two triplets, the highest wins; of two-pair hands, the highest pair wins, if both pairs are equal, the highest card; of two hands each containing a pair, the highest pair wins, if equal the highest remaining card wins; of hands containing none of the above the highest card wins, if equal the next highest, and so on. In case of an absolute tie between the best hands they divide the pool.

Variations in the Mode of Playing.—Sometimes the ante may be raised by any one who chips to fill his hand, when succeeding players must make good the raise, or go better, or go out of the game. This is a mere excuse for higher play.

The player to the dealer's left (the *age*) is generally allowed to pass the first round after the hands are filled, and to come in again. If he passes he says "my age." Also, sometimes the age puts up the ante instead of the dealer. These useless complications, which only have the effect of making the first player the last player, are better omitted.

The age is sometimes allowed to *go blind, i.e.*, to raise the ante before he sees his cards. The next player

may *double the blind, i.e.*, raise to double what the age staked; the next may *straddle the blind, i.e.*, double again; the next may *double the straddle*, and so on. Only the age can start a blind, and any one who refuses to double or straddle prevents a further raise; but he must make good the previous stake or go out. The player to the left of the last straddler has the first say *i.e.*, on looking at his hand and before filling, he declares whether he will make good or go out. Going blind, like raising the ante, is a mere pretext for higher play.

Some players do not consider straights in the game, and omit them. This makes four aces, or four kings and an ace, invincible; and it is open to the objection that if those cards are held the player is backing a certainty.

Hints to Players.—1. The dealer should generally go in, as half his stake is already up. 2. When drawing to fill a hand, it should be done off-hand and without hesitation. If in doubt, it is better to go out of the game at once. A player may lose by going in, but can never lose by going out. 3. In filling to a pair it is generally right to draw three cards, unless drawing to a low pair, with a king or ace in hand. 4. In filling to two pairs, to a four, or to a straight or flush which wants one card, exchange one. It is not advisable to chip to fill to a straight or flush wanting more than one card; a draw to a straight or flush is usually a dear purchase. With a four the hand cannot be improved by drawing; but one card should be taken that the value of the hand may be concealed. 5. In filling to triplets one card only should be drawn, or triplets are at once declared; but, 6. Players should vary their mode of discarding to mystify the opponents, and should be sometimes cautious, sometimes bold. 7. A good *poker face* is essential; the countenance should not betray the nature of the hand. Talking without regard to facts (*poker talk*) is allowed, and is considered fair; but the best players put their cards face downwards on the table and leave them there, and neither move nor speak until it is their turn to say. 8. *Bluffing* (*i.e.*, raising high on poor cards), in hopes of inducing the other players to go out of the game, may be resorted to occasionally with success; but, as a rule, the player who goes in best will come out best. When about to bluff draw only one card or no cards. 9. A straight or higher hand may be backed freely, but the other players are more likely to go on staking if the raise is by small sums at a time. The only general rule that can be given is to change the raising tactics pretty frequently.

Laws of Poker.—These vary considerably. The following are based on "the American Hoyle." *Determination of Deal.*—1. One card is given to each player. Lowest has the deal. Ace is lowest. Ties of lowest card have one card each given again. The deal goes in rotation to the left of the last dealer. *Shuffling, Cutting, and Dealing.*—2. Any one may shuffle, the dealer last. 3. The player to the dealer's right cuts at least four cards. The dealer reunites the packets. If before the deal a card is exposed, there must be a fresh cut. A blank card is usually placed under the pack to prevent exposure of the bottom card. 4. The dealer must deal from the top of the pack, one card to each player in rotation, beginning to his left. 5. If the dealer deals without having the pack cut, or shuffles after it is cut, or misses a hand, or gives too many or too few cards to any player (but see Law 6), or exposes a card in dealing, he forfeits an ante to the pool and deals again. The forfeit does not raise the other players, and the dealer must still make his first ante good when it comes to his turn, or go out of the game. (Some players merely require a fresh deal without any forfeit, and some require a player to take the card dealt him if only one card is exposed.) *Filling the Hands.*—6. If a player, after lifting any of his cards, is found to have too many or too few cards, he must go out of the game. (Some players give a hand with only four cards the option of going in.) 7. If, when drawing to fill, the dealer gives the player too many or too few cards, and the player lifts any of them, he must go out of the game. If the error is discovered before lifting, it can be rectified—in the case of too many cards by withdrawing

the superfluous ones, in the case of too few cards by filling from the top of the pack. 8. If, when drawing to fill, a card is exposed, it must be placed at the bottom of the pack, and the top card given instead (sometimes the top card after all the other players are served). 9. Cards thrown out must be placed face downwards in the middle of the table before any are drawn; otherwise the player is liable to the penalty for holding too many cards (Law 6). 10. Any player before taking up his filled hand may ask how many cards the dealer drew. *Chipping*.—11. If all the players pass without chipping to fill, the dealer takes back his ante, and the deal passes. If, after filling, no one before the dealer raises, the dealer takes the pool. 12. If a player chips with more or less than five cards (but see note to Law 6), he must go out of the game. But, if all the other players have gone out of the game before the discovery is made, there is no penalty. 13. A player who passes or throws up cannot come in again. 14. Players are bound to put up distinctly the amount they chip, separate from their other chips. *Aftercomers*.—15. The place of an aftercomer is determined by dealing a card between every two players. The aftercomer sits where the lowest card was dealt. *Incorrect Packs*.—16. The deal in which an imperfection of the pack is discovered is void. All preceding deals stand good. (H. J.)

POKROVSKAYA SLOBODA, or **POKROVSK**, also **KASAKSTADT**, a village of the district of Novouzen, in the government of Samara, Russia, on the left bank of the Volga, almost opposite Saratoff. In the 18th century it was a small cluster of clay huts occupied by a number of runaway serfs who had gathered round the storehouses erected by the crown for salt brought from Lake Elton; but, a body of free settlers having been enticed to the spot in 1747 by large grants of grazing ground, the village rapidly increased, its inhabitants, who numbered 12,776 in 1859, now exceeding 20,000. They support themselves by cattle breeding and agriculture; and the Pokrovskaya landing place is one of the most important on the Voiga—the exports, mostly of wheat, reaching 99,850 cwts. in 1880.

POLA, the principal naval harbor and arsenal of the Austrian-Hungarian monarchy, is picturesquely situated at the south extremity of the peninsula of Istria, 55 miles to the south of Trieste. Its safe and commodious harbor is almost completely landlocked, and there is also a good roadstead between its mouth and the Brionian Islands. The harbor is divided into two basins by a chain of three small islands, and the inner basin is subdivided into the naval and the commercial harbor by the Scoglio Olivi, a larger island connected with the mainland by an aqueduct. The hills enclosing the harbor are defended by forts and batteries. The town proper lies opposite the Scoglio Olivi, round the base of a hill formerly crowned by the Roman capitol and now by a castle of the 17th century. Besides the castle the chief mediæval and modern buildings are the cathedral (15th century), the Franciscan convent (13th century), the Government and municipal offices, the huge infantry barracks, and the theatre. To the southwest, along the coast, extends the marine arsenal, a vast and well-planned establishment employing about 2000 workmen and possessing all the requisites for the equipment of

a large fleet. It contains an interesting naval museum, and is supplemented by the docks and wharves of the Scoglio Olivi. The artillery laboratory and the powder magazine are on the north bank of the harbor. Behind the arsenal lies the suburb of San Policarpo, almost exclusively occupied by the naval population and containing large naval barracks and hospitals. In the middle of it is a pleasant park, with a handsome monument to the Emperor Maximilian of Mexico, who had been a rear-admiral in the Austrian navy. To the north, between San Policarpo and the town proper, rises the Monte Zarro, surmounted by an observatory and a statue of Admiral Tegetthoff. Pola has no manufactures outside of its naval stores, but its shipping trade is now considerable, the exports consisting of fish, timber, and quartz sand used in making Venetian glass, and the imports of manufactured and colonial wares. The population has increased from 600 at the close of last century and 5000 in 1857 to 25,175 in 1880, including a garrison of 5000 men. To many people, however, the chief interest of Pola centres in its fine Roman remains. The most extensive of these is the amphitheatre, which is 400 feet long and 320 feet wide, and could accommodate 20,000 spectators. It is remarkable as the only Roman amphitheatre of which the outer walls have been preserved intact; the interior, however, is now completely bare—though the arrangements for the naumachiæ, or naval contests, can still be traced. The oldest Roman relic is the fine triumphal arch of the Sergii, erected soon after the battle of Actium; and of not much later date is the elegant and well-preserved temple of Augustus and Roma. Among the other antiquities are three of the old town-gates and a fragment of a temple of Diana.

The foundation of Pola is usually carried back to the mythic period, and ascribed to the Colchian pursuers of Jason and the Argonauts. In all probability it was a Thracian colony, but its verifiable history begins with its capture by the Romans in 178 B.C. It was destroyed by Augustus on account of its espousal of the cause of Pompey, but was rebuilt on the intercession of his daughter Julia, and received (according to Pliny) the name of Pietas Julia. It seems to have attained its greatest prosperity about the time of the emperor Septimius Severus (193–211 A.D.), when it was an important war harbor and contained 35,000 to 50,000 inhabitants. At a later period Pola became the capital of the margraves of Istria, and was more than once captured and plundered by the Venetians, who finally made themselves masters of the peninsula. In 1379 the Genoese, after defeating the Venetians in a great naval battle off the coast, took and destroyed Pola, which disappears from history for the next four hundred and fifty years. It remained under Venetian supremacy down to 1797, and has been permanently united with Austria since 1815. In 1848 a new era began for Pola in its being selected as the principal naval harbor of Austria, and since then its progress has been constant.

POLAND.

POLAND (the Polish *Polska*, German *Polen*, French *Pologne*) was till towards the end of the 18th century a large and powerful kingdom, extending with Lithuania, which was incorporated with it, over the basins of the Warta, Vistula, Dwina, Dnieper, and upper Dniester, and having under its dominion, besides the Poles proper and the Baltic Slavs, the Lithuanians, the White Russians, and the Little Russians or Ruthenians.

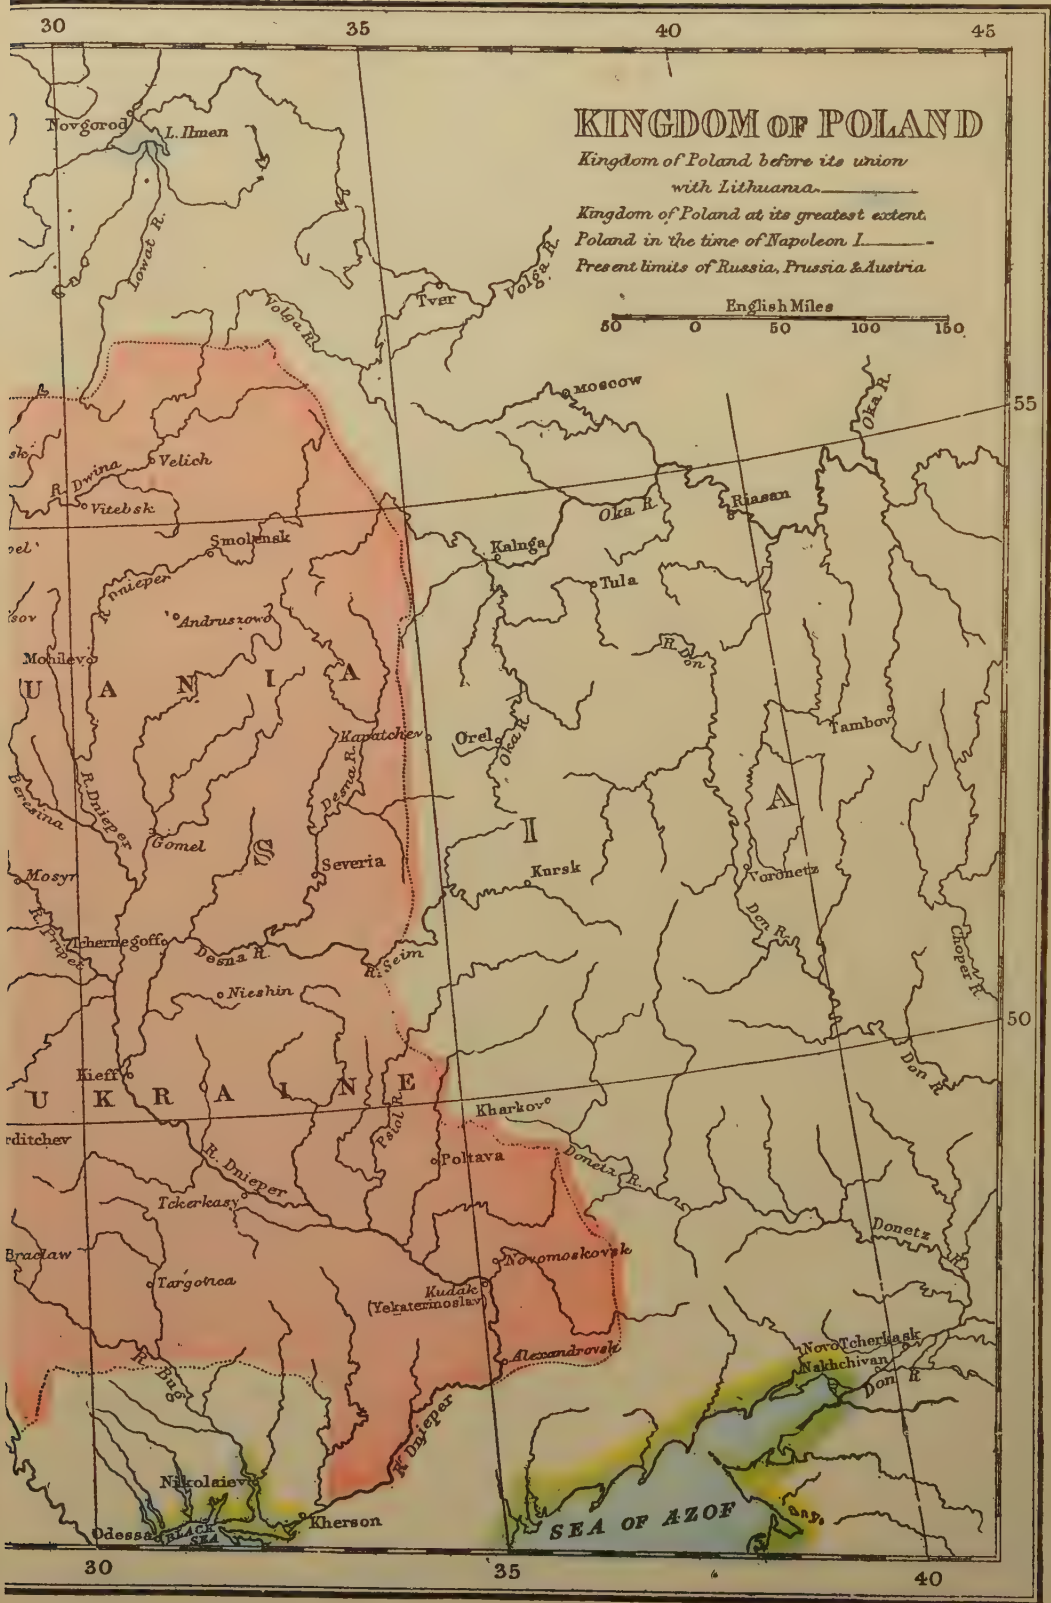

If Schafarik is correct in seeing the name of the Poles in the *Bulanes* of the geographer Ptolemy, we

should have this Slavonic people mentioned as early as the 2d century after Christ.¹ There can be no doubt about the derivation of the name; the country is one vast plain, and thus the Poles come to mean dwellers of the plain or field (*polě*). Jordanes has no distinct name for them, although he speaks of Slavs inhabiting the banks of the Vistula. About the 6th or 7th century we find a people called Lekhs settled near that river and this appears to be the oldest

The
Lekhs.

¹ There is another reading, *Sulanes* or *Sulones*; but the former is preferred by the best editors.

name which we can possibly assign to the Poles. These Lekhs are considered by Szajnocha and some of the modern school of historians to have been a Norse tribe who in the 6th century ruled over the Slavonic peoples from the Baltic to the Carpathians. And, if this were the case, the origin of the Polish kingdom would be traced to the same source as the Russian empire. No satisfactory etymology has been given as yet of the word Lekh or Lech; we cannot accept Schafarik's attempt to connect it with *szlachta*, nobility, as that word is in all probability derived from the German *geschlecht*. From the form of the word *Lech*, Russian *Liakh*, we can see that the vowel represents a suppressed nasal, and this is further proved by the change which it undergoes in the neighboring languages; thus in Lithuanian we get *Lenkas* and in Magyar *Lengyel*. The chronicle of Thomas, archdeacon of Spalato, calls them *Lingones* (Bielowski, *Mon. Hist. Pol.*), the Polish chronicles of Mierzwa and of Vincent Kadlubek *Lenchitoe*, *Linchitoe*. The loss of the nasal in the modern Polish form is curious, and contrary to the analogy of the language; it is supposed to have disappeared under the influence of Russian pronunciation. In the 13th century Kadlubek invented the imaginary *heros eponymus* Lekh, supposed to have been the father of the Poles, and two brothers were found for him, Czech and Rus.¹ A great similarity has been noticed between these early heroes and others among the Czechs. Thus we may compare Cracus and Krok, Piast and Přemysl. Many of the legendary tales greatly resemble Scandinavian sagas, as indeed much of the early Russian history does which is contained in the chronicle of Nestor. Gradually the name Lekh was superseded by Poliani or Polaki. Nestor, the old Russian chronicler, or at least the work which goes under his name, knows both appellations and distinguishes between *Poliane Liakhove* on the Vistula and *Poliane Rousove* on the Dnieper. When we first become acquainted with the Poles we find them like the other Slavonic peoples living in a kind of democratic communism, to which we need not assign the patriarchal simplicity and happiness in which some of their chroniclers, e.g., Dlugosz, would make us believe. All the early period of Polish history is mixed up with fables. Their first writers Gallus, Kadlubek, Dlugosz, Kromer, and others, who were ecclesiastics and used the Latin language as their literary medium and handled it with considerable dexterity, have treated these stories as genuine history,—just as Holinshed, Milton, Sir Richard Baker, and others did the Arthurian legends. The careful criticism, however, of modern times has relegated them to their proper place, and Lelewel has classified all the period of Polish history from the earliest times to the reign of Mieczystaw I. as belonging to the era of myths. We are hardly likely to believe in the existence of a Duke Lech or a beautiful Princess Wanda, who flourished in the 8th century, or in Cracus, said to have been the founder of Cracow. All these are obviously only generic and national names individualized. Many of the quaint and striking stories of these princes have done duty in all the legendary history of Europe. It cannot be doubted that poems corresponding to the Russian *byliny* are imbedded in the writings of these early chroniclers. The good peasant Piast, from whom was derived the celebrated line of kings, reminds us of the Mikoula Selianinovich of the Russians and the Přemysl of the Czechs. Kromer has tricked out the legend of his call to the throne in all the graces of his elegant Latinity.

Bielowski, the editor of the *Monumenta Polonica Historica*, in his *Wstęp Krytyczny do Dziejów Polski*² ("Critical Introduction to Polish History") endeavored to prove that the

original Poles dwelt on the banks of the Danube, from which they were driven by the Romans. He also attempts to trace them in the 2d and 3d centuries after Christ. According to the whimsical theory of this author—a man to whom Slavonic history in other respects owes so much—the original habitation of the Poles was by the Lake of Ochrida. The *Lęchites* (*Lyncestæ*) in the 3d century before Christ were driven by the Celts beyond the Danube, and there the kingdom of Dacia was founded. King Boirebista is Leszek II., Decebalus is Semowit, etc. Ielewel and Bielowski seem to have identified all the Thracian peoples with the Slavs.

All that we are told of the early Slavs shows them to have been a quiet agricultural people. We find them at first living in village communities with a tribal government. Nestor says, "The Poliani lived in separate groups, and each governed his family." Gradually a class of serfs sprung up, whose origin cannot be clearly traced. Röpell in his history supposes that they were the descendants of rival tribes who had been conquered. At all events we soon find the following divisions of society among the Poles: (1) the nobility, *szlachta*, who throughout Polish history constitute the nation properly so-called; (2) a superior class of peasants who were personally free, but bound to perform certain services (these are always called in the old Polish documents *cmietones*, or *kmetones*, Polish *kmięci*; and (3) the peasants strictly so called, who were the property of their masters and had no rights. We shall see how there was gradually formed in Poland a proud military aristocracy, which circumscribed the power of the king by the *pacta conventa*, so that he became a mere puppet in their hands. The nobles had absolute power over their serfs, as each separate palatinate had its tribunals. In course of time the *kmięci* became mere bondsmen. The miserable condition of the latter is seen in such books as Connor's *Letters on Poland*, published at the conclusion of the 17th century. Connor, who was physician to John Sobieski, had good opportunities for forming an opinion. Thus the trade of the country fell wholly into the hands of foreigners and Jews.

With the reign of Mieczystaw I. (962-992) we begin to have something firmer in our grasp. He became a suitor for the hand of Dąbrowka, the daughter of the king of Bohemia. Being a Christian she refused to give her hand to a pagan, and Mieczystaw consented to be baptized in 965. He had been previously conquered by the Germans, who seem to have enforced conversion from all whom they brought into subjection. After this he proceeded to extirpate the worship of idols in as autocratic a manner as Vladimir had employed, when at Kieff Peroun, the god of war, was thrown from his pedestal and ignominiously cast into the Dnieper. In 980 an edict was issued that every Pole who had not already submitted to baptism should immediately undergo it. No opposition was offered to this strange decree, which from its easy adoption would seem to have left but little impression upon the neophytes, and probably the chroniclers have some reason for their assertion that Mieczystaw himself subsequently relapsed into gross sins. This complete conversion of the nation appears to have been aided by the labors of St. Adalbert, bishop of Prague. Such traces as remained of the early Orthodox creed which had been introduced from Moravia were effaced, although they remained for some time in the sister kingdom of Bohemia, and we find a monastery established by the emperor Charles IV. for Greek monks at Prague. Mieczystaw acknowledged himself to be the feudatory of Otho of Germany; he also resisted the encroachments of Vladimir of Russia, for already

¹ For a further discussion of this subject, see the indexes to M. Leger's *Nestor* (p. 328), and especially the *Archiv für Slavische Philologie* (vol. iii., *Ueber die Namen für Polen und Lechen*, by Prof. Nehrung, and vol. iv., *Polen, Ljachen, Wenden*, by Prof. Perwolf).

² The following directions for pronunciation may be useful;

c = ts; cz = ch; sz = sh; ż = zh (the French *j*, as in *jour*); *has a thick sound which can only be acquired by ear. In nearly every word the accent is on the penult.

the feud between the two nations was commencing. He died in 992 universally regretted, as we are told, and was succeeded by his son Bolesław, surnamed the Great. During his reign Otho III. of Germany paid him a visit, and the Polish prince received him with such magnificence that the emperor elevated his duchy into a kingdom, probably intending that it should always remain a fief of the empire. Długosz and Kromer vie with each other in describing the splendor of this meeting; they are, however, far outdone by their predecessor Gallus, who speaks of magnificent military manœuvres prepared by Bolesław to delight his guest, and of the gorgeous array of the lords and court ladies; "for gold," he adds, "was at this time held as common as silver, and silver as cheap as straw." Finally, Otho hailed Bolesław as king, and himself put the diadem upon his head. At his departure he presented the Polish king with the lance of St. Maurice, still to be seen, as Kromer tells us, in the cathedral of Cracow; and Bolesław in turn offered as a gift the arm of St. Adalbert, the patron saint of Poland. Lelewel treats the whole story of this coronation as a myth, because, as he observes, at that time kings were always crowned by bishops. Bolesław afterwards defeated the Russian prince, and spent the latter part of his reign in administering justice throughout his kingdom. By the commencement of the 11th century he had absorbed nearly all the western Slavonic states, including Bohemia. He enjoyed among his subjects the epithet of *Chrobry*, or brave. The Germans, however, in derision of his corpulence, which he endeavored to lessen by hunting, called him *Trinkbier*. To him is due the foundation of the archbishopric of Gniezno (Gnesen), the chief see in Poland.

Towards the end of his life he sought to aggrandize himself at the expense of Russia. He had previously in 1013, according to Thietmar, given his daughter in marriage to Sviatopolk, the nephew of Vladimir. His expedition against Kieff is alluded to by Nestor, but narrated more in detail by Thietmar and Martin Gallus. According to the latter he entered Kieff with the Polovtzi as his auxiliaries, and struck the golden gate with his sword. He was succeeded by Mieczysław his son, who abandoned himself to pleasure and left the kingdom in a disordered state. He is said to have first divided Poland into palatinates, a term which will be explained shortly. On his death an interregnum ensued, and his queen Ryxa, niece of Otho of Germany, held the regency. Owing, however, to the continual feuds between the Slavs and Germans, she was driven out of the kingdom and betook herself to Saxony, whither her son soon followed her. During their absence Poland presented a spectacle of anarchy, the commencement of the long series of miseries of this unhappy country. The serfs are said to have risen everywhere and massacred their lords, and even the priests were not spared. Moreover, two foreign wars, with Bohemia on the one hand and Russia on the other, increased their miseries. The pious Kromer chiefly laments the sacred relics carried off by the ferocious Bohemians which were never restored. To heal the universal wounds it was resolved to send for Kazimierz (Casimir) the son of Mieczysław and Ryxa. But it required some time to find him, for he was hidden in Germany, although the story of his having become a monk in the abbey of Cluny in Burgundy has been shown by Röpell to be groundless. We shall see afterwards that a Polish king did actually seek in a cloister rest from the turbulence of his subjects. Kazimierz married Maria the sister of Yaroslav, the prince of Kieff, who was willing to abjure the Greek faith, and embracing the Latin took the name of Dobrogniewa. By this marriage he became the brother-in-law of Henry I. of France, who had married another sister. This king induced several monks to come from Cluny, and founded two monasteries for them, one near Cracow and the other in Si-

lesia, at this time forming part of the kingdom of Poland. From the earliest period we find the country inundated with foreign ecclesiastics; and to this cause we may probably trace the long use among the Poles of the Latin language. Kazimierz was succeeded by a second Bolesław (1058-1081), of whom many curious stories are told. Bolesław II. In an expedition against Lzaslav, the prince of Kieff, he took that city and remained in it some time with his troops. The stay of Bolesław and his soldiers at Kieff is said to have been attended with the same deleterious effects as befell Hannibal and the Carthaginians at Capua; and the conduct of the Polish ladies during the absence of their lords, unless the chroniclers belie them, cannot be held up as an example to wives. The whole story, however, has a very mythical air.

The most remarkable event, however, of the reign of Bolesław was the murder of St. Stanisław. In this respect he emulated Henry II. of England; he dared to come into collision with the ecclesiastical power, but he did not suggest the assassination of so prominent a person to others; he accomplished the deed with his own hand. His excesses had long drawn upon him the censure of Stanisław, who concluded by putting all the churches of Cracow under an interdict. Upon this the king vowed vengeance on his denunciator. The Polish chroniclers tell us that, on hearing that the saint was to celebrate mass in a chapel, he took with him a few determined followers and hurried to the place. He, however, forbore to break in upon the scene till the service was concluded. This being over, he ordered some of his attendants to enter and slay the prelate. They were restrained, however, by a miracle, for, endeavoring to strike Stanisław to the earth, they all suddenly fell backward. Again and again Bolesław urged them on, and the miracle was repeated a third time, until the king rushed in and with one blow clove the skull of the ecclesiastic. Kromer tells us that immediately after the murder the king and his impious satellites slashed the body, separated it into many pieces, and cast it to be devoured by dogs and birds of prey. It was, however, guarded by eagles who kept off the assailants; and, some monks collecting the remains, they all became mysteriously reunited and were afterwards honorably interred at Cracow. Such a crime was not likely to go unpunished in those days. Gregory VII. (Hildebrand) placed the whole kingdom under an interdict. Bolesław, regarded with hatred by all his subjects, fled into Hungary, but of his end we have no certain information. After the disappearance of Bolesław, who had taken his son with him, the state remained nearly a year without a sovereign. Finally, being afraid of a Russian or Hungarian invasion, the Poles called to the throne Władysław (Ladislav), the brother of Bolesław. Anxious to remove the interdict, he at once despatched ambassadors to the pope; but, although the churches were allowed to be reopened, so great was the authority of the occupant of the chair of St. Peter, who refused again to ratify the title of king, that for two hundred years from this time no Polish ruler could legitimately assume such a dignity, but was obliged to consent to the humbler appellation of duke. Władysław, who was engaged in constant wars with the Russians and the heathen inhabitants of Prussia, died in 1102 at Plock,—as was suspected, of poison. The power of Poland was diminished in his reign, as many provinces were occupied by the Russians. He was succeeded by his son, Bolesław III., to whom the Poles have affixed the surname of Krzywousty, or the Wry-mouthed. Kromer tells us, "Fuit autem Boleslaus hic, habitudine corporis satis firma, vegeta, et laborum patiente, colore fusco, statura mediocri, os ei carbunculus morbus ab ineunte adolescentia distorserat, atque inde Crivousti cognomen habuit." He married Shislava, the daughter of Sviatopolk, the prince of Kieff, and was

successful in many wars, till, having eventually been defeated by the Hungarians on the banks of the Dniester, he is said to have died of grief. He seems to have been a redoubtable warrior, and to have distinguished himself in some very hard fighting. His expeditions against the Pomeranians were characterized by much cruelty, for we are told that Gniewomir, one of their chiefs, was beaten to death in the presence of the Polish army. Besides his attack upon the Pomeranians we learn from Gallus that he also marched against the Prussians, whom he utterly defeated, returning with a large spoil of cattle and other booty. His most important war, however, was with the German emperor Henry V., the husband of Matilda, the daughter of our Henry I. He had probably become jealous of the rising power of Bolesław, for the Germans at that time affected to regard Poland as a fief of the empire. The only event of much interest in this war is the gallant defence of Glogau, where the imperialists were driven off, in spite of their furious onslaught, and were ultimately routed near Breslau. The emperor fled precipitately, and the Poles gave little or no quarter. The field, says Kromer, where the battle took place was full of corpses, and exhibited a sorry and lamentable spectacle. The bodies of the Poles were carefully sought out and interred, but the Germans were unburied and lay as food for dogs and birds. In consequence of this the number of dogs who frequented the spot was so great that the road was rendered difficult to travellers. The place was called the Field of the Dog both by the Poles and Germans, a name which has obtained till the present day. Kromer, however, tells us that some of the German historians claimed the victory for their nation. Whatever the result may have been, peace was soon afterwards made between the emperor and the duke, a peace which was further consolidated by the marriage of Bolesław and his son Władysław to members of the imperial family. Before his death the Polish duke, following the same fatal course which in Russia paved the way for its subjugation by the Mongols, parcelled out his territories to his sons Władysław, Bolesław, Mieczysław, and Henry. There remained a fifth and youngest son, at that time of tender age, Kazimierz. The duke being asked why he had left him portionless is said to have declared that the four-wheeled chariot must have a driver, thus, as it were, prophesying the future pre-eminence of this child. The prediction, which looks very much like a prophecy after the event, reminds us of William the Conqueror distributing his kingdom to his sons. The quarrels of these princes are very tedious. Władysław was ultimately driven out and Bolesław became supreme. His subjects gave him the nickname of Kędzierzawy, or the curly. He was drawn into a contest with the German emperor Frederick Barbarossa, who invaded Poland in the year 1158. It would have been impossible for Bolesław to meet so formidable a foe in the field; he, however, succeeded in forcing him to make peace by continually harassing his army, and laying waste the territory before it. Frederick again attempted to convert Poland into a fief of the German empire, but failed. Bolesław signed a peace by which he consented to give Silesia to his brother Władysław, and the Poles were to furnish three hundred spearmen to assist the emperor Frederick against Milan. An expedition which he undertook against the Prussians in 1167 was unsuccessful; in consequence, as Kromer assures us, of treachery, the Poles became entangled in the marshes of the country and were cut to pieces. On his death Bolesław was succeeded by his brother

Mieczysław
III.

Mieczysław, who was so unpopular that he was expelled from the country in 1177.

The crown, therefore, according to the prophecy, devolved upon Kazimierz, the youngest son of Bolesław Krzywousty. During his reign many judicious laws were passed in Poland; among other improvements he abolished the evil custom of purveyance. His reign

was tranquil, and by summoning a council of the bishops and nobles at Łęczyca he may be said to have instituted the Polish senate, at all events to have laid the foundations of it. At this time the third crusade was preached in Poland, and the order of the Cistercians was introduced into the country. We shall pass rapidly over the reigns of Leszek V. (the White), Władysław III., and another Bolesław. Conrad, duke of Masovia and brother of Leszek, introduced the order of Teutonic knights into the Polish territories on the Baltic, from whom the Prussian monarchy, one of the great enemies of the republic, was afterwards to develop itself. In the reign of Bolesław V. (1227-1279) the Mongols made an incur-
Bolesław V.
sion into Poland, but were subsequently diverted into Hungary, having gained a victory at Lignica (Leignitz) in Silesia in 1241. They carried off great quantities of booty. It is said that on this occasion nine sacks were filled with the ears of the slain. During their stay Bolesław, like Ivan the Terrible at a later period, remained cloistered in a monastery. Lelewel dwells pathetically upon the many evils suffered by Poland during the long reign of this prince, and says he was an unjust judge, a soldier who had aversion to fighting, and a sovereign who neglected the government. At this time also commenced the introduction of Germans into the country in such numbers as to threaten to denationalize it. The trade was almost entirely in their hands, and instead of being governed by Polish laws they enjoyed the benefit of the *Jus Magdeburgicum*. The wide influence of these foreigners is shown by the many words of German origin to be found in the Polish language.

An unfortunate and uninteresting prince, Leszek the Black, succeeded, but the dignity of the house of Piast was fully restored when Przemysław, without condescending to solicit the title of sovereign from the hands of the pope, received the crown from his nobles and clergy at Gniezno (Gnesen). Thus did Poland again become a kingdom. This unfortunate prince, however, was afterwards murdered by the margrave of Brandenburg at Rogozno (1295). The reign of Wacław (Wenceslaus) (1300-5) was not of great importance. He united the crowns of Poland and Bohemia, but soon became unpopular on account of his preference of his Bohemian subjects. Shortly after his election he left the country, and, confiding the control of Poland to the Bohemian garrisons, retreated with his wife to Prague, having been invited to take the crown of Hungary, which he soon abandoned to his son. His death in the year 1305 was accompanied by suspicious circumstances which rendered it probable that it had been brought about by poison. With him expired the race of the holy peasant Přemysl, which had ruled Bohemia according to the ancient chronicles for nearly six hundred years. The relations of the latter country to the German empire were now to become much closer. Władysław Łokietek, who succeeded Wacław, was constantly engaged in wars with the Teutonic knights. In three expeditions against them he allowed his troops to commit great excesses. A full account of them may be found in Kromer, who has given us a florid speech said to have been uttered by Władysław before one of the battles. Several heretics at this time made their appearance in Poland, advocating among other things communistic doctrines. They were severely repressed, and from this time dates the establishment of the Inquisition in the country which lasted till the days of Sigismund I. About 1312 Cracow appears to have been made the capital of the kingdom, and continued so till the reign of Sigismund III.

Władysław was succeeded by his son Kazimierz (Casimir) III., justly surnamed the Great,
Casimir III.
whose reign was a golden period for Poland. The material prosperity of the country increased very much at this time. Commerce was active; the Russians supplied the inhabitants with furs; the southern

parts of Europe sent wines, carpets, silks, cotton, etc. The principal towns of Poland, Dantzic and Cracow, to assist the development of their commerce, joined the Hanseatic league. The towns on the Vistula now began to increase in number and importance, and we first hear of Warsaw, which, however, was not made the capital of the kingdom till the reign of Sigismund III. In 1364 Kazimierz laid the foundation of the university of Cracow, but it was reserved for Queen Jadwiga to carry out his plans. One of the most important events of his reign was the passing of the statute of Wislica (1347). In this legal document the palatines and castellans are mentioned, and the authority possessed by them is carefully defined. It may be well to enumerate here some of the chief functionaries of the republic. The duty of a palatine was to lead the troops of his palatinate on any military expedition, and to preside in the little diets or assemblies of the nobility of his province. Immediately after the palatines came the castellans, who, like the former, were all senators. They were lieutenants of the palatines in time of war, leading the nobility of their jurisdiction into the field, under the command of the palatines. Both the palatines and castellans held judicial tribunals in their respective provinces. The *nuntii* (*postty*) were the deputies returned by the various districts of the palatinates. There were sixteen ecclesiastical senators, including the primate (the archbishop of Gniezno) and the archbishop of Lemberg. They all sat in one house. The *starostas*, employed in collecting the revenue and other functions, had no seat in the house. There are many things in the statute of Wislica favorable to the peasant; thus the power of life and death over him, which his master had previously enjoyed, was abolished. The peasant was not *glebe ascriptus*, and if ill-treated by one lord could move to the estate of another. The inhabitants of the towns, foreign and chiefly German artisans were governed by the *Jus Magdeburgicum*; but appeals to Magdeburg itself were prohibited; for this purpose a Teutonic tribunal was established at Cracow, consisting of a judge properly acquainted with foreign law, and of seven citizens nominated by the *starosta*. Kromer, in his *Polonia*, says, "*Legum scriptarum nullus fuit usus apud Polonos vetustioribus temporibus; nec ulæ extant antiquiores iis quas Cazimirus magnus rex condidit.*" A national diet was now being formed. It consisted of the upper clergy and the nobles, but the inferior clergy and the citizens seem sometimes to have been admitted. Gradually questions of peace and war were introduced and even the election of kings, the principle of departing from the hereditary line being admitted—a concession afterwards attended with great evils to Poland. The improvements of Kazimierz were not confined to law-making; he fortified the chief towns of his kingdom, and built many of their most handsome edifices. He also introduced many artisans from Germany. By his marriage with his first wife Anna Aldona of Lithuania, he had only a daughter. He therefore convoked a diet at Cracow on the 8th May, 1339, in which he proposed as his successor his nephew Louis of Hungary, the son of his sister. This was to concede to the diet a very important privilege, as the throne became virtually elective. The nobles were not slow in availing themselves of the concession which had been made to them. Before they allowed Louis to succeed they exacted some very important terms from him which became the foundation of the celebrated *pacta conventu*. The year after the appointment of a successor his wife died. According to Kromer she was passionately fond of music, and took musicians with her wherever she travelled. The wars of Kazimierz against the hereditary enemies of the country, the Russians, the Lithuanians, and Mongols, were successful. His private life was stained with licentiousness, but his reign marks a distinct epoch in the political and legislative development of the country. With him the glory of

Poland begins, and he is well worthy of the glowing eulogy of the national historian Dlugosz. We cannot wonder also that the Poles dwell with pleasure upon the splendor of the court of Kazimierz, but he certainly squandered the royal treasures too freely. We are told that at one time he entertained at Cracow the emperor of Germany and the kings of Denmark, Hungary and Cyprus. His death was occasioned by a fall from his horse while hunting near Cracow on the 5th November, 1370, and with him expired the line of the Piasts. Casimir was succeeded, Louis. as had been arranged, by Louis of Hungary, who held the crown for twelve years only, and of that period spent but a short time in the country. Louis showed too great a fondness for his own subjects; he had also the misfortune to be unacquainted with the Polish language. After his death his second daughter Jadwiga was elected queen, but Jadwiga. she was to accept as husband any prince whom the diet might propose to her. Her election is declared by Kromer to have been due to the eloquence of one Jan Tenczyn (a member of a celebrated Polish family), whose speech, or an imaginary reproduction of it, is given at great length in very classical Latinity. Jadwiga is said to have been a woman of great beauty and worth. As a matter of state policy she was induced to marry Jagiello, the prince of Lithuania, a man of savage manners; but Lithuania was thus annexed to Poland, with which it remained joined ever afterwards,—a more complete federation having taken place at Lublin in the year 1569. Jagiello was a pagan, but he offered to renounce his creed and to introduce the Christian faith into his dominions; although not educated in that religion he was born of a Christian mother, and its doctrines were not entirely strange to him. The principality of Lithuania at that time stretched from the Baltic to the Black Sea, and eastwards to within a short distance of Moscow. Its religion was Greek Church, and its official language White Russian. The Lithuanian tongue, so interesting to the philologist, seems never to have been anything more than a peasant's language, and no official documents whatever have come down to us in it. This was not the first marriage between the sovereigns of the two countries, as the first wife of Casimir the Great, Anna Aldona, had been a daughter of Gedymin, a Lithuanian prince. Originally Jadwiga felt a repugnance to the marriage with Jagiello on account of the coarse and repulsive manners of the barbarian, and also because she had previously plighted herself to the archduke William of Austria. The matter was referred to her mother Elizabeth of Hungary, who expressed herself favorable to the marriage. The archduke, however, did not abandon his hopes without a struggle: he made his appearance with a splendid retinue at Cracow, but eventually retired on finding that the prosecution of his suit would lead to no favorable result. The new candidate arrived at the metropolis after him, and Jadwiga accepted his proposals. In 1386 they were married, and from that year we may date the commencement of the dynasty of the Jagiello in Poland, which lasted for nearly two centuries, terminating in 1572,—indeed we may say nearly a century longer, omitting the short and brilliant period of Batory (1576–1586), for Sigismund III., was the son of Catherine daughter of Sigismund II., and Wladystaw IV. and John Casimir were his sons; after the death of the latter the throne became entirely elective. The new sovereign was baptized by the name of Wladystaw. Having been converted himself, he forced his subjects to be converted by the simple process which seems to have prevailed over all Slavonic countries. Wladystaw is said have assisted in these pious labors with persuasion as well as command, and by these means Lithuania, which had remained heathen longer than any other part of Europe was finally Christianized. We are told, how-

ever, by travellers of heathen customs remaining long afterwards. Although owing so much to his consort, the king seems to have treated her with jealousy and suspicion. On his impugning her chastity, she insisted on being confronted with her calumniators. The investigation resulted in Jadwiga's triumphant acquittal; and we are told by Długosz that her accuser was compelled in the singular fashion of the country to prostrate himself under a table and declare that he had lied like a dog, and at the same time to imitate the barking of that animal. We are further informed that this punishment for defamation continued in force in Poland until the close of the 18th century. The nobles wrested several important privileges from Władysław; and from this time we can trace step by step the rise of that fierce oligarchy which brought so much trouble upon the unfortunate kingdom. They secured for themselves exemption from all contributions when called to serve beyond the frontiers, and an allowance of five marks for every horseman; they also procured the exclusion of members of the royal family from all the higher offices of the state, reserving these for themselves. In the reign of Władysław many expeditions were undertaken against those inhabitants of Lithuania who preferred to remain pagans. In 1410 also occurred the great battle of Grünwald near Tannenberg in Prussia, in which the Teutonic knights were completely defeated and Ulrich von Jungingen, the grand master, killed. Władysław died in 1434, and was succeeded by his son of the same name. His queen Jadwiga had died in 1399; she appears to have been greatly beloved by the Poles, and was canonized after death—miracles, it is said, being wrought at her intercession. The consolidation of Lithuania with Poland was destined to be a much more tedious and protracted matter than its somewhat violent union. Great as may have been the grief of Władysław at the death of Jadwiga, it did not prevent him from contracting three subsequent marriages—the third wife being Sophia, a princess of Kieff.

The younger Władysław was able soon after his accession to add (by election) both Bohemia and Hungary to his dominions. He then commenced an expedition against the Turks, who under their sultan Amurath II. were pressing the siege of Belgrade, having already annihilated the ill-starred Lazar and his army at the battle of Kossovo in 1389. At first Władysław was everywhere successful, and had instilled such terror into the Turks that Amurath proposed a truce for ten years and offered to cede all his conquests except Bulgaria. The conditions, having been accepted, were ratified by mutual pledges; unfortunately Władysław was induced by Cardinal Cesarini to recommence the war and violate his oaths. The sultan on hearing of this perjury at once prepared for battle at the head of a formidable army. The encounter took place at Varna, in the present principality of Bulgaria. After performing prodigies of valor, Władysław was defeated and slain. Hardly a fifth part of the Polish

Battle of
Varna,
1444.

army escaped from the battle, and of these many perished in the swamps of the Dobrudja. This melancholy engagement, which formed, as the Polish chroniclers tell us, the subject of so many lays—whereof it is a great pity that none have come down to us—is fully described by Kromer (p. 327-8), who adds many omens and pious reflections. He dwells with delight upon the conspiracy of twelve noble captives, who would have murdered Amurath if their plot had not been revealed by a Bulgarian, whereupon they committed suicide. "In necem ejus conjurarunt, peregrissentque facinus præclarum et omnibus seculis memorabile nisi in ipso articulo a Bulgaro, quem unum consilii socium adhibuerant, proditi essent." There is also another curious account in the *Memoirs of a Janissary*, an early Polish work which will be further described in the section devoted to literature.

The memory of the unhappy young prince, who was only in his twenty-first year, was long cherished amongst his countrymen, although, as Kromer tells us, during his short reign he almost drained the treasury and was so busied with the Turkish war that he had but little time to attend to the wants of his Polish subjects. The votaries of Mohammed were now beginning to make themselves a great name in Europe, and were already marching triumphant over the ruins of the effete Eastern empire. The imperial city itself was soon to fall, and the crescent to be placed upon the domes of Saint Sophia.

After a brief interregnum Kazimierz, brother of the deceased king, was chosen to succeed him; he had previously been grand-duke of Lithuania. In this reign the Poles carried on successful wars with the Teutonic knights, which resulted in a peace, by which western Prussia, including Pomerania and the cities Dantzic, Thorn, and others, were to belong to Kazimierz, while eastern Prussia was left to the knights, who were, however, to hold it as a fief of the crown, and each subsequent grand master was to be the vassal (*hotdownik*) of the Polish king and senate. Permanent encroachments were made, however, upon the dominions of the "Republic" (*Rzeczpospolita*) by Ivan III., who reannexed to the Russian crown Novgorod, which had been incorporated by the Lithuanians; he also appropriated a considerable portion of White Russia. The great Muscovite empire was now just becoming welded into a compact whole; with Ivan III. was to commence the era of consolidation, with Ivan IV. that of absolutism. In this reign the nobles first selected nuntii or deputies (*posły*) to attend at the diet, when they themselves were unable to be present in person. They also passed some mischievous laws, aggravating the bondage of the miserable serfs. Previously it was possible for a peasant who had been ill-treated to fly from his lord; now it was enacted that he must be surrendered upon demand, and whoever harbored him incurred severe penalties. The researches of recent Polish historiographers have shown the importance of the reign of this monarch, who may be said to have consolidated the Polish kingdom; from his time the influence of the diet began. The statute of Nieszawa in 1454 has been called as important in Polish law as *Magna Charta* in English; it is the great charter of the rights and privileges of the Polish nobility.

Kazimierz was succeeded by his son John I., surnamed Albert (in Polish, Jan Olbracht), a feeble prince, most of whose wars were ^{John Albert, 1492-1501.} unsuccessful. He led an expedition against Stephen the hospodar of Wallachia, which resulted in a complete defeat. In this reign, at one of the diets (at Piotrkow in 1496—for, as was the case with the parliaments anciently in England, they were held at various places), the nobles decreed that henceforth no burgher or peasant should aspire to any of the higher offices in the church; all such appointments they reserved to themselves. Thus they constituted their clergy a mere aristocratic caste, and imitated the prince-bishops and other spiritual potentates of the Germans. The peasantry were now obliged to bring all their cases before tribunals presided over by their own masters, where they were likely at best to get but a scant measure of justice. Finally, this memorable diet still further limited the power of the king by enacting that none of their sovereigns should in future declare war without their permission. Short as was the reign of John Albert, it saw him involved in many disputes with his nobility. An Italian refugee, Buonacorsi, who had been his tutor, gave him many suggestions with a view to limit the power of the nobility. About the same time, in 1497, some nobles were killed in an unfortunate expedition in Bukowina, and a report was spread that this disaster had been caused by the king himself through the bad counsels of Buonacorsi. In this reign also laws were passed in the diets further

limiting the power of the burghers and the peasantry, who were now forbidden to possess any landed property. John Albert was succeeded by his brother Alexander, an utterly insignificant king; in his reign, however, we trace the first germ of the detestable *liberum veto*, which ruined Poland. In a diet held at Radom it was settled that the decision of the deputies was not to depend upon the majority, but must imply unanimity of suffrages. At a diet in 1652, as we shall afterwards see, it occurred for the first time that a single nuntius annulled by his *liberum veto* the decisions of the whole body present and broke up the assembly. By this absurd custom an element of confusion and disintegration was introduced into all the meetings; it was possible to hire a venal nuntius, for the majority of the Polish nobles seem to have had their price; and as soon as such a man appeared, however important the subjects to be debated might be, he could put an end to all further discussion. The lord high treasurer had the complete control of public finance; he was appointed by the king, but could not be removed. According to the strict letter of the constitution, he must give in his accounts to the diet, but he might easily evade doing so. As the diets only lasted six weeks he might bring them in too late, or if the scrutiny became somewhat tiresome he would probably be able to find a convenient nuntius who would veto the whole proceedings.¹ The story told by Connor of a certain Count Morsztyn, whom we shall find afterwards mentioned among Polish authors, is certainly a very painful one. He says—"I may here give an account of a passage that happened when Count Morsztyn was great treasurer of Poland, who, having more regard to his own private interest than the public benefit, sent all the riches of the treasury into France, when, fearing that the diet would soon think fit to call him to account, he retired privately with all his effects out of the kingdom and went to settle in France, where he purchased the whole county of Château-Villain, which is worth above one hundred thousand livres a year." Such was the corrupt character of the Polish parliament. Other details are given of an equally painful description.² We are told that these meetings rarely happened without bloodshed. A serious fracas occurred among the turbulent nobles—who themselves, while dictating laws, embodied every principle of anarchy—when Sigismund III. was elected. Blood flowed in torrents, and the booths erected for the accommodation of the senators were burnt. At the election of King Michael balls from pistols flew about the tents of the senators, and nuntii were actually killed. Even worse scenes occurred at the election of Augustus II., as will be shown subsequently. In the reign of Alexander we find an instance where a few deputies from the towns were admitted, but their presence was only invited on rare occasions, reminding us how Ivan IV. now and then summoned the Russian citizens to his despotic *douma*: "He was of a middle stature," says Connor, "had a long visage and black hair, was very strong built but exceedingly dull-witted, and consequently but a little talker. He exceeded all his brothers in generosity, and was wont to delight much in musicians and such trifling artists. Nevertheless, this his liberality was generally esteemed but prodigality, inasmuch that some were so bold as to say that he died in time, or else both Poland and Lithuania might have been lavished away. To prevent the like pernicious generosity for the future, the diet made a law, calling it *Statutum Alexandrinum*, by which they revoked all this king's profuse gifts." In the reign of this sovereign the former statutes of Wislica, Warta, Nieszawa, and many others were confirmed and published in a single volume under the superintendence of the chancellor Laski. The feeble Alexander was succeeded by his brother Sigismund (in Polish, Zygmunt)

another son of Kazimierz. Sigismund was engaged in constant wars with Basil, the Czar of Russia; his court was also filled with factions fomented by his wife Bona Sforza, the daughter of the duke of Milan, a woman thoroughly hated in her adopted country, on whom the Poles made the following epigram:

Si parcent Parcæ, si luci lumine lucent,
Si bellum bellum, tum bona Bona fuit.

When she left the country in the reign of her son Sigismund II., she carried large sums of money with her to Italy.

In this reign the order of Teutonic Knights embraced the doctrines of Luther; their dominions were already a fief of the Polish kingdom. Gradually this small principality was to absorb the Slavonic elements which surrounded it, and to rise triumphant over the ruins of Poland. The doctrines of the Reformation were now becoming widely spread over Europe, and the element of religious animosity was largely infused into this land of perpetual anarchy and tumults. Sigismund, however, was a man of remarkable ability, and under his rule the country flourished. He survived to the age of eighty-two, and his memory is still cherished with affection by the Poles. His broad heavy physiognomy may be seen accurately represented in the old editions of Kromer, who dwells much upon his merits. In 1538 occurred the first *rokosz*, as it is termed in Polish, or rebellion of the nobility against the king. The affairs of Wallachia caused Sigismund to undertake a military expedition. Accordingly he appealed to the *rzeczpospolita*, or commonwealth, as the Polish republic was called. One hundred and fifty thousand nobles assembled at Lemberg, but instead of marching to the war they laid their complaints before the king and refused to serve, and the old man was obliged to put them off with promises. The Lithuanians had not yet become reconciled to their union with Poland, even after so long a time, and one of their chief men, Glinski, taking advantage of this feeling, attempted to restore its former independence to the country. Sigismund, however, succeeded in defeating Glinski, who fled to Russia. He then persuaded the grand-duke to invade Lithuania, and assisted him in getting possession of Smolensk in 1514. Sigismund made a treaty with the grand-duke, but he did not succeed in getting back Smolensk. In 1526, by the death of the last of the dukes of Masowsze (Masovia), this duchy was reunited to the crown of Poland. In 1533 Sigismund concluded a treaty with the Turks, then at the height of their power. This peace guaranteed to Poland the free navigation of the Black Sea, with the sovereignty of Moldavia, and prevented the irruption of the Mongols into Podolia, where they were in the habit of committing great excesses, as the Little-Russian national ballads pathetically tell us. The reign of Sigismund was a period of great peace for Poland, and we may truly say that its glory at this time culminated. It seems a rule that the great men of a country are produced at periods of national prosperity, so we now find Copernicus flourishing, the one man of genius produced by Poland whose glory has resounded throughout the world. In 1529 Sigismund published his code of laws for Lithuania, which was issued in the White-Russian language, and forms one of the most important monuments of Polish law.

He was succeeded by his son Sigismund II. (1548–72), otherwise called Sigismund Augustus, but this prince was not elected till a very stormy debate had ensued as to whether he should repudiate his wife or not. He had married, as a widower (his first wife having been Elizabeth, daughter of Ferdinand of Austria), a fair widow of the house of Radziwiłł one of the most illustrious of the families of Lithuania. The nobles, however, who already treated their sovereign as a chief magistrate and nothing more, and had begun to control all his movements, required at the diet of

Sigismund
I. (1507–
49).

¹ See *Letters concerning the Present State of Poland*, 1773, p. 37.

² *Ibid.*, p. 27.

Piotrkow that the marriage should be annulled, merely on the grounds that the country would gain more by his alliance with the daughter of a foreign potentate. But Sigismund, by sowing discord in the ranks of his opponents—proposing among other things to destroy pluralities in church and state—contrived to carry his point. His wife was crowned 1550, but died within six months after, not without suspicions of having been poisoned by her mother-in-law. She is said to have made herself universally beloved during the short period in which the Poles had beheld her as queen. In three years' time Sigismund married a third wife, the sister of the first, and widow of Francis Gonzaga, duke of Mantua. During this reign the quarrels between Protestants and Romanists raged fiercely in Poland, and the latter were very severe in their persecutions. A priest was burnt to death for administering the sacrament in both kinds, and a lady suffered the same terrible fate for denying the real presence. Many of the nobles were infected with the new teaching, but Sigismund was disingenuous and inconsistent in his conduct. He is himself supposed to have been inclined to the doctrines of the Reformation; he certainly permitted Calvin to dedicate to him a commentary on one of the epistles of Paul, and Luther an edition of his German Bible. Finally, realizing that the majority of his subjects were Catholics, he abandoned a faith to which he had perhaps given but a half-hearted adherence, and allowed the bishops to suppress with severity all promulgation of the new doctrines.

The religious question was keenly debated in a diet held at Wola near Warsaw the year after the death of Sigismund. It was resolved not to allow the sword to settle any religious differences. According to the language then used there was to be universal toleration. We shall soon see how little this was carried out. We find from it that the Polish peers were supposed to be masters of the spiritual as well as the material condition of their serfs, for it was expressly stated that their power over them was to be unlimited, "tam in sæcularibus quam in spiritualibus."

In his wars with Ivan the Terrible, in which the subject of quarrel was the Baltic provinces, Sigismund was not very fortunate; he was not able to prevent the Russians from acquiring the palatinate of Polotsk, nor could he subsequently hinder the Swedes from making themselves masters of Livonia. He died in 1572, leaving no issue by his three wives; and with him became extinct the race of the Jagiello, the second great family which had ruled over Poland. His reign was very favorable to the development of Polish literature. Then, too, the laws were first authoritatively promulgated in the native language, which was spoken at court, although Latin continued to be extensively employed. During the reign of Sigismund Augustus, Poland reached the height of outward prosperity. It included Lithuania and western Prussia, and by the addition of Masovia and Livonia extended its limits from the Baltic to the Black Sea, and almost from the Oder to the Don. The seeds of disintegration, however, had long been sown; since the marriage of Jadwiga with Władysław Jagiełło the crown of Poland had been more or less elective, although it continued in the same family. One important event which marked this

Diet of
Lublin.

reign must not be forgotten; in 1569 took place the celebrated diet of Lublin. By this a close union was effected between Poland and Lithuania, which up to this time had been ill united, and indeed there were continual jealousies breaking out during the existence of Poland as a nation—two great points being the difference of religion and language. Even the union of Lublin was not effected without considerable resistance. The following were its conditions:—Lithuania gives Podlasie to Poland; Livonia, under the title of duchy, belongs equally to the two states; Volhynia and the duchy of Kieff—that is to say, the Ukraine—are incorporated with Poland; the kingdom of Poland and the grand-duchy

of Lithuania are to form a single indivisible republic, and are to have a single head, elected by their common votes; the senate is to be composed of nobles of both nationalities. Warsaw was fixed upon as the seat of the diet, since, being part of Masovia (Masowsze), it was, strictly speaking, neither Polish nor Lithuanian. It afterwards became the regular capital of the country in the reign of Sigismund III.; as we have seen, the first two capitals of Poland were Gniezno (Gnesen) and Cracow. Warsaw is of comparatively late origin. It is said to have been founded by Conrad, the duke of Masovia, in 1269. The old dukes of Masovia resided at Czersk near Warsaw, of which some of the ruins might be seen one hundred and fifty years ago (C. H. Erdtel, *Warsavia physice illustrata*, Dresden, 1730). The city is most advantageously situated, and with a better railway system and fewer fiscal restrictions would be one of the greatest emporiums in Europe. An interregnum now occurred on the failure of the line of the Jagiello, and the throne was publicly offered for competition. Four candidates appeared:—Ernest, archduke of Austria; Henry of Valois, duke of Anjou, brother of the French king; a Swedish prince; and finally Ivan the Terrible of Russia. The contest, however, really lay between the first two; the Swedish alliance was despised as likely to bring with it no solid advantage; the czar was hated both as coming from a race which had ever been hostile to Poland, and also on account of his detestable cruelties, which were well-known throughout Europe. The political importance of France and the astute diplomacy of Montluc, the ambassador from that country, caused the decision to be given in favor of the French candidate. But, just as his name was brought

Henry.

forward as their probable king, the Poles, many of whom, we must remember, had embraced the Reformed doctrines, were startled by the news of the massacre of St. Bartholomew (August 24, 1572). From the awkward dilemma in which he was placed by his complicity in this act, Henry endeavored to escape by a falsehood,—impudently denying at first that anything of the sort had happened. Finding, however, but little credence given to his assertions, he attempted to explain away the affair and to lower the number of its victims, which he reduced to fifty, alleging that they had been really executed for a conspiracy. The Polish ambassadors duly made their appearance in Paris, showing their gay equipments, quaint and semi-Asiatic; their bows and arrows and shaven crowns with a single tuft of hair greatly amused the inquisitive French. Loose flowing robes, high boots, and a sword resembling a scimitar completed the *tout ensemble* of a Polish nobleman.¹

Readers of French history must be well acquainted with the character of this duke of Anjou, one of the most detestable of the house of Valois, who afterwards became king of France under the title of Henry III. The articles, some of which the Polish nobles required Henry to sign, called the *pacta conventa* so well illustrate the extraordinary influence of the aristocracy, and the shadow to which they had reduced the regal authority, that they are worth quoting *in extenso*. From this time every Polish king was compelled to accept them, together with the additions subsequently made.

Pacta
conventa.

(1) The king was to have no voice in the election of his successor; the appointment was to depend entirely upon the nobles.² (2) He was to keep rigidly the terms of the treaty made with the Dissidents, as the Polish Protestants

¹ The Poles regarded the national dress with peculiar fondness, and Coxe tells us that they were somewhat indignant with their last king, Stanislaus August Poniatowski, 1764-95), because he always appeared with flowing hair and adopted a French style of dress. They even meditated introducing a new clause into the *pacta conventa*, requiring that every king of Poland must wear the Polish dress.

² We shall find, however, this rule sometimes infringed, and instances occur in which the opinion of a sovereign affected the next nominee. Thus the malicious wife of Sobieski was able to exclude her son James from the succession to which the national voice had almost called him.

were called. (3) No war was to be declared nor military expedition undertaken without the consent of the diet. (4) No taxes were to be imposed without the consent of the diet. (5) The king was not to appoint ambassadors to foreign courts. (6) If different opinions prevailed among the members of the diet, the king was to adopt only such as were in accordance with the laws or advantageous to the nation. (7) The sovereign must have a permanent council, consisting of five bishops, four palatines, and eight castellans, who were to be changed every year and elected by the diet. (8) A general diet was to be convoked every two years, or oftener, if there were any need. The assembling of these diets seems to have depended upon the will of the king. (9) The duration of each diet was not to exceed six weeks.¹ (10) None but a native could hold any dignity or benefice. (11) The king must neither marry nor divorce a wife without the consent of the diet.

Thus the regal shadow who was to sit upon the throne of Poland was able to interfere but little in questions either of peace or war. The latter, we have seen, he could not declare; and, as each of the palatines held nearly supreme power in his own territories, the king could interfere in little relating to the former. A vexatious control was exercised even over his private relations; his wife could not be of his own choosing, and, however odious she might become to him, she must remain attached as a state appendage till his nobles consented to release him. Not that Henry was likely to trouble himself with any scruples on the score of marriage. He arranged all those matters very easily. What was left for the Polish king was chiefly to eat and drink at the expense of his subjects, and to form a glittering addition to their costly and semi-barbarous pageants. Still his revenue was ample, and when he commanded the army in the field his power was unchecked; he had also the nomination to the highest ecclesiastical and military appointments.

Even before the severe terms of the *pacta conventa* had been presented to Henry, Montluc had agreed to all, but probably felt convinced that his sovereign would carry out no more of them than he could possibly help. He even promised that France should send a fleet into the Baltic, so that its dominion might be secured to the Poles, and that in the event of a war with Russia she should supply four thousand of her best troops, and herself pay their expenses; in all cases of war she was to aid Poland with money. Henry was to spend a large portion of the rents which he drew from his estates in France for the benefit of his adopted country; he was also to pay the crown debts, and to educate one hundred young Polish nobles either at Paris or Cracow. Probably no sovereign in the world ever signed such galling stipulations. Henry, however, had no intention of observing them, and had so little relish for his new kingdom that he did not set out till he had almost been driven from France by his brother, and the Polish nobles already talked of a new election. He proceeded on his way slowly, with all the dignity of a royal progress, but did not escape the gibes of the German princes through whose dominions he passed, for his connection with the massacre of St. Bartholomew. He was feasted at Heidelberg opposite a large picture which delineated the tragedy in all its horrors, and attendants were allotted him selected from French Huguenot refugees. He was crowned at Cracow in February 1574, but soon began to repent of his choice. The effeminate king relished but little the throne he had chosen among a warlike and turbulent people, where he seemed to enjoy but the shadow of a sovereignty—a people also in every way inferior in civilization to the agreeable Parisians he had left behind. He felt himself a mere puppet in their hands, and, burying himself in the recesses of his palace, led a life of dissipation. But release was at hand in an unexpected

way; he was destined to be king of Poland for five months only. By the death of his brother Charles IX. he became heir to the French crown. This delightful piece of news he attempted at first to conceal, and to escape before it could get noised abroad in Poland, principally to avoid the ambitious designs of his brother, the duke of Alençon; but unfortunately the report oozed out. He refused to follow the counsel of his advisers that he should convoke a general diet to see what measures should be taken. On the evening of the 18th July he gave a grand entertainment in honor of the sister of the late king Sigismund. The conviviality was great; and never had Henry assumed a more pleasing manner or seemed more genially to identify himself with his new subjects. At the usual hour, to all appearance, he retired to his apartment and the lights were extinguished: but already the king had flown. He was led by an attendant through secret passages to a chapel in the suburbs of the city, as some say—but according to more probable account to the royal stables, where a rendezvous had been appointed. Here horses had been prepared; and with a few chosen attendants he rode precipitately from his kingdom, reaching the frontiers of Silesia early on the following day. Great was the consternation in Cracow when it was known that he had fled, and hot the pursuit of the authorities. The probability of the king's flight, gathered perhaps from his ill-concealed uneasiness, had caused it to be suspected before it was known as an actual fact. The grand chamberlain, anxious to calm the universal excitement, returned to the palace to which by virtue of his office he had general access. At first he knocked at the king's door, but no answer was forthcoming; he then tried the chambers of the gentlemen-in-waiting; there equally he found a dead silence. Again, he returned to the king's bedroom, and, not being able to force the door, entered by the window—for even in matters of etiquette they seem in Poland to have treated their kings somewhat roughly. The candles were burning as usual in the room; the two pages were near the bed; the curtains of the bed were drawn, but there was no Henry to be found. The grand chamberlain, amazed, rushed in pursuit, attended by five hundred cavaliers. Probably such a ludicrous sight had never been seen before as a monarch flying from his kingdom and subjects without being driven out by them. Owing to his ignorance of the route the horsemen were soon on his track, and many of his companions, to save themselves, deserted him. One of them named Pibrac hid himself in a bog, and was even obliged to make several dives to escape the infuriated peasants, who pelted him with stones, unconscious of what he had done, but satisfied from his efforts at concealment, that he must be flying from justice. In vain did Henry cause the bridges to be broken down behind him; the Slavs on his track forded the rivers on horseback, and the king was at last overtaken on the very boundaries of the German empire. There Tenczyn, the grand chamberlain, and five horsemen came up with the fugitives and shouted after the king "Serenissima Majestas, cur fugis?" Finding that he was quite safe Henry admitted Tenczyn to an audience, who remonstrated with him on account of the manner in which he was leaving the kingdom, and recommended him to return and convoke a diet so that with the consent of his subjects he might take possession of his new kingdom. But he refused to be influenced by their entreaties, and merely promised in a vague manner that he would return as soon as he had placed France in a state of tranquility—a promise which it need hardly be said, he had no intention whatever of carrying out. Nor did the king show any special alacrity in repairing to France, for before reaching that country he lingered a considerable time at Vienna and Venice, trifling with the highest interests of his country, and devoted only to frivolous amusement. The Poles, however, were well rid of one of the most corrupt

¹ We shall afterwards see that this mischievous law was fruitful of evil consequences to the country, as frequently debates upon the most important questions would be brought to an end by the interference of one of the nuntii declaring that the legitimate six weeks had elapsed.

sovereigns of a corrupt house. In 1589 the knife of the Dominican friar terminated his life, and with it the line of the Valois.

The Poles, piqued at the contempt with which their crown had been treated, assembled at Stezyca and resolved to declare the throne vacant if the king did not return by the 12th May, 1575. During the interregnum the Mongols made incursions into Podolia and Volhynia, and grievously devastated those countries. The appointed period having elapsed, Stephen Batory, prince of Transylvania, was elected, having previously stipulated to marry the princess Anne, sister of Sigismund Augustus. There were some difficulties, however before he succeeded in obtaining the royal authority. The prime Ucharski nominated the emperor Maximilian king. This caused considerable opposition, and the city of Dantzic did not recognize the new sovereign till compelled. To conciliate the nobility Batory was obliged to consent to some serious diminutions of the royal prerogative. This king was a great soldier, successful against both Prussians and Russians, the latter of whom he compelled, in 1582, to evacuate Livonia, which was thus again annexed to Poland. He also did much to encourage letters, having founded the university of Vilna, which has, however, been suppressed in more recent times. His great fondness for the Latin language is said by Schafarik to have had a bad effect upon Polish; for from this time may be dated the classical words and idioms which have been thrust upon the language, and have disfigured Polish more than her Slavonic sisters. It was Stephen Batory who first organized the regiments of Cossacks who play such an important part in Polish history. Before his death, foreseeing the constant anarchy which the system of elective sovereignty would cause, he in vain urged the nobility to make the crown hereditary. Sarnicki, the Polish historian, says of him—"Fuit vir tam in pace quam in bello excelso et forti animo, judicii magni, præsertim ubi ab affectibus liber erat; in victu et amictu parvus, et omni jactantia et ostentatione alienus, eruditio insigniter tinctus, sermonis Latini valde studiosus et prorsus Terentianus." It would naturally be concluded that before the election of Batory the royal power had been sufficiently curtailed, but it was to undergo further mutilations. Sixteen senators were now chosen at each diet to attend the king and give their opinion in important matters, and no decree could be issued without their consent. Besides this, in 1578 the right of final appeal to the king, which had always been a royal prerogative, was taken away. The king could now only give the ultimate decision in a small district within a certain radius of his residence. The courts exercising judgments within these narrow limits were called *Assessoria Regni*, and even these judicial powers, slight as they were, were gradually abandoned after the time of Augustus II., and were exercised by the high chancellor of the realm. The king was supposed to have some control of the courts which were governed by the *Jus Magdeburgicum*; but, Batory being busy with foreign wars, these were generally managed by the chancellor also. The palatines had the right of electing their own judges in their dietines or petty diets, who formed supreme courts of justice called *Tribunalia Regni*; here the causes of the nobles, for the peasants had no voice in the matter, were decided finally and without option of any appeal.

On the death of Batory in 1586, after many quarrels among the leading families, the throne was again brought into the market. The candidates were, among others, the archduke Maximilian of Austria; Feodore Ivanovich, the feeble Russian czar; and Sigismund, a Swedish prince, son of Catherine, sister of Sigismund Augustus. The last of the three was finally elected, although not without considerable opposition from Maximilian, who was only driven from his candidature by main force. The Zborowskis a very powerful

family always in opposition to Zamoiski, the chancellor of the kingdom, invited him. But Zamoiski defeated him at Byczyna in Silesia, and he was there made prisoner, and was only released on the promise of desisting from being a candidate. The Austrians, however, were always interfering in the affairs of Poland, and, if they could not procure the admission of any of their family to the headship of the republic, we shall observe that during four generations the house of Hapsburg furnished queens to Poland. A very serious riot occurred at the election on this occasion, as Lengnich tell us in his *Jus Publicum Regni Poloni*; the booths erected for the senators were burned to the ground. Such proceedings were only to be expected in a country where each noble might keep as many armed retainers as he pleased.

The new king signed the *pacta conventa*, and an alliance offensive and defensive between Poland and Sweden; the navigation of the Baltic was secured, and the debts of the nation were to be discharged. Sigismund, however, soon became unpopular among his new subjects, and among other causes of offence he violated the *pacta conventa* by marrying an Austrian princess, Anne, daughter of the archduke Charles, without their consent. In 1595, at Brześć in Lithuania, took place the so-called union of the Greek and Latin Churches, but this union was not brought about without considerable violence. The disputes between the king and the diet were destined to be renewed when (his wife being dead) he married her sister Constantia in 1605. This union was also entered into without the consent of his subjects, and caused the cup of their wrath, already full, to overflow. On this occasion Jan Zamoiski, the chancellor already mentioned, addressed a vehement oration to the king, which is quoted at full length by Lelewel, in which he brought his marriage against him among many other charges. When Zamoiski had finished, Sigismund rose from his throne in a moment of anger and seized his sword. At this gesture a murmur of indignation ran through the diet, and Zamoiski cried in the midst of the crowd, "Rex, ne move gladium; ne te Caium Casarem, nos Brutus sera posteritas loquatur. Sumus electores regum, destructores tyrannorum; regna, sed ne impera." A great *rokosz* or secession, as the phrase was in Polish, was the result of this. But the rebels wanted able leaders, and the king defeated them at Guzow, near Radom, on the 6th July, 1607, and thus his throne, already tottering, seemed to become a little stronger. He pardoned the insurgents; and the country, on the verge of civil war, seemed pacified; but the rebellion was a fatal precedent. The most important events in this reign were the transactions which took place between Poland and Russia. The renegade monk Otrepieff personated the young Dmitri of Russia, who had been assassinated, probably by the orders of Boris Godounoff, and aspired to seat himself upon the throne of the czars. This wonderful plot was concocted at Cracow, and seems to have been a plan of the Jesuits to bring over the Russians to the Latin Church.¹ In 1606 the pretender was killed in a tumult, and many of the Poles who had accompanied him to Moscow were murdered. In 1617 Sigismund sent his son Władysław to Moscow, which had been taken by the Polish general Zolkiewski. Władysław was elected czar by a certain faction; but the Russians, disliking to have a heretic for their emperor, rose against the newly appointed sovereign; and the patriotism which was lacking to the boyars was found in the unselfish devotion of a provincial butcher. Russia was freed, and a new dynasty was established in the person of Michael Romanoff. Sigismund had many wars with the Turks, which led to no very important results; the great victory, however, of Chodkiewicz at Khotin (September 28, 1622) has become ever memorable in

¹ See however, *Rome et Demetrius*, by A. P. Pierling, S. J. (Paris, 1878), for the contrary view.

Polish annals, and has formed the subject of several poems. Lengnich, in his *Jus Publicum Regni Poloni*, tells us that in 1632 the Cossacks petitioned to be allowed to take part in the diets. Their request was refused in an insulting manner; and the Poles had soon to pay dear for their insolence. Sigismund died in 1632; his statue still ornaments the city of Warsaw, which he made the capital in the place of Cracow. He was unceasing in his efforts to extirpate Protestantism from his dominions.

The luxury of the nobles at this period has been described at great length by Lelewel. He has also much to tell us about the small armies of retainers kept up by the Poles, which it is a pity there was no statute of maintenance, as in England, to check. These private troops, however much bravery they may have occasionally shown, prevented all unity of action. The reign of Sigismund III. was on many grounds a disastrous one for Poland, and it was a very long one. There were constant military revolts and religious tumults. The king and his Austrian wife were so foolish as to be partly drawn into the Thirty Years' War. They thought that, supported by the emperor and the king of Spain, they might be able to regain the crown of Sweden. They therefore permitted the emperor to enrol troops in Poland, and even sent him some regiments of Cossacks; they also got ready a fleet in the Baltic—strange as it may seem to hear of Poland as a naval power. All these plans, however, ended miserably. By the treaty of Malborg (Marienburg), in 1623, Sweden gained Livonia, Elbing, and part of Prussia.

He was succeeded by his son Wladystaw IV., who was elected by the diet. During his reign the usual wars took place with the ancient enemies of the republic,—the Swedes, Russians, and Turks. Before its close the revolt of Bogdan Chmielnicki had broken out, which cost Poland her Cossack subjects, who had been so happily gained over by the more vigorous policy of Batory. The Zaporogians, or Cossacks of the Dnieper, now transferred their allegiance to Alexis of Russia. They had long felt uncomfortable under the Polish government owing to the proselytizing tendencies of the bigoted Sigismund III. Fresh alarms were caused by the erection of the fortress of Kudak on the Dnieper, and they broke out into open rebellion. In 1638 they were deprived of the right of having a hetman; and Pawluk, their chief, was decapitated in spite of an express promise that his life should be spared. Wladystaw was in constant collision with his nobles. He fretted under the restrictions placed upon his power, and attempted to carry on wars without the consent of the diet. But the nobles compelled him to break all his engagements. He died at Merez in Lithuania, between Grodno and Vilna, May 20, 1648, and was succeeded by his brother John Casimir (Jan Kazimierz), the other candidates being the czar Alexis, father of Peter the Great, and Ragotzi, prince of Transylvania. One of the first acts of the new king was to endeavor to negotiate with Bogdan, but the negotiations were brought to an abrupt termination by the treachery of Wisniowiecki, the Polish general, who fell upon the unsuspecting Cossacks while they were deliberating about the terms of the convention. After this massacre Bogdan raised another army, but was completely defeated by John Casimir at Beresteczko in 1651. The kingdom, however, was thrown into the greatest confusion by the disputes of the nobles, and all vigorous action was paralyzed. The blood-stained annals of these wars are full of horrors: the population in many districts was entirely extirpated; everywhere murder and plunder were rampant; and tortures too horrible to mention were inflicted upon the unhappy prisoners.

At a diet held in 1652 a single nuntius for the first time annulled by his *liberum veto* the united resolutions of the whole assembly,—Siciński,

from Upita in Lithuania, stopping the diet with the simple word "niepozwalam" (I forbid). As soon as he had uttered this ominous protest he quitted the assembly. Those who were present were puzzled as to what construction they ought to put upon such a proceeding, but Siciński had not acted without confederates on whom he could rely. An angry debate ensued, but the principle was finally carried by a majority and firmly established. Ruptures of this kind became more frequent, as Lelewel tells us, and the queen Louise Marie, who had great influence over the king, frequently made use of them. Lengnich, in his *Jus Publicum Regni Poloni* (1742), enumerates thirteen occasions on which this baleful practice had broken up the diet. It was not finally abolished till 1791. The reasons why it was popular have already been spoken of. Among other causes may be mentioned the anxiety of the great officers of the realm—the commander-in-chief, treasurer, marshal, and others—to be free from the control of the diet. These important functionaries held their appointments for life, and were under no supervision during the intervals between the sessions of the diet. Again, it was only before the diet that a noble accused of capital crimes could be brought to trial, for the nobility exercised, as has already been said, supreme judicial powers in their own palatinates. If, therefore, as was frequently the case, a criminal of this rank happened to be brought forward, it was very convenient for him to be able to procure a dissolution of the only tribunal by which he could be convicted. Again, it was an admirable way to oppose the levying of taxes, which could only be raised by the consent of the diet; and taxes, owing to the constant wars in which she was engaged, were very heavy in Poland. There were emissaries of foreign powers, too, who fomented these internal discords and profited by fomenting them.

The ill effects of the *liberum veto* soon began to be felt. In 1670 the members of the diet bound themselves by an oath not to make use of the privilege. In spite, however, of this resolution that very diet was brought to an end by the appeal of Zabokrzycki, the nuntius from Braclaw in Podolia. In 1667, by the treaty of Andruszowo, Poland lost to Russia Smolensk, Vitebsk, Polotsk, and other towns, the Dnieper now becoming the boundary; Kieff, the interesting old historical city, was to go two years later. In the midst of all these misfortunes the exhausted country was attacked by a new enemy, Sweden, in consequence of the Polish monarch asserting a right to the Swedish crown, as the heir of the house of Vasa—a claim which he had no possibility of enforcing. Hampered as he was by a war with Russia, John could effect nothing against his new enemies, who took both Warsaw and Cracow, and ended by entirely subjugating the country, while the wretched king fled to Silesia. Although these new enemies were afterwards expelled, yet the war was protracted for some years, and ended disastrously for Poland. Charles Gustavus, the Swedish king, is said to have proposed the partition of the country; he offered Great Poland to the elector of Brandenburg, Little Poland to the duke of Transylvania, and a part of Lithuania to a Polish nobleman named Radziwiłł. But Poland's hour had not yet come. The elector of Brandenburg procured the release of East Prussia from all seigniorial rights in 1657. Livonia was also another loss, having been ceded to Sweden in 1660. An army of Cossacks and Mongols, which had invaded Podolia, was defeated by the celebrated John Sobieski, who now first appears in history and was made commander-in-chief of the Polish troops. Worn out with age, and disgusted with his repeated failures, the king abdicated in 1668. At a previous diet he had warned his turbulent subjects that the partition of the kingdom must be the inevitable consequence of their dissensions. John Casimir had already been an ecclesiastic; he had been absolved from his vows by the

zowo.

pope when he became a candidate for the throne. He now resolved to betake himself again to the cloister,—his wife, Louise Marie, daughter of the duke of Nevers, a woman of beauty and spirit, being dead. He took his leave of the Poles in an affectionate and dignified address, which is still preserved, and has been pronounced by Coxe to be “the finest piece of pathetic eloquence that history has ever recorded.” There was something very touching in the fact that Jan Kazimierz represented the last of the Jagiello and Vasas, the former of whom had so long ruled over Poland. He was son, as previously mentioned, of Sigismund III., and great-grandson of Sigismund I., whose daughter Catherine had married John, king of Sweden. Connor says: “While I was at Warsaw I spoke with several old gentlemen, who told me that Casimir, the day after his resignation, observing the people hardly paid him the respect due to a gentleman, much less to a king, seemed to have repeated heartily of the folly he had committed” (i. 135). He now returned to France, a country in which some years previously he had suffered a strange captivity, having been detained in the reign of Louis XIII. while passing its coasts; but the story is too long to be narrated in these pages. Here he became abbé of St. Germain and St. Martin, and drew his means of subsistence from these ecclesiastical foundations; for the Poles, although to all appearance abundantly moved by his melancholy rhetoric, refused to continue his pension. Nor does he appear to have spent the short remainder of his life entirely in the cloister, as we are told that he contracted a secret marriage with an amiable widow who had formerly been a laundress. He, however, survived only four years, dying in 1672, forgotten by the world but not forgetting it,—his disease, according to some accounts, being greatly aggravated by his receiving the intelligence that Kamenets in Podolia had been ceded to the Turks. His body was afterwards brought to Cracow and buried in the cathedral. The diet, which met on his abdication, passed a decree that for the future no Polish king should be allowed to abdicate. During this reign, in the year 1658, the Socinians were banished from Poland, in consequence of which Pope Alexander II. gave to the king and his successors on the Polish throne the title *Rex Orthodoxus*. In due time three candidates for the vacant throne made their appearance—the prince of Condé, the prince of Neuburg, supported by Louis XIV., and Charles of Lorraine, who was put forward by Austria. The first of these could rely upon the coöperation of the great Sobieski, but eventually none of the three was chosen. The election fell upon a native Pole—Prince Michael

Michael
Wiśniowiecki
(1669-73).

Korybut Wiśniowiecki, of a noble family indeed, but so impoverished that he may be said to have had regal honors thrust upon him against his will, and we are even told that he was offered the crown half in derision. A graphic picture of this extraordinary scene is given in Pasek's contemporary memoirs. Michael soon became a mere puppet in the hands of his turbulent subjects. His reign, however, was rendered illustrious by the great successes of Sobieski against the Turks, although the Poles suffered the loss of the important town of Kamenets, and Michael, powerless to make head against them, concluded the treaty of Buczacz, by which he even stipulated to pay them tribute. By the great victory of Khotin in 1673, Sobieski did much to repair these losses, and was about to follow up his glorious campaign when he heard of the death of Wiśniowiecki at Lemberg in Galicia; so sudden was the end of Michael that some have even supposed that he was poisoned,—“by a Frenchman,” says Connor. The diet met at Warsaw; there were several candidates, and among others Charles of Lorraine and Philip of Neuburg again put forward their claims. While the nobles were still in session, Sobieski, fresh from his glorious victory, entered and pro-

posed the prince of Condé. A stormy discussion ensued, and in the midst of it one of the nobles, Jablonowski, was heard to say, “Let a Pole rule over Poland.” The cry found a magic echo among those who were present, and the gallant Sobieski, the greatest of Polish generals, and one of the first soldiers of his time, was appointed king under the title of John III., although not without considerable opposition from Michael Pac, the general-in-chief of Lithuania, who was, however, ultimately induced to withdraw his protest. This king signed the same *pacta conventa* as the preceding monarchs; there was, however, a trifling addition made to them, but that a very absurd one. To the article declaring that offices should only be conferred on native nobles it was added, “and on such only as have had their honours during three generations.” The leading idea of Sobieski was to drive the Turks out of Europe, and if possible to resuscitate the Byzantine empire. He was soon roused to action by a new invasion of the Turks and Mongols, whose united armies are said to have amounted to 210,000 men,¹ commanded by the Seraskier Ibrahim, whose ferocious character was sufficiently indicated by his soubriquet, Shaitan or Devil. We are told that Sobieski had only 10,000 men to oppose to this vast host; he, however, set out from Lemberg, and was soon hemmed in by his adversaries at Zurawno, in Galicia, but by consummate bravery and adroitness succeeded in rescuing himself and his soldiers, even concluding a treaty with the Porte on favorable terms, by which Poland received back a part of the Ukraine and Podolia.

Some years of peace followed, during which the king in vain endeavored to raise supplies for an army to reconquer the provinces which Russia had appropriated. All his plans were neutralized by the absurd practice of the *liberum veto*. In 1683 the Turks made their grand invasion which they had long been preparing. After scouring the plains of Hungary, they advanced to the very walls of Vienna. The emperor Leopold at once fled with his court, but had great difficulty to avoid falling into the hands of the Mongols. The imperial party made no stay till it reached the Bavarian fortress of Passau. Quick in its track followed also the wealthier portion of the inhabitants; their selfish desertion aroused murmurs of disapprobation, and also considerably thinned the number of the population capable of bearing arms; many of these fugitives fell into the hands of the invaders, who were capable of any cruelty. The command of the city was taken by Count Starhemberg; he had already approved himself a brave soldier, and had been nominated to the post by the emperor. All classes at once—including even priests and women—labored diligently at the fortifications, the burgomaster Von Liebenberg himself setting an excellent example. The imperial archives had already been removed; nothing now remained for the devoted city but to await the approach of the enemy. The inhabitants could see the desolated villages, and the fire and smoke of the burning cottages were conspicuous for miles around. At sunrise on July 14, the vast hordes of the invaders, a promiscuous crowd of soldiers, camp-followers, camels, and baggage-wagons made their appearance. The camp was arranged in the form of a crescent; splendid above all other things was the tent of the vizier, Kara Mustapha, made of green silk, worked with gold and silver, set with precious stones, and containing inside the holy standard of the prophet. Marvellous stories are told of the fountains, baths, gardens, and all the appliances of Oriental luxury which it contained. Many painful incidents characterized the siege before the arrival of Sobieski; a fire at one time broke out in the city, which was only suppressed with difficulty.

¹ 80,000 Turks and 130,000 Mongols, as we are told by the Polish historians.

Siege of
Vienna
(1683).

Diseases raged among the townspeople owing to their being compelled to spend their days in such close quarters and to live chiefly upon salt meat. Relief, however, was rapidly approaching. The elector of Saxony, John George, marched out of Dresden on the 22d July with twelve thousand men and eighteen guns, and reached Krems on the 28th August. The Polish king, who had been solicited by the emperor himself, and to whom all Europe looked now as its saviour, left Cracow accompanied by his son, and succeeded in reaching the quarters of Prince Charles of Lorraine. He was to act in concert with a man who had been competitor with him for the Polish crown; their meeting passed off amicably, and no subsequent jealousies seem to have marred their operations. The Polish and German troops effected their junction at Krems on the Danube, near Vienna; there were about seventy-seven thousand men ready for active operations in the field. On the 12th September, after mass, Sobieski descended from the city to encounter the dense masses of the Moslems in the plains below. He appeared with his hair partly shaven in the Polish fashion, and, although plainly attired himself, was accompanied by a brilliant retinue. In front went an attendant bearing the king's arms emblazoned, and with him another who carried a plume on the point of his lance. On his left rode his son James, unfortunate in afterwards incurring the hatred of his mother, who perhaps prevented him from being elected to the throne of Poland; on his right was his old rival, Charles of Lorraine. Before the battle the king knighted his son and made a patriotic address to his troops, in which he told them that on that occasion they did not defend Vienna alone, but rather all Christendom, and that they were not fighting for an earthly sovereign but for the King of kings. The shouts of the soldiers bore to the enemy the dreaded name of Sobieski, familiar to them on many a well-fought field. He is said to have been provoked to give the order for battle by seeing Kara Mustapha, the Turkish commander, tranquilly taking coffee with his two sons in his splendid tent.

The assault was made simultaneously on the wings and centre of the enemy. The king himself dashed forward to the pasha's tent, bearing down all opposition and repeating with a loud voice, "Non nobis, non nobis, Domine exercituum, sed nomini Tuo da gloriam." "Allah!" said the Mongol khan, "the king is surely among them." In spite of the bravery of the Turks they were overpowered by the *élan* of the Poles. Six pashas were slain, and the vizier fled with the remnant of his army. The booty taken was immense. The details of the battle may be gathered from the interesting letters which Sobieski wrote to his wife in the Polish language. She was a Frenchwoman, daughter of Henri de la Grange, captain of the guard to Philip, duke of Orleans, and had been originally maid of honor to Louisa, queen of Wladystaw IV., was then married to Count Zamoiski, and after his death became the wife of Sobieski. It is said that chiefly on her account the Polish king was induced to assist Austria. The selfish policy of Louis XIV. would have allowed this outpost of Christian Europe to be taken by the Turks, and he used all the secret springs of his diplomacy to divert Sobieski from his purpose. He had, however, given mortal offence to this ambitious woman in refusing the title of duke to her father. After the complete rout of the Moslem, Sobieski and his troops entered Vienna, and divine service was performed in the cathedral; a priest read aloud the text, "There was a man sent from God, whose name was John." In spite of his success, the brave Pole was doomed to meet with ingratitude at the hands of the emperor Leopold, and through the selfishness of his own troops and the Lithuanian contingent, who seem to have been always at cross purposes with the Poles, he was not able to follow up his victory to its legitimate end.

The king, after this brilliant achievement, showed some inclination to be reconciled to Louis XIV., but the emperor succeeded in diverting him by holding out hopes of securing the government of Moldavia and Wallachia for his son. By the treaty of Moscow, which Sobieski concluded in 1686 with Sophia, the regent of Russia, Smolensk, Severia, Tchernigoff, and Kieff were definitely annexed to the latter country. The private life of Sobieski was embittered by family dissensions; he was very much under the influence of his wife, a woman of great beauty, but avaricious, fond of power, and revengeful. Thus the illustrious soldier had not peace in his own house, nor was he likely to meet with it in the stormy debates of the diet, several of which were broken off by the exercise of the *liberum veto*; and so weariness had his position become that he several times thought of abdicating, and the Austrian party (such was the gratitude he met with) sought to effect this. He finally sank under an accumulation of disorders, and expired on the 17th June, 1696, at his favorite castle of Wilanow. Many incidents of his death-bed have been recorded by Żatowski, the bishop of Plock, which show that the king died ill at ease, being filled with the gravest apprehensions concerning the future of his country. The family is now extinct. With him sank the glory of Poland, which was rapidly hastening to its fall.

After a time the diet met as usual to elect the new sovereign. The three chief candidates were James Sobieski, the son of the late king; the prince of Conti, nephew of the great Condé; and the elector of Saxony. The elector was appointed, and in order to qualify for the throne, abjured Protestantism. In 1699, by the peace of Carlowitz, the Turks renounced all claim over the Ukraine and Podolia, but the king was foolish enough to allow himself to be drawn into a war with the Swedes, in consequence of which Cracow was taken in 1702. Charles XII. of Sweden became master of the country, and deposed the newly elected Frederick Augustus, in whose place was chosen Augustus II. Stanislaw Leszczyński, palatine of Posen, (1698-1738). a man of benevolence and learning. All the courts of Europe recognized this new king except the czar Peter, and when the latter defeated Charles at the battle of Poltava in 1709 Leszczyński was compelled to leave the country, and Augustus II., as he was styled, was restored. Stanislaw at the approach of the Russian troops retired to Lorraine which he governed till his death at an advanced age. In this reign Poland lost Courland, which had long been one of its fiefs, but was now seized by the Russians and given by the empress Anne to her favorite Biren. The Dissidents, as the Protestants were called, were slowly decreasing in number, and in an *émeute* which occurred at Thorn in 1724 many were cruelly put to death. A little later, in 1733, a law was passed by which they were declared incapable of holding any office or enjoying any dignity. Augustus II. died at Warsaw in the last-mentioned year. He was a contemptible king, notorious for his private vices. At the instigation of many of the Poles, Stanislaw Leszczyński, who was now residing in Lorraine, and who had become the father-in-law of Louis XV., was induced to return to Poland, and was elected king at Warsaw by a large majority. This election, however, was displeasing to Austria and Russia, who resolved to resist his pretensions and to secure the election of Frederick Augustus, the son of the late king. A Russian army arrived in the neighborhood of Warsaw, and a party of the nobles opposed to the French influence proclaimed the Saxon. He accordingly swore to the *pacta conventa*, and was crowned king at Cracow in 1734. Meanwhile the unfortunate Stanislaw fled to Dantzic, where he hoped to hold out till assistance should arrive from France. The city, however, was obliged to capitulate after a siege of five months; and

Frederick Augustus
(1734-63).

Stanisław, after many adventures and narrow escapes, reached the Prussian dominions. In 1736 a diet of pacification was held at Warsaw, which was followed by a general amnesty. The condition of the country during this reign was deplorable, although Poland was engaged in no wars. Factions rent the government, and the peasantry, crushed and suffering, betook themselves to robbery and pillage. The king was a man of low tastes, and abandoned himself to pleasure. One of his favorite amusements was shooting dogs from the windows of his palace at Warsaw, in consequence of which dogs became very scarce in the city. He was too idle to learn a word of Polish, and left everything to the management of his minister Brühl. Frederick died on October 3, 1763, at Dresden, where he was buried. In 1764 Stanisław August Poniatowski

Stanislaus Augustus (1764-95).

was elected king, chiefly through the machinations of the Russian empress Catherine. The new monarch was a man of refined manners and elegant mind, but weak, and a mere puppet in Muscovite hands. He caused the *liberum veto* to be abolished, but it was soon restored (in 1766), in consequence, it is said, of Russian influence, as the ruin of Poland had been resolved upon. In 1768 a few patriots met at the little town of Bar in Podolia, and formed what was called the Confederation of Bar, their object being to free the country from foreign influence. Among the members of this confederation were the Pulawskis (Casimir and Joseph), Joachim Potocki, and Adam Krasinski, bishop of Kamenets. Their military operations extended over all Poland and Lithuania, but the Russian troops stationed round the capital prevented the junction of the confederates with the national army. Moreover the confederates, whose number amounted to about eight thousand fighting men, were badly organized. In spite of a few trifling successes they saw their efforts gradually growing weaker. Nor did a bold attempt to carry off the king result in success. Their party speedily broke up, and Casimir Pulawski, one of the leading spirits, left the country and joined the Americans in their War of Independence, in which he soon afterwards perished. In consequence of the efforts of these patriots the pernicious *liberum veto* was put a stop to, though afterward for a short time restored; but the partition of the country had already been secretly agreed upon by Russia, Prussia, and Austria. The idea appears to have been first suggested by Frederick the Great. M. Rambaud, in his *Histoire de la Russie*, gives the following as the chief causes which led to the destruction of Poland, which, in addition, had always suffered from the want of natural frontiers:

1. The national movement in Russia, which fostered the idea of recovering the provinces in the west which had formerly been Russian territory, and spoke a language but little differing from Russian. To this was to be added the fact that the majority of the inhabitants were members of the Greek Church. This feeling had already led to the conquest of some of the western provinces in the time of Alexis Mikhailovich as previously mentioned. Moreover, the members of the Greek Church were being constantly persecuted by the Jesuits, who had done so much mischief to the country.

2. The great desire of Prussia to become possessed of the lower part of the Vistula, with the towns of Thorn and Dantzic. A reason for Prussian interference was afforded by the Polish persecution of the "Dissidents," as a sample of which the cruelties committed at Thorn may be cited.

3. The general political condition of Poland—an anachronism among the nations of Europe. They had become strong by centralized power and by harmonizing their governments with the spirit of the age. In Poland there was no middle class; for the trade in the towns was in the hands of foreigners, and especially Jews.

There were to be seen a proud nobility, the members of which were engaged in constant feuds among themselves, and far below them miserable serfs deprived of all political rights. There was no national spirit in the country, no sympathy between the nobility

and peasantry. It was the Jews who chiefly busied themselves with commerce; they distributed the products, selling at the same time to the serfs and their masters, and preventing the two classes of the natives of the country to a great extent from coming into contact with each other. By their efforts the economic functions of every-day life were carried on, and yet they could not be considered a real part of the nation. In the moment of danger they were not at hand to bring together distinct classes and to establish a common bond of interest; the nation, thus consisting of men who did not understand each other, remained perplexed and divided. The peasants, who had at one time communal possession of the land, according to the old Slavonic custom, had long ago lost all their rights. Those Poles who struggled for liberty themselves were not willing to extend it to their unhappy serfs. Kosciuszko desired to see serfdom abolished; but the peasants who followed him only enjoyed their liberty during the war, and his decree of emancipation was so vaguely expressed that it was ineffectual. It is strange to think that the real liberators of the peasant were the Russians, who in the revolt of 1863 gave him a portion of the land which he cultivated.

In 1772 Prussia took the palatinates of Malborg, Pomeria, and Warmia, Culm, except Dantzic and Thorn, and a part of Great Poland; Austria took Red Russia or Galicia, with a part of Podolia, Sandomir, and Cracow; and Russia took White Russia, with all the part beyond the Dnieper. The Poles were obliged to sanction this plundering of their country in a diet held in 1778. The only real benefit conferred on the nation by this diet was the introduction of a better system of education; the Jesuits were also suppressed, and their immense estates became national property. Although the country had been mutilated in this fashion, it yet enjoyed tranquillity for a short time, and even made some material progress. Thus some useful manufactures were introduced. In 1788 a remarkable diet was opened, which lasted four years—the longest on record, for the others had only endured a few days or a few weeks at most. At this many important changes were introduced, such as the amelioration of the condition of the burghers and peasants; but it was now too late. On this occasion the *liberum veto* was decisively suppressed and the throne declared hereditary. The elector of Saxony, grandson of the wretched and incapable Augustus III., was declared the successor of Stanislaus. The Roman Catholic was to be the dominant religion, but the Dissidents were to be tolerated. The burghers were to send deputies to the diet on the same footing as the nobles. The peasants were not yet emancipated, but their condition was improved. The new constitution was finally promulgated on the 3d May, 1791. The king and the two chambers took the oaths to preserve it. The country now seemed to breathe afresh, and to be established upon a new basis. But the selfishness of the Polish nobles, who had always been the evil genius of the country, overturned all the arrangements. Among the most prominent non-contents was Felix Potocki, who was anxious to restore to the nobility the privileges they had lost by the new constitution. In concert with him were Francis Xavier Branicki and Severin Rzewuski, who sought the assistance of foreign powers, and especially Russia. These enemies of their country formed, in 1792, the Confederation of Targowica, and soon afterwards, at their instigation, Russian troops invaded Poland and Lithuania. The feeble king, Stanislaus Augustus, made no resistance; he signed the convention of Targowica, and the Russians occupied Warsaw. In 1793 another treaty of partition was signed, by which Prussia acquired the remainder of Great and a portion of Little Poland, and the Russian boundary was advanced to the centre of Lithuania and Volhynia. An insurrection now broke out under the leadership

Partition of the country.

of Thaddeus Kosciuszko, which at first made head against the Prussians and Russians, who had invaded the country from all quarters; but the successes of the insurgents were stained by the murders committed by the popular party at Warsaw. Suwaroff now entered the country, and Kosciuszko was finally defeated and made prisoner at the battle of Maciejowice in 1794; there is no truth, however, in the assertion that he cried out on that occasion, "Finis Poloniæ;" this he always denied till the day of his death. After storming the suburb Praga, Suwaroff took Warsaw, and the city was sacked with great cruelty. The kingdom of Poland was now at an end, and the third division took place. Austria had Cracow, with the country between the Pilaca, the Vistula, and the Bug; Prussia had the capital, with the territory as far as the Niemen; and the rest went to Russia. Stanislaus resigned the crown at Grodno on April 25, 1795; he was summoned to St. Petersburg, where he is said to have endured many indignities from the emperor Paul, who never allowed him to remain seated in his presence. There he died in 1798.

Many of the Poles now entered foreign services, as, for instance, the legion which followed the fortunes of France; but the fate of these exiled patriots was often a sad one. Many perished on the burning sands of St. Domingo. Many were killed in the famous expedition to Moscow. The Poles looked anxiously to the success of Napoleon. But all that the conqueror did for them was to form the Duchy of Warsaw, consisting of six departments—Posen, Kalisz, Plock, Warsaw, Lomza, and Bydgoszcz—with a population of more than two millions, which he united with Saxony.

A resettlement of Poland took place by the treaty of Vienna (1814). (1) Austria was to have Galicia and the salt-mines of Wieliczka. (2) Posen was to belong to Prussia. This power was also confirmed in what it had gained at the first partition. (3) The city and district of Cracow were to form an independent republic under the guarantee of the three powers. This historical town was annexed by Austria in 1846, in defiance of all international law. (4) The remainder of ancient Poland, comprising the chief parts of the recent grand duchy of Warsaw (embracing a tract bounded by a line drawn from Thorn to near Cracow on the west, to the Bug and Niemen in the east), reverted to Russia, and was to form a constitutional kingdom subject to the czar. This constitution, considering the circumstances, was a very liberal one. Poland was to be governed by responsible ministers, a senate, and a legislative chamber. There were to be a national army under the national flag and a separate budget. Polish was to be the official language; personal liberty and the freedom of the press were also guaranteed. It was obvious from the first that it would be difficult to unite a country with such a liberal constitution to another still governed by a patriarchal despotism. Zajacok was named viceroy, and the grand-duke Constantine, brother of the emperor Alexander, took the command of the army.

The rebellions of the Poles in 1830 and 1863 more properly belong to Russian history; perhaps, however, a few facts connected with them may be appropriately introduced here.

Considering the delicate position of affairs in Russian Poland, things had worked fairly well. The impulse to the Polish revolution was undoubtedly given by the French. It was begun by some students, who hoped to seize the grand-duke Constantine at his residence, Belvedere, in the vicinity of Warsaw. In the evening of November 29, 1830, they accordingly proceeded to the palace, but did not succeed in capturing the grand-duke. The city, however, rose, the troops fraternized with the people, and the chief command was entrusted to General Chlopicki, a veteran of the wars of Napoleon. Early in 1831 a large Russian army, commanded by

Diebitsch, advanced to reduce them to submission. Chlopicki laid down his dictatorship, but the Poles pursued the insurrection with vigor under the command of Prince Adam Czartoryski. They were disappointed in their hopes of assistance from foreign powers. On the 8th September Warsaw surrendered to Paskewitch, who had taken the command, Diebitsch having died of cholera (June 10th), and a few weeks afterwards the grand-duke Constantine died at Vitebsk. On February 26, 1832, Poland was declared a Russian province.

No other outbreak occurred till 1863, but for some time previously the country had been disturbed. On the 29th November, 1860, on the occasion of the thirtieth anniversary of the revolution of 1830, many political manifestations took place both in the churches and streets, and portraits of Kosciuszko and Kilinski, a patriot of the time of the last partition, were distributed. Some riots took place, and unfortunately several persons were killed. These proceedings were followed by concessions from the emperor Alexander, who established municipal institutions in Warsaw and the chief cities of the kingdom. The Russian czar was acting under the advice of Wielopolski, a Pole, who was appointed director of public instruction and worship. Riots, however, still continued, and in 1862 the grand-duke Constantine was named viceroy. On the night of January 15, 1863, a secret conscription was held, and the persons suspected of being most hostile to the Government were dragged from their beds and enlisted as soldiers. Immediately after this the insurrection broke out, which was directed by a secret committee (Rząd), the proceedings of which were as mysterious as those of the Fehmgerichte. Soon after bands of rebels began to make their appearance in the Polish forests. There were, however, no regular battles between the Russian troops and the Poles,—only guerilla fighting, in which the Poles, under the greatest disadvantages, showed splendid heroism. The secret emissaries of the revolutionary Government, armed with daggers, succeeded in putting to death many Russian spies—not the least memorable case being that of the Jew Hermani, stabbed while on the staircase of the Hôtel de l'Europe at Warsaw. On the other hand the chiefs of the insurgents captured were shot or hanged. Langiewicz held out for some time, but was defeated by the Russians, and succeeded in making his escape into Galicia. A reign of terror was inaugurated by General Mouravieff, and all attempts at reconciliation made by the great powers of Europe were useless. By May, 1864, the rebellion was quite suppressed, and it will be seen by the results that it cost Poland dear. The kingdom of Poland now ceased to exist; it has been parcelled out into six governments. The Russian language was ordered to be used in all public documents instead of Polish, and the university of Warsaw has been Russified, all lectures now being delivered in that language.

We have not dwelt upon the terrible massacres of the Polish nobles by the peasants in Galicia in 1846, said to have been instigated by the Austrian Government. This province has been tolerably quiet since, but the Poles have to struggle with the large Ruthenian or Red-Russian population, speaking a different language, and adherents of the Greek Church or Uniates.

In Prussian Poland, though it is but fair to add that we hear no stories of massacres, the Germanization of the province has been more complete. Posen will soon be lost as a Polish town, and many historical places have had their names obliterated for such substitutes as Bismarcksdorf and Sedan.

POLISH LITERATURE.

The Polish Language, according to the latest statistics, is still spoken by nearly ten millions of people,

Resettlement by treaty of Vienna.

Rebellion of 1863.

Rebellion of 1830.

distributed, according to the *Revue Slave* (Warsaw, 1878, vol. i. p. 78), as follows: in Russia, 4,640,000; in Austria, 2,444,200; in Prussia, 2,405,800; in Turkey, 10,000. It belongs to the western branch of the Slavonic tongues, and exhibits the closest affinities with the Czech or Bohemian and Lusatian Wendish (see SLAVONIC LANGUAGES). Unlike the people of other Slavonic countries, the Poles are comparatively poor in popular and legendary poetry, but such compositions undoubtedly existed in early times, as may be seen by the writings of their chroniclers; thus Gallus translated into Latin a poem written on Bolesław the Brave, and a few old Polish songs are included in Wojciełki's *Library of Ancient Writers*. A great deal of the early literature written in Poland is in Latin. The earliest specimen of the Polish language is the so-called Psalter of Queen Margaret, discovered in 1826 at the convent of St. Florian. The date of the MS. appears to be the middle of the 14th century, and probably in its present form it is only a copy of a much older text; there is also a translation of the fiftieth psalm belonging to the 13th century.* The ancient Polish hymn or war song, "Pieśń Boga Rodzica," was an address to the Virgin, sung by the Poles when about to fight. The oldest manuscript of this production is dated 1408, and is preserved at Cracow. By a legend which subsequently grew up the composition of it was assigned to St. Adalbert. John Łódzia, bishop of Posen from 1335 to 1346, composed several religious songs in Latin.

The next monument of Polish literature to which we come is the Bible of Queen Sophia or Bible of Szarospatak. It is imperfect, and only contains the early books, viz., the Pentateuch, Joshua, Ruth, and Kings; there are, however, fragments of three others. It is said to have been written for Sophia, the fourth wife of Jagiełło, about the year 1455. It has been edited with great care by Matecki. Five religious songs in Polish dating from the 15th century have been preserved; they are ascribed to Andrew Słopuchowski, prior of the monastery of the Holy Cross on Łysa Góra. There is also the fragment of a hymn in praise of Wickliffe. To these fragments may be added the prayer book of a certain Wactaw, a sermon on marriage, and some Polish glosses. These are all the existing memorials of the Polish language before the 16th century.

Perhaps a few words should be said concerning the writers in Latin. Martin Gallus lived in Poland between 1110 and 1135. From his name he has been supposed by some to have been a Frenchman, and we must remember that Poland swarmed at that time with foreign ecclesiastics. Lelewel, the Polish historian, considers that it is merely a translation into Latin of some such name as *Kura*, signifying "a fowl." Others suppose him to have been an Italian, or a monk from the convent of St. Gall in Switzerland. He has plenty of legends to tell us, and writes altogether in a poetical style, so that his prose seems to fall into rhythm unconsciously. His quotations from the classics, Sallust, Lucan, and others, show the extent of his reading. Gallus was followed by Matthew Cholewa and Vincent Kadłubek, two bishops of Cracow, and Bogufal or Boguchwał (Gottlob), bishop of Posen, who all used Latin. The work of Kadłubek is more ornate in diction than that of Bogufal and for a long time enjoyed great popularity. He was born in 1160, educated at the university of Paris, and died in Poland in 1223, as a Cistercian monk. His Latin, like that of Gallus, is far from classical, but he writes with spirit and throws a good deal of light upon the events of his time. The education of the country was wholly in the hands of the ecclesiastics, many of whom were foreigners. In this way we must explain the great prevalence of the Latin lan-

guage. Such a system would be sure to stifle all national outgrowth, and accordingly we have among the Poles none of those early monuments of the language which other countries boast. For instance, there are no *lilint* or legendary poems, such as are found among the Russians, although many passages in the ancient chroniclers from their poetical coloring seem to be borrowed from old songs or legends, and the first verses of some of these compositions have been preserved. Mention may here be made of other chroniclers such as Martin the Pole (Polonus) who died in 1279 or 1280, and Jan of Czarńkow, who died in 1389; the latter was the historian and panegyrist of Kazimierz the Great. With the reign of Kazimierz III. (1333 to 1370) must be associated the statutes of Wislica. Jadwiga, the wife of Jagiełło, was mainly instrumental in creating the university of Cracow, which was not founded, however, till 1400. In this institution for many years all the great men of Poland were trained—among others Gregory of Sanok, Długosz, and Copernicus. Kazimierz the Great may be said to have laid the foundation of this university. Having obtained the consent of Pope Urban V., he established at Cracow a *studium generale* on the model of the university of Bologna. It consisted of three faculties—Roman law, medicine, and philosophy. But the aristocratic youth still preferred frequenting the universities of Prague, Padua, and Paris, and accordingly the newly-founded *studium* languished. Jadwiga, however, obtained from Boniface IX. permission to create a new chair, that of theology; and the university of Cracow was remodelled, having been reorganized on the same basis as that of Paris. Another university was founded later at Vilna by Batory, and one at Zamość by the chancellor Zamoiski. There were also good schools in various places, such as the Collegium Lubrańskiego of Posen and the school of St. Mary at Cracow. In the year 1474 a press was set up in the latter city, where Günther Zainer printed the first book. The first press from which books in the Polish language appeared was that of Hieronymus Wietor, a Silesian, who commenced publishing in 1515. A few fragments printed in Polish had appeared before this, as the Lord's Prayer in the statutes of the bishops of Breslau in 1475, the story of Pope Urban in Latin, German, and Polish in 1505, etc.; but the first complete work in the Polish language appeared from the press of this printer at Cracow in 1521, under the title *Speeches of the Wise King Solomon*. The translation was executed by Jan Koszycki, as the printer informs us in the preface, and the work is dedicated to Anna Wojnicka, the wife of a castellan. In 1522, a Polish translation of Ecclesiastes appeared from that press, and before the conclusion of that year *The Life of Christ*, with woodcuts, translated into Polish by Balthasar Opec. Many other presses were soon established. Printers of repute at Cracow, during the 16th and beginning of the 17th century, were Sybeneicher and Piotrkowczyk.

Little as yet had been produced in Polish, as the chroniclers still adhered to Latin; and here mention must be made of Jan Długosz, who called himself Longinus. He was bishop of Lemberg, the capital of Galicia, and has left us a very valuable history which has merits of style and shows considerable research. So anxious was Długosz to make his work as perfect as he could that he learned Russian so as to be able to read the *Chronicle* of Nestor. The best part of his book is that which treats of the period between 1386 and 1480. About 1500 was written an interesting little work entitled "Memoirs of a Polish Janissary" (*Pamiętniki Janeczara Polaka*). Although written in the Polish language, it was probably the production of a Serb, Michael Konstantinovich of Ostrovitz. He was taken prisoner by the Turks in 1455 and served ten years among the Janissaries, after which he escaped into Hungary. About this time also flourished

* The Psalter is called after Margaret, the first wife of King Louis, who died in 1349, by a mere conjecture. Caro thinks it more probable that the book belonged to Mary, his daughter.

Nicholas Copernicus, a native of Thorn, one of the few Poles who have made themselves known beyond the limits of their country.

The Poles call the period between 1548 and 1606 their golden age. Poland was the great land of Eastern Europe, and owing to the universal toleration encouraged by the government Protestantism was widely spread. Many of the chief nobility were Calvinists, and the Socini came to reside in the country. All this, however, was to pass away under the great Jesuit reaction. At Rakow in Poland was published the catechism of the Socinian doctrines in 1605. The Jesuits made their appearance in Poland in 1564, and soon succeeded in getting the schools of the country into their hands. Besides extirpating the various sects of Protestants, they also busied themselves with destroying the Greek Church in Lithuania. Latin poetry was cultivated with great success by Clement Janicki (1516-1543) but the earliest poet of repute who wrote in Polish is Rej of Nagłowice (1505-69). After a somewhat idle youth he betook himself to poetry. He was a Protestant, and among other religious works translated the Psalms. His best work was *Zwierciadło albo zwierciadło Poczciwego Człowieka* ("The Mirror or Life of an Honorable Man"),—a somewhat tedious didactic piece. He was also the author of a kind of play—a mystery we may term it, and productions of this sort seem to have been common in Poland from a very early time—entitled *Life of Joseph in Egypt*. This piece is interesting merely from an antiquarian point of view; there is but little poetry in it. It teems with anachronisms; thus we have mention of the mass and organs, and also of a German servant.

Jan Kochanowski (1530-1584), called the prince of Polish poets, came of a poetical family, having a brother, a cousin, and a nephew who all enriched the literature of their

country with some productions. Kochanowski studied for some time at the university of Padua, and also resided in Paris, where he made the acquaintance of Ronsard, then one of the most celebrated poets. He exercised his talents in various ways; thus he has left *The Game of Chess*, an imitation of Vida, and *Proporzec albo Hold Pruski* ("The Standard or Investiture of Prussia"), where he describes the feat done by Albert of Brandenburg to Sigismund Augustus. He also wrote the first regular play, and executed a translation of the Psalms. The title of his play—a piece of one act, with twelve scenes—is *The Despatch of the Greek Ambassadors*. It is written in rhymeless five-foot iambics, and is altogether a product of the Renaissance, reminding us of some of the productions of George Buchanan. Rhyme is employed in the choruses only. It was acted on the marriage of the chancellor Jan Zamoiski with Christine Radziwiłł, in the presence of King Stephen and his wife, at Ujazdowo near Warsaw, in 1578. The poet's most popular work, however, is his *Treny* or "Lamentations," written on the death of his daughter Ursula. These beautiful elegies have been justly praised by Mickiewicz; they are enough to raise Kochanowski far above the level of a merely artificial poet. Besides poems in Polish he also wrote some in Latin. It will be observed that we get this double-sided authorship in many Polish writers. They composed for an exclusive and learned circle, certainly not for the Jew, the German trader of the town, or the utterly illiterate peasant. It may be said with truth of Kochanowski that, although the form of his poetry is classical and imitated from classical writers, the matter is Polish, and there is much national feeling in what he has left us. Mention must also be made of his epigrams, which he styled "Trifles" (*Fraszki*); they are full of spirit and geniality. Stanislaus Grochowski (1554-1612) was a priest; but his poetry is of little merit, although he was celebrated in his time as a writer of panegyrics. His satire *Babie Kolo* ("The Women's Circle") gave offence on account of its personalities. A great partisan of the Catho-

lies in the time of Sigismund III. was Caspar Miaskowski, whose *Waleta Wioszczonowska* ("Farewell to his Native Country") deserves mention. Szarzyński, who died young in 1581, deserves notice as having introduced the sonnet to the Poles. This species of poetry was afterward to be carried to great perfection by Mickiewicz and Gaszynski.

Szymonowicz (1554-1624) was a writer of good pastorals. Although they are imitated from classical writers, he has introduced many scenes of national life, which he describes with much vigor. Among the best are "The Lovers," "The Reapers," and "The Cake" (*Kotacz*). Mickiewicz is very loud in his praise, and considers him one of the best followers of Theocritus. The condition, however, of the Polish peasants was too miserable to admit of their being easily made subjects for bucolic poetry. There is an artificial air about the idyls of Szymonowicz which makes one feel too keenly that they are productions of the Renaissance; one of their best features is the humane spirit towards the miserable peasantry which they everywhere display. Another excellent writer of pastorals was Zimorowicz, a native of Lemberg, who died at the early age of twenty-five. Some of his short lyrics are very elegant, and remind us of Herrick and Carew,—e.g., that beginning "Ukochana Lancelloto! Ciebie nie proszę o złoto." Another writer of pastorals, but not of equal merit, was Jan Gawinski, a native of Cracow. Some good Latin poetry was written by Casimir Sarbiewski, better known in the west of Europe as Sarbievius (d. 1640). He was considered to have approached Horace more nearly than any other modern poet, and a gold medal was given him by Pope Urban VIII. Martin Kromer (1512-1589) wrote a history of Poland in thirty books, and another volume, giving a description of the country and its institutions,—both in Latin. The history is written in an easy style and is a work of great merit. A poet of some importance was Klonowicz (1545-1602), who Latinized his name into Acernus, *Klon* being the Polish for maple, and wrote in both Latin and Polish. Sometimes he is descriptive, as in his Polish poem entitled *Fłis* ("The Boatman"), in which he gives a detailed account of the scenery on the banks of the Vistula. There is some poetry in this composition, but it alternates with very prosaic details. In another piece, *Rhocolania*, in Latin, he describes the beauties of Galicia. Occasionally he is didactic, as in *Worek Judaszow* ("The Bag of Judas") and *Victoria Deorum*, where, under the allegory of the gods of Olympus, he represents the struggles of parties in Poland, not without severely satirizing the nobility and ecclesiastics. A curious work called *Quincunx*, written by Orzechowski, is concerned with religious polemics. Andrew Modrzewski, a Protestant, in his work *De Republica Emendanda* (1551), recommended the establishment of a national church which should be independent of Rome, something upon the model of the Anglican.

A florid Jesuitical style of oratory became very popular in the time of Sigismund III., not without rhetorical power, but frequently becoming tawdry. The chief representative of this school was Peter Skarga, one of the main agents in extirpating Calvinism in Poland and the Greek Church in Lithuania. Among his numerous writings may be mentioned *Lives of the Saints*, *Discourses on the Seven Sacraments*, and especially his sermons preached before the diet, in which he lashed the Poles for their want of patriotism and prophesied the downfall of the country. Mecherzynski, in his "History of Eloquence in Poland" (*Historia Wymowy w Polsce*), especially praises his two funeral sermons on the burial of Anna Jagiełłonka, widow of Stephen Batory, and Anna of Austria, first wife of Sigismund III. Besides the Latin histories of Wapowski and Gwagnin (Guagnini, of Italian origin), we have the first historical work in Polish by Martin Bielski, a Protestant, viz., *Kronika*

Polska, which was afterwards continued by his son. The author was born in 1495 on his father's estate, Biata, and was educated, like so many other of his illustrious contemporaries, at the university of Cracow. He lived to the age of eighty; but, however great were the merits of his *Chronicle*, it was long considered a suspicious book on account of the leanings of the author to Calvinism. After his death his work was continued by his son Joachim (1540-1599). There is also a *Chronicle* by Bartholomew Paprocki. In 1582 was also published the *Chronicle* of Strykowski, full of curious learning, and still of great use to the student of history. Five years later appeared the *Annales Poloniae* of Sarnecki. The last three works are in Latin.

A few words may be said here about the spread of Protestantism in Poland, which is so intimately mixed up with the development of the national language. The doctrines of Huss had entered the country in very early times, and we find Polish recensions of Bohemian hymns; even the hymn to the Virgin previously mentioned is supposed to have a Czech basis. The bishops were soon active against those who refused to conform to the doctrines of the Roman Church. Thus we find that Bishop Andrew of Brnin seized five Hussite priests and caused them to be burnt in the market of Posen in 1439. A hundred years afterwards a certain Katharina Malcher, on account of her Utraquist opinions, was condemned by Gamrat, the bishop of Cracow, to be burnt, which sentence was accordingly carried out in the ragmarket at Cracow. As early as 1530 Lutheran hymns were sung in the Polish language at Thorn. In Königsberg John Seklucyan, a personal friend of Luther, published a collection of *Christian Songs*. He was born in Great Poland, and was at first a Roman Catholic priest in Posen, but afterwards embraced the Protestant faith and was invited by Duke Albert as a preacher to Königsberg, where he died in 1578. He executed the first translation of the New Testament in 1551. Four years afterwards appeared a complete Polish Bible published by Scharffenberg at Cracow. In 1553 appeared at Brześć the Protestant translation of the whole Bible made by a committee of learned men and divines, and published at the expense of Nicholas Radziwiłł, a very rich Polish magnate who had embraced the Protestant doctrines. This book is now of great rarity because his son Christopher, having been induced to become a Roman Catholic by the Jesuit Skarga, caused all copies of his father's Bible which he could find to be burnt. One, however, is to be seen in the Bodleian Library, and another in the library of Christ Church, at Oxford. A Socinian Bible was issued by Simon Budny in 1570 at Nieśwież, as he professed to find many faults in the version issued under the patronage of Radziwiłł; in 1597 appeared the Roman Catholic version of the Jesuit Wujek; and in 1632 the so-called Dantzie Bible, which is in use among Protestants and is still the most frequently reprinted.

Up to this time Polish literature, although frequently rhetorical and too much tinged with classical influences, had still exhibited signs of genius. But now, owing to the frivolous studies introduced by the Jesuits, the so-called macaronic period supervened, which lasted from 1606 to 1764, and was a time of great degradation for the language and literature. The former was now mixed with Latin and classical expressions; much of the literature consists of fulsome panegyric, verses written on the marriages and funerals of nobles, with conceits and fantastic ideas, devoid of all taste, drawn from their coats of arms. The poets of this period are, as may be imagined, in most cases mere rhymsters; there are, however, a few whose names are worth recapitulating, such as Wacław Potocki (c. 1622-c. 1696), now known to have been the author of the *Wojna Chocimska*, or "War of Khotin," the same campaign which afterwards formed the

subject of the epic of Krasicki. At first the author was supposed to have been Andrew Lipski, but the real poet was traced by the historian Szajnoch. The epic, which remained in manuscript till 1850, is a genuine representation of Polish life; no picture so faithful appeared till the *Pan Tadeusz* of Mickiewicz. Moreover Potocki had the good taste to avoid the macaronic style so much in vogue; his language is pure and vigorous. He does not hesitate to introduce occasionally satirical remarks on the luxury of the times, which he compares, to its disadvantage, with the simplicity of the old Polish life. There is also another poem attributed to Potocki called the *New Mercury*. In one passage he censures King Michael for ceding Podolia to the Turks. Samuel Twardowski (1600-1660) was the most prolific poet of the period of the Vasas. His most important poem is *Władysław IV., King of Poland*, in which he sings in a very bombastic strain the various expeditions of the Polish monarch. A bitter satirist appeared in the person of Christopher Opalinski (1609-1656). His works were published under the title of *Juvenalis Redivivus*, and, although boasting but little poetical merit, give us very curious pictures of the times. Vespasian Kochowski (born between 1630 and 1633, died in 1699) was a soldier-poet, who went through the campaigns against the Swedes and Cossacks; he has left several books of lyrics full of vivacity. Another poet was Andrew Morsztyn (born about 1620, died about the commencement of the 18th century), an astute courtier, who was finance minister (*podskarbi*) under John Casimir, and was a devoted adherent of the French party at court, in consequence of which, in the reign of Sobieski, he was compelled to leave his native country and settle in France (see p. 290). His poems are elegant and free from the conceits and pedantry of the earlier writers. In fact, he introduced into Poland the easy French manner of such writers as Voiture. He translated the *Cid* of Corneille, and wrote a poem on the subject of *Psyche*, based upon the well-known Greek myth. History in the macaronic period made a backward step: it had been written in the Polish language in the golden age; it was now again to take a Latin form, as in the *Chronica Gestarum in Europa Singularium* of the ecclesiastic Paul Piasecki (1580-1649), who is an authority for the reigns of Sigismund III. and Władysław IV., and Rudawski, who describes events from the accession of John Casimir to the peace of Oliwa (1648-1660); and as valuable materials for history may be mentioned the five huge volumes of Andrew Chrysostom Żaruski (1711), bishop of Warmia. This work is entitled *Epistolæ Historico-Familiares*. It would be impossible to recapitulate here the great quantity of material in the shape of memoirs which has come down, but mention must be made of those of John Chrysostom Pasek, a nobleman of Masovia, who has left us very graphic accounts of life and society in Poland; after a variety of adventures and many a well-fought battle, he returned to the neighborhood of Cracow, where he died between 1699 and 1701. Some of the most characteristic stories illustrating Polish history are drawn from this book. A later period, that of the miserable epoch of Augustus III., is described very graphically in the memoirs of Matuszewicz, first edited by Pawinski at Warsaw in 1876. Relating to the same period are also the memoirs of Bartholomew Michalowski (*Pamiętniki Bartłomieja Michalowskiego*). A curious insight into the course of education which a young Polish nobleman underwent is furnished by the instructions which James Sobieski, the father of the celebrated John, gave to Orchowski the tutor of his sons. This has been twice printed in comparatively recent times (*Instrukcyja Jakóba Sobieskiego kasztelana Krakowskiego dana panu Orchowskiemu ze strony synów*, Vilna, 1840). The old gentleman in his aristocratic imperiousness frequently reminds us of the amusing directions given by Sir John Wynne to his chaplain, quoted in Pennant's *Tour in Wales*.

A *History of the Lithuanians* in Latin was published by the Jesuit Koiałowicz; the first volume appeared at Dantzig in 1650. A valuable work on the condition of Poland was written by Stanisław Leszczyński, who was twice chosen king, entitled *Głos wolny wolność ubezpieczający* ("A Free Voice Guaranteeing Freedom"), where he tells the Poles some homely and perhaps disagreeable truths illustrating the maxim *Summa libertas etiam perire volentibus*.

A notable man was Joseph Andrew Załuski, bishop of Kieff, a Pole who had become thoroughly Frenchified—so much so that he preached in French to the fashionable congregations of Warsaw. He collected a splendid library of about 300,000 volumes and 15,000 manuscripts, which he bequeathed to the Polish nation; but it was afterwards carried off to St. Petersburg, where it formed the foundation of the imperial public library. According to Nitschmann in his *Geschichte der Polnischen Litteratur*—a work which has been of service in the preparation of this article—the books were transported to Russia very carelessly, and many of them injured by the way. It was especially rich in works relating to Polish history. Konarski edited in six volumes a valuable work entitled *Volumina Legum*, containing a complete collection of Polish laws from the time of the statute of Wislica. He did much good also in founding throughout the country schools for the education of the sons of the upper classes, but as yet nothing had been done for popular education properly so-called. About the close of this period we have some valuable writers on Polish history, which now began to be studied critically, such as Hartknoch in his *Alt- und Neues Preussen* (1684), a work in which are preserved interesting specimens of the old Prussian language, and Lengnich (1689–1774), author of the valuable *Jus Publicum Regni Poloniae*, which appeared in 1742.

We now come to the reign of the last Polish king, Stanisław Poniatowski, and the few quiet years before the final division of the country, during which the French taste was all-powerful. This is the second great period of the development of Polish literature, which has known nothing of mediæval romanticism. The literature of the first or Renaissance period gives us some good poets, who although occasionally imitators are not without national feeling, and a goodly array of chroniclers, most of whom made use of Latin. In the second or French period we get verse-makers rather than poets, who long to be Frenchmen, and sigh over the barbarism of their country; but the study of history in a critical spirit is beginning under the influence of Naruszewicz, Albertrandi, and others. In the third period, that of modern romanticism, we get true nationalism, but it is too often the literature of exile and despair. Here may be mentioned, although living a little time before the reign of Stanisław, a Polish poetess, Elizabeth Drużbacka (1695–1760), whose writings show a feeling for nature at a time when verse-making of the most artificial type was prevalent throughout the country. The portrait prefixed to the Leipzig edition of her works is a striking one, representing a handsome, intellectual-looking woman, dressed in the garb of some religious order. Her *Life of David* in verse appears tedious, but many of the descriptions in the *Seasons* are elegant. Unfortunately she introduces Latinisms, so that her Polish is by no means pure. A national theatre was founded at Warsaw in 1765 under the influence of the court, but it was not till long afterwards that anything really national connected with the drama appeared in Poland. Thomas Kajetan Węgierski, who was chamberlain to the king, enjoyed a considerable reputation among his countrymen for his satirical writing. He was a kind of Polish Churchill, and like his English parallel died young (1755–1787). His life also appears to have been as irregular as Churchill's. In consequence of an attack on the empress of Russia, he was compelled to leave Poland,

and accordingly made a tour in Italy, France, America, and England, dying at Marseilles at the early age of thirty-three. His poetry shows the influence of the French taste, then prevalent throughout Europe. In times of great national disasters he deserves to be remembered as a true patriot; but the spirit of his poetry is altogether unwholesome. It is the wailing cry of a moribund nation. The great laureate of the court of Stanisław was Trembecki (1722–1812), whose sympathies were too much with the Russian invaders of his country. He was little more than a fluent poetaster, and is now almost forgotten. One of his most celebrated pieces was *Zoffjowka*, written on the country seat of Felix Potocki, a Polish magnate, for this was the age of descriptive as well as didactic poetry. Perhaps the English gave the hint in such productions as "Cooper's Hill." The old age of Trembecki appears to have been ignoble and neglected; he had, indeed, "fallen upon evil days and evil tongues"; and when he died at an advanced age all the gay courtiers of whom he had been the parasite were either dead or had submitted to the Muscovite yoke. He comes before us as a belated epicurean, whose airy trifles cannot be warbled in an atmosphere surcharged with tempests and gunpowder. The end of the 18th century was not the period for a court poet in Poland.

The most conspicuous poet, however, of the time was Ignatius Krasicki, bishop of Warmia (1735–1801). He was the friend of Frederick the Great and a prominent member of the king's literary club at Sans Souci. Krasicki wrote an epic on the war of Khotin,—the same as had furnished the subject of the poem of Potocki, of which Krasicki in all probability had never heard, and also that of the Dalmatian Gundulić. Krasicki's poem is at best but a dull affair, in fact a pale copy of a poor original, the *Henriade* of Voltaire. His mock heroics are, to say the least, amusing, and among these may be mentioned *Myszei*, where he describes how King Popiel, according to the legend, was eaten up by rats. His *Monachomachia* is in six cantos, and is a satire upon the monks. The bishop was also the writer of some pretty good comedies. In fact most styles of composition were attempted by him,—of course satires and fables among the number. He presents himself to us much more like a transplanted French abbé than a Pole. In the year 1801 he travelled to Berlin, and died there after a short illness. Among his other works the bishop published in 1781–82 in two volumes a kind of encyclopædia of *belles lettres* entitled *Zbiór Wiadomości*. His estimates of various great poets are not very accurate. Of course he finds Shakespeare a very "incorrect" author, although he is willing to allow him considerable praise for his vigor. Another bishop-poet was Adam Naruszewicz. The existence of so many ecclesiastical writers was a natural feature in Polish literature; they formed the only really cultured class in the community, which consisted besides of a haughty ignorant nobility living among their serfs, and (at a vast distance) those serfs themselves, in a brutalized condition. Burghers there were, properly speaking, none, for most of the citizens in the large towns were foreigners governed by the *Jus Magdeburgicum*. Naruszewicz has not the happy vivacity of Krasicki; he attempts all kinds of poetry, especially satire and fable. He is at best but a mediocre poet; but he has succeeded better as a historian, and especially to be praised is his "History of the Polish Nation" (*Historja Narodu Polskiego*), which, however, he was not able to carry further than the year 1836. He also wrote an account of the Polish general Chodowiecz and translated Tacitus and Horace. Interesting memoirs have been published by Kilinski, a Warsaw shoemaker, and Kosmian, state referendary, who lived about this time and saw much of the War of Independence and other political affairs. Among the

smaller poets of this period may be mentioned Karpiński (1741-1828), a writer of sentimental elegies in the style then so very much in fashion, and Książnin, who nourished his muse on classical themes and wrote some odes; but his poetry is not of a high order. He was the court poet of Prince Adam Czartoryski at Pulawy, and furnished odes in commemoration of all the important events which occurred in the household. He lost his reason on the downfall of Poland, and died after eleven years' insanity in 1807. Julian Ursyn Niemcewicz (1757-1841) was one of the most popular of Polish poets at the commencement of the present century (see NIEMCEWICZ). His most popular work is the "Collection of Historical Songs" (*Spiewy Historyczne*), where he treats of the chief heroes of Polish history. Besides these he wrote one or two good plays, and a novel in letters, on the story of two Jewish lovers. John Paul Woronicz (1757-1829) born in Volhynia, and at the close of his life bishop of Warsaw and primate of Poland, was a very eloquent divine, and has been called the modern Skarga. A valuable worker in the field of Slavonic philology was Linde, the author of an excellent Polish dictionary in six volumes. For a long time the cultivation of Polish philology was in a low state, owing to the prevalence of Latin in the 17th century and French in the 18th. No Polish grammar worthy of the name appeared till that of Kopczynski at the close of the 18th century, but the reproach has been taken away in modern times by the excellent works of Matecki and Malinowski. Rakowiecki, who edited the *Rousskaia Pravda*, and Maciejowski (who died in 1883, aged ninety), author of a valuable work on Slavonic law, may here be mentioned. Here we have a complete survey of all the leading codes of Slavonic jurisprudence. At a later period (in 1856) appeared the work of Helcel, *Starodawne prawa polskięgo pomyki* ("Ancient Memorials of Polish Law"). Aloysius Feliński (1771-1820) produced an historical tragedy, *Barbara Radziwiłł*, and some good comedies were written by Count Alexander Fredro (1793-1876). In fact Fredro may be

Polish
drama.

considered the most entertaining writer for the stage which Poland has produced. He introduced genuine comedy among his countrymen. The influence of Molière can be very clearly seen in his pieces; his youth was spent chiefly in France, where he formed one of the soldiers of the Polish legion of Napoleon and joined in the expedition to Russia. His first production was *Pan Geldhab*, written in 1819 and produced at Warsaw in 1821. From 1819 to 1835 he wrote about seventeen pieces and then abandoned publishing, having taken offence at some severe criticisms. At his death he left several comedies, which were issued in a posthumous edition. There is a good deal of local coloring in the pieces of Fredro; although the style is French, the characters are taken from Polish life. From him may be said to date the formation of anything like a national Polish theatre, so that his name marks an epoch. The Poles like many of the other nations of Europe, had religious plays at an early period. They were originally performed in churches; but, Pope Innocent III. finding fault with this arrangement, the acting was transferred to churchyards. Mention has already been made of plays written by Rej and Kochanowski; they are mere fruits of the Renaissance, and cannot in any way be considered national. The wife of John Casimir, a Frenchwoman, Marie Louise, hired a troop of French actors and first familiarized the Poles with something which resembled the modern stage. The Princess Franciszka Radziwiłł composed plays which were acted at her private residence, but they are spoken of as inartistic and long and tedious. The national theatre was really founded in the reign of Stanislaus Augustus; and good plays were produced by Bohomolec, Kamiński, Kropiński, Boguslawski, Zabłocki, and others. Perhaps, however, with the exception of

the works of Fredro, the Poles have not produced anything of much merit in this line. A great statesman and writer of the later days of Polish nationality was Kołtataj, born at Sandomir in 1750. He was a man of liberal sentiments, and, had his plans been carried out, Poland might have been saved. He wished to abolish serfdom and throw open state employments to all. The nobility, however, were too infatuated to be willing to adopt these wise measures. Like the French aristocrats with the reforms of Necker, they would not listen till ruin had overtaken them. During the last war of Poland as an independent country Kołtataj betook himself to the camp of Kosciuszko, but when he saw that there was no longer hope he went to Galicia, but was captured by the Austrians and imprisoned at Olmütz till 1803. He died in 1812. An active coöperator with Kołtataj was Salesius Jezerski, who founded clubs for the discussion of political questions, and Stanislaus Staszic, who did much for education and improved the condition of the university of Warsaw.

The reputation of all preceding poets in Poland was now destined to be thrown into the shade by the appearance of Mickiewicz Romanticism. (1798-1855), the great introducer of romanticism into the country (see MICKIEWICZ). Poland, as has been said before, is not rich in national songs and legendary poetry, in which respect it cannot compare with its sister Slavonic countries Russia and Servia. Collections have appeared, however, by Wacław Zaleski, who writes under the pseudonyms of Wacław z Oleska, Wojciecki, Roger, Zegota Pauli, and especially Oskar Kolberg. Poland and Lithuania, however, abounded with superstitions and legends which only waited the coming poet to put them into verse. In the year 1851 Romuald Zieliński published *Songs of the People of Pólsk*, and collections have even appeared of those of the Kashubes, a remnant of the Poles living near Dantzic. Mickiewicz had had a predecessor, but of far less talent, Casimir Brodzinski (1791-1835). He served under Napoleon in the Polish legion, and has left a small collection of poems, the most important being the idyl *Wiesław*, in which the manners of the peasants of the district of Cracow are faithfully portrayed. The second great poet of the romantic school who appeared in Poland after Mickiewicz was Julius Stowacki (1809-1849), born at Krzemieniec. In 1831 he left his native country and chose Paris as his residence, where he died. His writings are full of the fire of youth, and show great beauty and elegance of expression. We can trace in them the influence of Byron and Victor Hugo. He is justly considered one of the greatest of the modern poets of Poland. His most celebrated pieces are *Hugo*; *Mnich* ("The Monk"); *Lambro* a Greek corsair, quite in the style of Byron; *Anielli*, a very Dantesque poem expressing under the form of an allegory the sufferings of Poland; *Król Duch* ("The Spirit King"), another mysterious and allegorical poem; *Wacław*, on the same subject as the *Marya* of Malczewski, to be afterwards noticed; *Beniuś*, a long poem in *ottava rima* on this strange adventurer, something in the style of Byron's humorous poems; *Kordyan*, of the same school as the English poet's *Manfred*; *Lilla Weneda*, a poem dealing with the early period of Slavonic history. The life of Stowacki has been published by Professor Anton Matecki in two volumes.

Mickiewicz and Stowacki were both more or less mystics, but even more we may assign this characteristic to Sigismund Krasiński, who was born in 1812 at Paris, and died there in 1859. It would be impossible to analyze here his extraordinary poem *Nieboska Komedia* ("The Undivine Comedy"), *Irydion* and others. In them Poland, veiled under different allegories, is always the central figure. They are powerful poems written with great vigor of language, but enveloped in clouds of mysticism. The life of Krasiński was embittered by the fact that he was the son of

General Vincent Krasinski who had become unpopular among the Poles by his adherence to the Russian Government; the son wrote anonymously in consequence, and was therefore called "The Unknown Poet." Among his latest productions are his "Psalms of the Future" (*Psalm Przyszłości*), which were attacked by the democratic party as a defence of aristocratic views which had already ruined Poland. His friend Słowacki answered them in some taunting verses, and this led to a quarrel between the poets. One of the most striking pieces of Krasinski has the title "Resurrecturis." The sorrows of his country and his own physical sufferings have communicated a melancholy tone to the writings of Krasinski, which read like a dirge, or as if the poet stood always by an open grave—and the grave is that of Poland. He must be considered as, next to Mickiewicz, the greatest poet of the country. Other poets of the romantic school of considerable merit were Gorecki, Wicke, Odyniec, and Gaszynski; the last-named wrote many exquisite sonnets, which ought alone to embalm his name. Witwicki (1800–1847) was a son of a professor at Krzemieniec. He was a writer of ballads and poems dealing with rural life, which enjoyed great popularity among his countrymen and had the good fortune to be set to music by Chopin. The historical works of Lelewel have already had separate mention (see LELEWEL); but here may be specified the labors of Narbutt, *Dzieje Starożytnie Narodu Litewskiego* ("Early History of the Lithuanian People"), published at Vilna in nine volumes, and the valuable *Monumenta Polonice Historica*, edited at Lemberg by Bielowski, of which four volumes have appeared containing reprints of most of the early chroniclers. Bielowski died in 1876.

A further development of romanticism was the so-called Ukraine school of poets, such as Malczewski, Goszczynski, and Zaleski. Anton Malczewski (1793–1826), who died at the early age of thirty-three, wrote one poem, *Marya*, which passed unnoticed at the time of its publication, but after its author's death became very popular. Malczewski led a wandering life and became intimate with Byron at Venice; he is said to have suggested to the latter the story of Mazeppa. *Marya* is a narrative in verse, written with much feeling and elegance, and in a most harmonious metre. The chief poem of Goszczynski is *Zamek Kaniowski* ("The Tower of Kaniow"). The most interesting poem of Bogdan Zaleski is his "Spirit of the Steppe" (*Duch od Stepu*). Other poets of the so-called Ukraine school, which has been so well inspired by the romantic legends of that part of Russia, are Thomas or Timko Padoura (who also wrote in the Malo-Russian, or Little-Russian language), Alexander Groza, and Thomas Olizarowski. For many of the original songs and legends we must turn to the work of Messrs. Antonovich and Dragomanoff. Bogdan Joseph Zaleski was born in 1802 in the Ukraine village, Bohaterka. In 1820 he was sent to the university of Warsaw, where he had Goszczynski as a fellow-student. Since 1830 he has resided in Paris. Besides the longer poem previously mentioned, he is the author of many charming lyrics in the style of the Little-Russian poems, such as Shevchenko has written in that language. Michael Grabowski (1805–1863) belongs also to this school by his fine *Melodies of the Ukraine*. A poet of great vigor was Stephen Garczynski (1806–1833), the friend of Mickiewicz, celebrated for his *War Sonnets* and his poem entitled *The Deeds of Wactow*.

Among later authors, some of whom still survive, may be mentioned Wincenty Pol, born in 1807 at Lublin. He wrote a fine descriptive work, *Obrazy z Życia i Podróży* ("Pictures of Life and Travel"), and also a poem, *Piesm o Ziemi Naszej* ("Song of our Land"). For about three years from 1849 he was professor of geography in the university of Cracow. In 1855 he published *Mohort*, a poem relating to the times of Stanislaus Poniatowski. Ludwik Władysław Kondratowicz (who wrote chiefly under the name of Syrokomla) was born in

1823 in the government of Minsk. His parents were poor, and he received a meagre education, but made up for it by careful self-culture. One of his most remarkable poems is his *Jan Deborog*, in which like Mickiewicz, he has well described the scenery of his native Lithuania. He everywhere appears as the advocate of the suffering peasants, and has consecrated to them many beautiful lyrics. In Kaczowski the Poles have a novelist who has treated many periods of their history with great success. His sympathies, however, are mostly aristocratic, though modified by the desire of progress. An important writer of history is Karl Szajnocha, born in Galicia of Czech parents in 1818. He began his labors with *The Age of Casimir the Great* (1848), and *Bolesław the Brave* (1849), following these with *Jadwiga and Jagiello*, in three volumes (1855–1856),—a work which Spasovich, in his Russian *History of Slavonic Literature*, compares in vigor of style and fulness of color with Macaulay's *History of England* and Thierry's *Norman Conquest*. Our author was still further to resemble the latter writer in a great misfortune; from overwork he lost his sight in 1857. Szajnocha, however, like Thierry and the American Prescott, did not abandon his studies. His excellent memory helped him in his affliction. In 1858 he published a work in which he traced the origin of Poland from the Varangians (*Lechicki początek Polski*), thus making them identical in origin with the Russians. He began to write the history of John Sobieski, but did not live to finish it, dying in 1868, soon after completing a history of the Cossack wars, *Dwa lata dziejów naszych* ("Two Years of Our History"). A writer of romances of considerable power was Joseph Korzeniowski, tutor in early youth to the poet Krasinski, and afterwards director of a school at Kharkoff. Besides some plays now forgotten, he was author of some popular novels, such as *Wedrówki oryginalne* ("Tours of an Original"), 1848; *Garbaty* ("The Hunchback"), 1852, etc. He died at Dresden in 1863. But the most fertile of Polish authors beyond all question is Kraszewski¹ (born in 1812). His works constitute a library in themselves; they are chiefly historical novels, some of which treat of early times in Poland and some of its condition under the Saxon kings. Up to 1879, when he celebrated the fiftieth anniversary of his commencing authorship, he had written two hundred and fifty separate works in four hundred and forty volumes. One of the most popular of his novels is *Jermota the Potter*, a pathetic and noble story, which much resembles George Eliot's *Silas Marner*, but appeared in 1857, some time before the publication of that work. A charge of treason was recently brought against Kraszewski by the German Government, and he is now (1885) undergoing a sentence of imprisonment at Magdeburg. Among the various works of Kraszewski may be mentioned an interesting one on Lithuania (*Litwa*), which contains many valuable accounts of Lithuanian customs; perhaps, however, the historical and philological parts of the work are not always very critically treated. He is the author of two volumes of poetry. As lyrical poets may also be mentioned Jachowicz, Jaśkowski, author of a fine poem *The Beginning of Winter*, Wasilewski, and Holowinski, archbishop of Moghileff (1807–1855), author of religious poems. The style of poetry in vogue in the Polish parts of Europe at the present time is chiefly lyrical. Other writers deserving mention are Cornelius Ujejski (born in 1823), the poet of the last revolt of 1863; Theophilus Lenartowicz (born 1822), who has written some very graceful poetry; Sigismund Milkowski (born in 1820), author of romances drawn from Polish history; for the novel of the school of Sir Walter Scott still flourishes vigorously among the Poles. Among the very numerous writers of romances may be mentioned Henry Rzewuski (1791–1866); Joseph Dzierzkowski wrote novels on aristocratic life, and Michael Czajkowski tales of adventure; Valerius Wielogłowski (1865) gave pictures of country life. Of course at the head of all writers in this department must be considered the unfortunate Kraszewski.

In 1882 the Poles lost, in the prime of life, a very promising historian Sujski (born in 1835), and also Schmitt, who died in his sixty-sixth year. Sujski commenced his literary career in 1859 with poems and dramas; in 1860 appeared his first historical production, *Rent oka na Historję Polski* ("A Glance at Polish History"), which attracted universal attention; and in 1862 he commenced the publication in parts of his work *Dzieje Polski* ("The History of Poland"), the printing of which ceased in 1866. The value of this book is great both on account of the research it displays and its philosophical and unprejudiced style. One of the last works of Sujski, written in German, *Die Polen und Ruthenen in Galizien*, attracted a great deal of attention at the time of its appearance. Schmitt got mixed up with some of the political questions of the day—he was a native of Galicia and therefore a subject of the Austrian emperor—and was sentenced to death in 1846, but the penalty was

¹ [Joseph Ignatius, died March 20, 1887, an exile in Geneva, by the government censor.—AM. ED.]

commuted into imprisonment in Spielberg, whence he was released by the revolution of 1848. In 1863 he took part in the Polish rebellion, and was compelled to fly to Paris, whence he only returned in 1871. His chief works are *History of the Polish People from the Earliest Times to the year 1763* (1854), *History of Poland in the 18th and 19th Centuries* (1866), and *History of Poland from the time of the Partition* (1868), which he carried down to the year 1832. In opposition to the opinion of many historians, his contemporaries, that Poland fell through the nobility and the diets, Schmitt held (as did Lelewel) that the country was brought to ruin by the kings, who always preferred dynastic interests to those of the country, and by the pernicious influence of the Jesuits. Adalbert Kętrzyński, who succeeded Bielowski in 1877 in his post of director of the Ossoliński Institute at Lemberg, is the author of some valuable monographs on the history of Poland. He was born in 1838. Kasimir Stadnicki has treated of the period of the Jagiellons; and Szaraniewicz, professor at the university of Lemberg, has written on the early history of Galicia. Thaddeus Wojciechowski has published a clever work on Slavonic antiquities. Xavier Liske, born in 1838, and now professor of universal history at Lemberg, has published many historical essays of considerable value, and must be a linguist of great attainments, as separate works by him have appeared in the German, Polish, Swedish, Danish, and Spanish languages. The "Sketch of the History of Poland" (*Dejeje Polskie w Zarysie*) by Michael Bobrzyński, born in 1849 in Cracow (where he is professor of Polish and German law), is a very spirited work, and has given rise to a great deal of controversy on account of the opposition of many of its views to those of the school of Lelewel. Vincent Zakrzewski, now professor of history at Cracow, has written some works which have attracted considerable attention, such as *On the Origin and Growth of the Reformation in Poland*, and *After the Flight of King Henry*, in which he describes the condition of the country during the period between that king's departure from Poland and the election of Stephen Batory. Smółka has published a history entitled *Mieszko the Elder and his Age*. Władysław Wisłocki has prepared a catalogue of manuscripts in the Jagiellon library at Cracow. Dr. Joseph Casimir Plebanski is now editor of the *Biblioteka Warszawska*, a very valuable literary journal which stands at the head of all works of the kind in Poland. He has also written a dissertation (in Latin) on the *liberum veto*, which puts that institution in a new light. Felix Jezierski, the previous editor of the above-mentioned journal, published in it translations of parts of Homer, and is also the author of an excellent version of *Flaubert*.

The history of Polish literature has not been neglected. We first have the early history of Felix Bentkowski (1781-1852), followed by that of Michael Wiszniewski (1794-1865), which, however, only extends to the 17th century, and is at best but a quarry of materials for subsequent writers, the style being very heavy. A "History of Eloquence" (*Historia Wymowy w Polsce*) was published by Karl Mecherzynski. An elaborate history of Polish literature is now in course of preparation by Anton Matecki, who is the author of the best Polish grammar (*Gramatyka Historyczno-Porównawcza Języka Polskiego*, 2 vols., Lemberg, 1879). The Polish bibliography by Karl Estreicher, now director of the Jagiellon library at Cracow, is a work of the highest importance. One of the most active writers on Polish philology and literature is Władysław Nehring, whose numerous contributions to the *Archiv für Slavische Philologie* of Professor Jagie entitle him to the gratitude of all who have devoted themselves to Slavonic studies. Władimir Spasowicz, a lawyer of St. Petersburg, has assisted Pipin in his valuable work on Slavonic literature. The lectures of Professor Cybulski (ob. 1867) on Polish literature in the first half of the 19th century are written with much spirit and appre-

ciation. The larger poetical works which appear during that time are carefully analyzed.

In recent times many interesting geological and anthropological investigations have been carried on in Poland. In 1868 Count Constantine Tyszkiewicz published a valuable monograph on the *Tombs of Lithuania and Western Ruthenia*. A diligent searcher for antiquities is Prof. Joseph Łepkowski of Cracow, who has greatly enriched the archaeological museum of his native city.

In philosophy the Poles (as the Slavs generally) have produced but few remarkable names. Goluchowski, the brothers Andrew and John Sniadecki, the latter of whom has gained a reputation almost European, Bronisław, Trenowski, Karol Liebelt, and Joseph Kremer deserve mention. August Cieszkowski has written on philosophical and economic subjects. Moritz Straszewski, the present professor of philosophy at the university of Cracow, has also published some remarkable works.

Mention has already been made of the poetess Elizabeth Druzbicka. Female writers are not very common among Slavonic nations. Perhaps the most celebrated Polish authoress was Klementina Hoffmann, whose maiden name was Tanska, born at Warsaw in 1798. She married Karl Boromäus Hoffmann, and accompanied her husband, in 1831, to Passy near Paris, where she died in 1845. Her novels still enjoy great popularity in Poland. Of the poetesses of later times Gabriele Narzyssa Zmichowska (1825-1878), Maria Ilnicka, translator of Scott's *Lord of the Isles*, and Jadwiga Łuszczewska may be mentioned.

A poet of considerable merit is Adam Asnyk, born in 1838. In his poetry we seem to trace the steps between romanticism and the modern realistic school, such as we see in the Russian poet Nekrasoff. In some of the flights of his Muse he reminds us of Słowacki, in the melody of his verse of Zaleski. Besides showing talent as a poet, he has also written some good plays, as "The Jew" (*Zyd*), *Cola di Rienzi*, and *Kiejstut*. Other living poets worthy of mention are Zagorski, Czerwinski, and Maria Konopnicka, who has published two volumes of poems that have been very favorably noticed. Mention must also be made of Bafucki, born at Cracow in 1837, and Narzymiski (1839-1872), who was educated in France, but spent part of his short life in Cracow, author of some very popular tales.

The four centres of Polish literature, which, in spite of the attempts which have been made to denationalize the country, is fairly active, are Cracow, Posen, Lemberg, and Warsaw. A few years ago a cheap edition of the leading Polish classics, well adapted for dissemination among the people, was published under the title of *Biblioteka Polska*, at Cracow, which shows a great deal of vitality and is an interesting city. Not only are the professors of its university some of the most eminent living Poles, but it has been chosen as a place of residence by many Polish literary men. The academy of sciences, founded in 1872, celebrated the bicentenary of the raising of the siege of Vienna by Sobieski by publishing the valuable *Acta Joannis III. Regis Poloniae*. Some good Polish works have been issued at Posen, but it is becoming extremely Germanized, and no part of the original kingdom of Poland has undergone so much change as this. At Lemberg, the capital of Austrian Galicia, there is an active Polish press. Here appeared the *Monumenta Poloniae Historica* of Bielowski, previously mentioned; but Polish in this province has to struggle with the Red-Russian or Ruthenian, a language or dialect which for all practical purposes is the same as the Southern or Little Russian. At Warsaw, since the last insurrection, the university has become entirely Russianized, and its *Transactions* are published in Russian; but Polish works of merit still issue from the press,—among others the leading Polish literary journal, *Biblioteka Warszawska*. (W. R. M.)

POLAND, RUSSIAN. After the three dismemberments of the old kingdom, the name of Poland was chiefly retained by the part of the divided territory annexed to Russia. Since the insurrection of 1863, however, the name "kingdom of Poland" has disappeared. Thenceforward this portion of the Russian empire is referred to in official documents only as the "territory of the Vistula," and later on as the "Vistula government." Nevertheless the geographical position of Russian Poland, its ethnographical features, its religion, and its traditions differentiate it so widely from the remainder of the Russian empire that the name of Poland still survives in current use. The area of this territory is 49,157 square miles, and the popu-

lation exceeds 7,300,000. See **RUSSIA**, and map accompanying that article.

Projecting to the west of Russia in a wide semicircle between Prussia and Austria, it is bounded on the N. by the provinces of western and eastern Prussia, on the W. by Posen and Prussian Silesia, on the S. by Galicia, and on the E. by the Russian governments of Volhynia, Vilna, Grodno, and Kovno. It consists for the most part of an undulating plain, 300 to 450 feet above the sea, which joins the lowlands of Brandenburg in the west, and the great Surface. plain of central Russia in the east. A low swelling separates it from the Baltic Sea; while in the south it gradually rises to a range of plateaus which impercep-

tibly blend with the spurs of the Carpathians. These plateaus, with an average height of from 800 to 1000 feet, occupy all the southern part of Poland. They are mostly covered with beautiful forests of oak, beech, and lime, and are deeply cut by the valleys of rivers and numerous streams, some being narrow and craggy, and others broad, with gentle slopes and marshy bottoms. Narrow ravines intersect them in all directions, and their surface often takes, especially in the east, the *puszcz* character,—in other words, that of wild, unpassable, woody, and marshy tracts. In these tracts, which occupy the southeastern corner of Poland, and are called Podlasie, the neighborhood of the Polyesie of the Pripiet is felt. The Vistula, which borders these plateaus on the southwest, at a height of 700 to 750 feet, has to penetrate them before finding its way to the great plain of Poland, and thence to the Baltic. Its valley divides the hilly tracts of Poland into two parts,—the Lublin heights in the east, and the Sedomierz (Sandomir), or central, heights in the west. These last are diversified by several ridges which run east-southeast, parallel to the Beskides, the highest of them being those of the “Bald” or “Holy Cross Mountains” (Łysogórski, or Świętokrzyski), two summits of which respectively reach 1813 and 1961 feet above the sea. Another short ridge, the Chęciński hills, follows the same direction along the Nida river, reaching 1135 feet at Zamkowa Góra. South of the Nida, the Olkusz Hills, already blended with spurs of the Beskides, fill up the southwest corner of Poland, reaching 1473 feet at Podzamcze, and containing the chief mineral wealth of the country; while a fourth range, from 1000 to 1300 feet high, runs northwest past Częstochowo, separating the Oder from the Warta. In the north, the plain of Poland is bordered by a flat and broad swelling, 600 to 700 feet above the sea, dotted with lakes, and recalling the lake regions of north-western Russia. Its gentle southern slopes occupy the northern parts of Poland, while the province of Suwałki, projecting as a spur towards the northeast, extends over the flat surface of this swelling. Wide tracts covered with sands, marshes, peat-bogs, ponds, and small lakes, among which the streams lazily flow from one marsh to another, the whole being covered with poor pine-forests and a scanty vegetation, with occasional patches of fertile soil—such are the general characters of the northern border-region of the great plains of central Poland.

These plains extend in a broad belt, 150 miles wide, from the Oder to the upper Niemen and the marshes of Pinsk, gently sloping towards the west, and slowly rising towards “the woods” of Volhynia and Grodno. Few hills raise their flat tops above the surface, the irregularities of which for the most part escape the eye, and can be detected only by levellings. As far as the eye can see, it perceives a plain; and each hill, though but a few hundred feet above its surface, is called a “góra” (mountain). The rivers flow in broad, level valleys, only a few hundred or even only a few dozen feet lower than the watersheds; they separate into many branches, enclosing islands, forming creeks, and covering wide tracts of land during inundations. Their basins, especially in the west, are mixed up with one another in the most intricate way, the whole bearing unmistakable traces of having been in recent geological and partly in historical times the bottom of extensive lakes, whose alluvial deposits now yield rich crops. The fertility of the soil and the facility of communication by land and by water have made this plain the very cradle of the Polish nationality, and every furlong of it to the Pole is rich in historical memories. The very name of Poland is derived from it,—Wielkopolska and Wielkopole being the Slavonian for the great plain and its inhabitants.

Russian Poland belongs mostly, though not entirely, to the basin of the Vistula—its western parts extending into the upper basin of the Warta, a tributary of the Oder, and its northeast spur

(Suwałki) penetrating into the basin of the Niemen, of which it occupies the left bank. For many centuries, however, the Poles have been driven back from the mouths of their rivers by the German race, maintaining only the middle parts of their basins.

The chief river of Poland, and the very cradle of the Polish nationality, is the Vistula (Pol. *Wista*), the *Vandalus*, *Visula* and *Istula* of antiquity. It has a length of 620 miles, and a drainage area of 72,000 square miles. It rises in Galicia, in the Beskides, 3675 feet above the sea, where the Black and White Vistulas unite. Flowing first northeast, in an elevated valley between the Beskides and the Sandomir heights, it separates Russian Poland from Galicia, and already at Cracow has a breadth of 90 yards. It enters Russian Poland at Zawichost, 473 feet above the sea. After having received the San, it turns north, traversing for some 35 miles a broad valley deeply cut through the plateaus of southern Poland. This valley reaches at several places a width of 10 miles between the limestone crags which border it on both sides, the space between being occupied by two alluvial terraces, where the river winds freely, divides into several branches, and frequently changes its bed. Here it has a speed of 8 feet per second, with a gradient of 1.3 to 1.5 feet per mile, and a depth ranging from 4 to 20 feet. About Jusefow (51° N. lat.) it enters the great central plain, where it flows north and west-northwest between low banks, with a breadth of 1000 yards. Its inundations, dangerous even at Cracow, become still more so in the plain, where the accumulations of ice in its lower course obstruct the outflow, or the heavy rains in the Carpathians raise its level. Dams 20 to 24 feet high, are maintained at great expense by the inhabitants for 60 miles, but they do not always prevent the river from inundating the plains of Opole and Koźienic, the waters sometimes spreading as far as 150 miles to the east. Below Warsaw (267 feet) it frequently changes its bed, so that, for example, Plock (180 feet), which formerly was on its left bank, is now on the right. About Thorn it enters Prussia, and a few miles below this town it finds its way through the Baltic ridge flowing in a northeast direction and entering the Baltic Sea in the Frische-Haff at Daatzic. On the whole, it is what the physical geographer would call a “young” river, which is still excavating its bed, and probably on this account few towns of importance are situated on the Vistula in Russian Poland, the principle being Sedomierz, Warsaw and Plock, and the fortresses of Ivangorod and Novogeorgievsk (Modlin), while very many small towns have sprung up within short distances from its course. It is navigable almost from Cracow for small boats and rafts, which descend it at high water. Real navigation begins, however, only below its confluence with the Wieprz, the middle and lower Vistula being the chief artery for the traffic of Poland. Thousands of rafts and boats of all descriptions descend every year, with cargoes of corn, wool, timber and wooden wares, giving occupation to a large number of men. Steamers ply as far as to Sedomierz.

The Vistula receives many tributaries, the most important being the San, the Wieprz and the Bug on the right, and the Nida and the Pilica on the left. The San (220 miles) rises in Galicia, in the same part of the Carpathians as the Dneister, and flows northwest, close to the southern frontier of Poland; it is navigable downwards from Dynow, and is ascended by boats as far as Yaroslaw in Galicia. The Wieprz (180 miles) is the chief artery of the Lublin government; it flows northwest past Lublin and Lubartow, joining the Vistula at Ivangorod. It is navigable for small boats and rafts for 105 miles from Krasnostaw. The Bug, which describes a wide curve concentric with those of the middle Vistula and Narew, rises to the east of Lwow (Lemberg) and flows north and west, past Hrubieszow, Chełm and Brest-Litowski, separating the Polish provinces of Lublin and Siedlce from Volhynia and Grodno. It joins the Vistula a few miles below its confluence with the Narew, some 20 miles below Warsaw, after a course of more than 675 miles. Only light boats (*galery*) are floated down this broad but shallow stream, whose flat and open valley is often inundated. Its great tributary, the Narew (150 miles), brings the forest-lands of Byetowezha into communication with Poland, timber being floated down from Surazh and light boats from Tykocin. The mountain-stream Nida waters the hilly tracts of Kielce, and, rapidly descending southeast, joins the Vistula close by the Opatowiec custom-house. The Pilica rises in the southwestern corner of Poland, and flows for 135 miles north and east in a broad, flat, sandy or marshy valley, of evil repute for its unhealthiness; it joins the Vistula at Mniszew, 30 miles above Warsaw.

The Warta (450 miles) rises in the Częstochowo hills, 900 feet above the sea, and flows north and west past Sieradz (448 feet) and Koło. Below Częstochowo it waters a flat low-

land, whose surface rises only from 2 to 5 feet above the level of the river; and the inhabitants have a constant struggle to keep it to its bed; the country is, however, so low that every spring an immense lake is formed by the river at the mouth of the Ner; as regards its right hand tributaries, it is almost impossible to define them from those of the Bzura, tributary of the Vistula, amidst the marshy grounds where both take their origin. The Warta turns west at Koto and leaves Poland at Pyzdry in the government of Kalisz; it serves to convey timber to Prussia.

The Niemen, which has a total length of 500 miles and a basin of 40,000 square miles, flows along the northeast frontier of Poland, from Grodno to Yurburg, separating it from Lithuania. Already 70 yards wide at Grodno, it advances northwards in great windings, between limestone hills covered with sand, or amidst forests, past numerous ruins of castles, or *keorgans*, which witness the battles that have been fought for its possession. The yellowish sandy plains on its left allow only the cultivation of oats, buckwheat and some rye. The river flows so slowly below Kovno as to seem almost stationary; it often changes its bed, and, notwithstanding repeated attempts to regulate it, offers great difficulties to navigation. Still, large amounts of corn, wool, and timber are floated down, especially after its junction with the Black Hancza, giving occupation to about 90,000 men. A little above Kovno the Niemen turns west, and after having received the Wilja from the right, it attains a width of nearly 500 yards. At Yurburg it enters eastern Prussia, and reaches the Baltic Sea at the Kurische-Haff. Of its tributaries in Poland, only the Hancza Czarna and the Szeszupa, which winds through the province of Suwałki, are worthy of mention.

Lakes. Lakes are numerous in the province of Suwałki, amounting there to over five hundred; but the largest of them, Wigry, traversed by the Hancza, covers only 11,000 acres. They are mostly concealed amid thick coniferous or birch forests, and their waters stretch with undefined banks amidst marshes, sands, or layers of boulders thickly covered with moss. Another group of some one hundred and twenty small lakes is situated in the basin of the Warta (north part of Kalisz), the largest being Gopło, 18 miles long and 100 feet deep, surrounded by many smaller lakes, and receiving the Notec river. It was much larger even within historical times, and was well known from being situated on the highway from the Adriatic, *via* Kofo on the Oder, to the basin of the Vistula.

Though navigable for a few months only, the rivers of Poland have always been of considerable importance for the traffic of the country, and this importance is further increased by several canals connecting them with Russian and German rivers. The Niemen is connected with the Dnieper by the Oginski Canal, situated in the Russian government of Minsk. The Dnieper-and-Bug (Horodecki, Brzeski, also Królewski) Canal in Grodno connects the Mukhavets, tributary of the Bug, with the Pina of the basin of the Pripiet, that is, the Dnieper with the Vistula. The Vistula is connected also with the Oder by the Bydgoski or Bromberg Canal in Prussia, which connects the Brda, of the basin of the Vistula, with the Notec, or Netze, tributary of the Warta. All these canals are, however, beyond Russian Poland. In Poland proper, the Angustowski Canal connects the Vistula with the Niemen, by means of the Hancza, Netta, Biebrz and Narew. Another canal, to the west of Łęczyca, connects the Bzura, a tributary of the Vistula, with the Ner and Warta; and the bed of the former has recently been altered so as to obtain regular irrigation of the rich meadows extending along its banks.

With the exception of its southern parts, Poland is built up almost exclusively of Secondary and Tertiary formations, covered with a thick sheet of Quaternary deposits. The non-schistous rocks

are represented only by a small patch of porphyries near Chęcin, and another of basalts at the castle of Tęczyński. Small deposits of quartzites in the Dyminski Hills, characterized by the *Orthis kielecensis*, Röm., which formerly were considered as Devonian, belong to the Silurian as also a few dolomites appearing from beneath the Devonian Old Red Sandstone and limestones. The last two cover wide tracts in the province of Kielce, and in the district of Będzin, on the Silesian frontier. The Devonian limestones of Kielce, which contain the *Orthis striatula*, *Spirifer inflatus*, *Atropa reticularis*, *A. desquamata*, *Leptæna interstitialis*, *Bronteus flabellifer*, *Spirifer verneuli*, and *Rhynchonella cuboides*; thus exhibit a fauna closely akin to that of the Devonian of Germany and Belgium, or the lowest part of the Upper Devonian—the so-called “*Cuboides*-Schichten.” The hard sandstone of Dombrowa, Brzezina, etc., with *Chonetes sarculata*, *Spirifer paradoxus*, *S. cultrijugatus*, and *Pterinea pail-*

letei, is certainly Lower Devonian. This formation contains the chief mineral resources of Poland.

The Carboniferous formation appears in the Olkusz and Będzin districts. It consists of sandstones and clays, with layers of coal 30 feet thick. The Permian is represented by porphyric tuffs in the Olkusz district, “*Zechstein*” characterized by *Productus horridulus*, Sow., at Kielce, and a breccia consisting of Devonian boulders. The Trias is widely spread. It consists of variegated sandstones, characterized by *Myophoria costata*, occurring extensively in the governments of Kielce and Radom, yielding a fine building stone. The red sandstones north and west of Kielce, considered as Permian on Pusch's map, probably belong to the same formation, like the red sandstones in the most northern parts of the Kielce mountains. The “*Muschelkalk*” appears in the districts of Olkusz and Będzin, as also in the Kielce mountains, and has great importance, containing as it does zinc, tin and iron ores. The “*Keuper*” in the governments of Kielce, Piotrków, and Radom consists of sandstones, dolomites, and limestones, and contains brown coal and iron ores.

The Jurassic formation is widely spread; in southwest Poland it occupies the space from Olkusz to Wielun, and consists of brown and white “*Jura*,” the whitish crags of which give pleasing landscapes at Ojcowo and on the Pilica. The Oolite crags of Ojcowo contain numerous caverns, renowned for their bone deposits, worked out for manure, and for their numerous and remarkable Quaternary fossils. That of Jerzmanowice, close by Ojcowo, the largest of the series, has a length of 750 feet. The Cretaceous formation, which covers very large tracts throughout Poland, consists of lower series of sandstones, and of an upper series containing chalk and limestone, and yielding very fertile marls. They are covered with Tertiary limestones and gypsums, which, together with Cretaceous deposits, cover nearly the whole of the central plain and the northern provinces. The layers of sulphur at Kielce, 7 to 70 feet thick, belong to the Tertiary.

The whole is covered with Quaternary deposits, reaching at several places a very great thickness. They are chiefly made up of boulder clay containing Scandinavian erratics of all sizes up to 5 and 7 feet in diameter. The Baltic ridge is quite covered with them, their southern limit extending to 51° N. lat., or perhaps even to 50°, as the longitudinal valleys of the Kielce hills also contain layers of Scandinavian boulders. Diluvial and alluvial sands and clays cover the glacial deposits; and everywhere in Poland one meets with remains of extensive lakes that filled up all depressions of the country during the post-Glacial period. Thick peat-bogs are being formed in the moister depressions, and cover an aggregate surface of no less than 2,800,000 acres.

In these lacustrine deposits numerous traces of prehistoric man have been found, but the old lake beds still await a more thorough exploration. The bone caves at Ojcowo have yielded rich finds of extinct mammals, thirty-two species of which are familiar to explorers of British caverns; the cave-bear alone has yielded full four thousand canine teeth, while the mammoth, the woolly rhinoceros, the cave hyæna, and especially the reindeer, are represented by numerous remains. The bones of extinct mammals have been found in association with very numerous relics of man, some of which are most probably Palæolithic, while the great number belong to the Neolithic period,—those cave-inhabitants being in some instances dolichocephalic, like those of the shores of post-Glacial lakes, and in others mesocephalic.

Southern Poland is rich in minerals, especially in the Kielce mountains and the region adjacent to Prussian Silesia. The Devonian sandstones. Minerals. contain malachite ores at Medziana Góra, near Kielce, and copper has been worked there since the 15th century. In the years 1816–1826, 65,000 cwt. of copper ore were extracted but the mines are now neglected. The brown iron ores, also Devonian, of Kielce, and especially those of Daleszyc, contain no less than 40 per cent. of iron. The Triassic zinc ores of the Olkusz district, more than 50 feet thick at Bolstaw, contain 8 to 14 per cent., sometimes 25 per cent., of zinc; and in 1879, 2,866,000 cwt. of ore were extracted from nine pits, yielding about 100,000 cwt. of zinc. The tin ores of Olkusz, also Triassic, are still more important, and were extensively wrought as early as the 16th century, notwithstanding the difficulties arising from the presence of water; they are reported to have then yielded more than 35,000 cwt. per annum. In 1878 the very fluctuating yield reached only 8,960 cwt. Brown iron ores appearing in the neighborhood of Będzin as lenses 55 feet thick, and containing 25 to 33 per cent. of iron accompany the Triassic zinc ores. Spherosiderites and brown iron ores are also widely spread in the “*Keuper*.” Sulphur is wrought at Czarkowa, in the district of Pińczow; the de-

posits, which contain 25 per cent. of sulphur, reach a thickness of 7 to 70 feet, and the amount of sulphur is estimated at 1,300,000 cwt.

Carboniferous coal is spread in southwest Poland over a surface of about 200 square miles in the districts of Będzin and Olkusz, which are estimated to contain 732,000,000 cubic yards of coal. The Triassic brown coal, which appears in the Olkusz district in layers 3 to 7 feet thick, has lately been worked out, the single pit of St. John yielding in 1879 204,200 cwt. of coal. Of other mineral produce, chalk exported from Lublin, a few quarries of marble, and many of building stones are worthy of notice. Mineral waters are used medicinally at Ciechocin and Nałęczow.

With the exception of the Lysa Góra hilly tracts (Kielce and South Radom), which lie within the isotherms of 41° and 42°, Poland is situated between the isotherms of 42° and 46°. The isotherms and isoclims (i. e., lines of equal mean summer and winter temperature) crossing one another at right angles, and the former running east-northeast, Poland is included between the isotherms of 64° and 61° and the isoclims of 35.7° and 39.2°. The prevailing winds are westerly, with north-northeast and south winds in autumn and winter, and east winds in spring. The number of rainy and snowy days varies from 152 to 158, increasing towards the Baltic, with an average of 21.7 to 23.6 inches of rainfall in central Poland, which figures slowly increase also towards the south on account of the proximity of the Carpathians, where they reach 30.3 inches. Of the above amounts, about 17 per cent. fell in spring, 29 per cent. in summer, 21 per cent. in autumn, and 33 per cent. in winter. Owing to this distribution the snow-covering in Poland is not very thick, and the spring sets in early. Still frosts, lowering the thermometer to -4° and -22° Fahr. are not uncommon, and the rivers are covered with ice for two and a half to three months,—the Warta being under ice for 70 and 80 days, the Vistula at Warsaw for 80 days and (exceptionally) even for 116, and the Nieman for 100 (exceptionally for 140).

The following averages may help to give a more adequate idea of the climate of Poland:

	Warsaw.	Vilna.
Earliest frost.....	Oct. 18	Oct. 17
Latest frost.....	Mar. 15	Mar. 25
Average maximum temperature...	85.7°	85.1°
Average minimum "	1.7°	-9.6°
Absolute maximum "	95.5°	89.3°
Absolute minimum "	37.6°	-39.0°
Bright days.....	40	23
Cloudy days.....	154	175
Annual rainfall (total).....	22.8 in.	7.6 in.
Rainfall—November to March.....	6.7 in.	4.7 in.
Prevailing winds in January.....	S.E.	S.
" " in July.....	W.	W.
" " during the year..	S.E.	W.

The flora of Poland is more akin to that of Germany than to that of Russia, several middle European species finding their northeast limits in the basin of the Nieman or in the marshes of Lithuania.

Coniferous forests consisting mostly of pine (*Pinus sylvestris*), and birch cover large tracts in Mazovia, extending over the Baltic lake-ridge, reaching southwards as far as the junction of the Bug with the Narew, and joining in the southeast the "Polysie" of the Pripet. The pine covers also the Lysa Góra hills and those on the San. The larch (*Larix europæa*), which three centuries ago covered large tracts has almost entirely disappeared; it is now met with only in the Samsonowski forests of Sandomeria. The *Pinus Cembra* is only remembered, as also the *Taxus baccata*, which has but a few representatives in Sandomerian forests, on the Pilica, on the *puszczas* of Ostrołęka, and in the Preny forests on the Nieman. The *Picea obovata* is cultivated.

Of leaf-bearing trees, the common beech (*Fagus sylvatica*) is the most typical of the Polish flora; it extends from the Carpathians to 52° N. lat., and three degrees farther north in small groups or isolated specimens; the confluence of the Bug and Narew may still be regarded as its eastern limit. The white beech (*Carpinus Betulus*), the aspen (*Populus tremula*), and two elms (*Ulmus campestris*, *U. effusa*) are found nearly everywhere, mingled with other trees in forests. The same is true with regard to the lime-tree (*Tilia parvifolia*), which appears in groves only in the east (Nieman, Pripet, Lublin). It is the most popular tree with the Poles, as the birch with the Russians; judgment of old was pro-

nounced under its shade, and all the folk-lore songs repeat its name. The oak—a highly venerated tree in Poland, though not so much as in Lithuania—grows in forests only on the most fertile patches of land, but it is of common occurrence in conjunction with the beech, elm, etc. The maples (*Acer platanoides* and *A. pseudoplatanus*) are somewhat rare; the black alder (*Alnus glutinosa*) covers the banks of the rivers and canals, and the *Alnus incana* is common. The willow, and the orchard trees—apple, pear, plum, and cherry—are cultivated everywhere.

The flora of Poland contains 12 per cent. of *Compositæ*, 6 per cent. of *Leguminosæ*, 2 per cent. of *Labiata*, 4 per cent. of *Umbellifera*, 5 per cent. of *Crucifera*, and 2 per cent. of *Conifera*.

The wheat frontier coincides very nearly with that of the leaf-bearing forests. It yields good crops on the fertile tracts of Sandomeria and Lublin, and on the plains of the Vistula and Warta, but does not thrive very well beyond 52° N. lat. Rye, oats, barley, buckwheat, and hemp are cultivated everywhere, and flax in the east; hops are very common, and tobacco-culture has been begun in the south. Some attempts in sericulture have been made with success.

The fauna of Poland belongs to the middle European zoological group; within the historical period it has lost such species as formerly gave it a Fauna. subarctic character. The reindeer now occurs only as a fossil; the sable mentioned in the annals, has migrated eastwards; the wild horse, also, described by the annals as intermediate between the horse and the ass—probably like the recently discovered *Equus przewalskii*—is said to have been met with in the 13th century in the basin of the Warta, and two centuries later in the forests of Lithuania. The wild goat, bison, and elk have migrated to the Lithuanian forests. The lynx and beaver have also disappeared. The brown bear continues to haunt the forests of the south, but it is becoming rarer in Poland; the wolf, the wild boar, and the fox are most common throughout the great plain, as also the hare and several species of *Arvicola*. The mammals in Poland, however, do not exceed fifty species. The avi-fauna, which does not differ from that of central Europe, is represented by some one hundred and twenty species, among which the singing birds (*Dentirostræ* and *Conirostræ*) are the most numerous. On the whole Poland lies to the westward of the great line of passage of the migratory birds, and is less frequented by them than the steppes of southwest Russia. Still, numerous aquatic birds breed on the waters of the Baltic lake-region.

The population of Poland, 6,193,710 in 1871, reached 7,319,980 in 1881, showing an increase of 1.8 per cent. per annum during the ten years, and an average of 15 persons per square mile. Of these 17 per cent lived in towns. They were distributed as follows:

Governments.	Area, Square Miles.	Total Population, 1881.	Urban Population.	Per Square Mile.
Kalisz.....	4,391	765,403	96,848	17.4
Kielce.....	3,897	622,842	38,493	16.0
Łomża.....	4,667	538,588	51,554	11.5
Lublin.....	6,499	860,382	78,867	13.2
Piotrków.....	4,730	837,928	144,246	17.7
Płock.....	4,200	538,141	78,797	12.8
Radom.....	4,769	633,715	69,058	13.3
Siedlce.....	5,535	616,649	117,011	11.1
Suwałki.....	4,846	603,174	61,827	12.4
Warsaw.....	5,623	1,303,158	485,852	23.2
Total.....	49,157	7,319,980	1,222,553	14.9

The bulk of the population are Poles. During prehistoric times the basin of the Vistula seems to have been inhabited by a dolichocephalic race, different from the brachycephalic Poles of the present day; but from the dawn of history the Slavonians (Poles), mixed to some extent with Lithuanians, are found on the plains of the Vistula and Warta. The purest Polish type is found in the basin of the middle Vistula and in Posen; in the northeast there is a Lithuanian admixture, and in the southeast a Little Russian. The geographical domain of the Poles corresponds approximately with the limits of Russian Poland. Some 250,000 Lithuanians (277,000 or 284,000, according to other enumerations) occupy the north part of Suwałki, their southern limit being the Hancza river and the towns Sejno and Suwałki; while the Ruthenians (about 560,000 in 1873) appear in compact masses in the east and southeast, occupying the

whole space between the Bug and the Wieprz as far as Siedlce, as also the region between the upper Wieprz and the San. The White Russians number 27,000 in the north-east and east, and the Great Russians 12,000. The Poles extend but little beyond the limits of Russian Poland. In east Prussia they occupy the southern slope of the Baltic ridge (the Mazurs); and on the left bank of the lower Vistula they spread to its mouth (the Kaszubes). Westward they occupy a strip of land of an average breadth of 50 miles in Brandenburg, Posen, and Silesia, stretching down the Warta as far as Birnbaum (100 miles east of Berlin); and in the south they extend along the right bank of the Vistula in western Galicia to the San. In Russia they constitute, with Jews, Lithuanians, Ruthenians, and White Russians, the town population, as also the landed nobility and *szlachta*, in several provinces west of the Dwina and the Dnieper. Their numbers in these provinces may be seen from the following figures:

Governments.	Population (1867).	Number of Poles.	Percentage of Poles.	Probable No. of Poles in 1881.
Vilna.....	973,570	143,290	14.7	175,000
Podolia.....	1,946,760	233,650	12.0	269,000
Volhynia.....	1,643,270	172,405	10.5	215,000
Minsk.....	1,135,590	117,750	10.4	160,500
Grodno.....	958,850	89,850	9.3	112,700
Vitebsk.....	838,050	40,725	4.9	54,950
Kieff.....	2,144,280	71,640	3.3	87,650
Moghileff.....	908,860	26,115	2.9	32,700
Kovno.....	1,131,250	30,875	2.7	38,950
Courland.....	597,290	13,155	2.2	14,000
Smolensk.....	1,163,590	1,450	0.1	1,600
Total.....	13,441,360	940,905	7.00	1,162,050

According to the localities which they inhabit, the Poles take different names. They are called Wielkopolanie on the plains of middle Poland, while the name of Małopolanie is reserved for those on the Warta. The name of Łęczyzanie is given to the inhabitants of the marshes of the Ner, that of Kurpie to those of the Podlasie; Kujawiacy, Szlacy in Silesia, Górale in the Carpathians.

The Kaszubes, and especially the Mazurs, may be considered as separate stocks of the Polish family. The Mazurs (whose northern limits may be thus described—Przerosl in Suwałki, Goldap, Rastenburg, and Bischofsburg in Prussia, and Mława in Plock) are distinguished from the Poles by their lower stature, broad shoulders and massive structure, and still more by their national dress, which has nothing of the smartness of that of the southern Poles, and by their ancient customs; they have also a dialect of their own, containing many words now obsolete in Poland, and several grammatical forms bearing witness to the Lithuanian influence. They submit without difficulty to German influence, and already are Lutherans in Prussia. The language of the Kaszubes can also be considered as a separate dialect. The Poles proper are on the whole of medium stature (5 feet 4.6 inches), finely built, dark in the south and fair in the north, richly endowed by nature, inclined to deeds of heroism, but perhaps deficient in that energy which characterizes the northern races of Europe, and in that sense of unity which has been the strength of their present rulers.

The German element is annually increasing both in numbers and in influence, especially during the last twenty years. The Łódz manufacturing district, the Polish Birmingham, is becoming more German than Polish; and throughout the provinces west of the Vistula German immigration is going on at a steadily increasing rate, especially in the governments of Plock, Calisz, Piotrków, and Warsaw. It is estimated that a strip of land 35 miles wide along the Prussian frontier is already in the hands of Germans, whose advance is further favored by the rapid transference of landed property into German hands in Posen. In Russian Poland associations of four to six men, supported by German banks, purchase large numbers of properties belonging to the members of the Polish nobility who have been ruined since the last insurrection. No fewer than 30,736 German landholders, owning 5433 estates, were enumerated last year in the provinces west of the Vistula; while 13,714 foreign proprietors, farmers, and laborers (11,497 Prussians and 1914 Austrians) were at the same time owners of 1,857,900 acres, valued at 135,000,000 roubles (\$103,950,000). According to other statistics, the foreigners in Poland, mostly Germans, who remained foreign subjects,

numbered 170,000 in 1881 (5.15 per cent. of the population). Of these, 91,440 (families included) hold landed property to the amount of 2,605,500 acres, or 8.3 per cent. of the area of the kingdom. The aggregate number of Germans in Russian Poland, estimated at 370,000 in 1873, must now exceed 450,000, thus constituting about one-fifteenth of the population.

The Jews, who are found everywhere throughout Poland, are still more numerous, and must now exceed a million. They are nowhere agricultural; in the larger towns many of them are artisans, but in the villages they are almost exclusively engaged as shopkeepers, second-hand traders, dealers on commission, innkeepers, and usurers. In the country, both commerce and agriculture are in the hands of their intimately connected trading associations. Their relations with Poles and Ruthenians are anything but cordial, and "Jew-baiting" is of frequent occurrence. They are increasing much more rapidly than the Slavs.

The relative numbers of the various inhabitants of Poland may be seen from the following figures:

	According to Galkin (1868).	According to Rittich (1873).	Per cent.
Poles.....	3,900,580	4,375,840	68.4
Jews.....	764,950	860,330	13.4
Little Russians.....	428,380	505,960	8.5
White Russians.....	33,520	26,865	
Great Russians.....	11,065	12,155	
Germans.....	234,150	370,360	5.8
Lithuanians.....	277,050	241,150	3.8

The prevalent religion is the Roman Catholic, to which, in 1870, 4,596,956 out of a population of 6,034,430 belonged; at the same date 246,485 were adherents of the United Church, 327,845 were Lutherans, 34,135 were of the Greek Church, and 4926 Non-conformists. The Jews at the same date were reckoned (certainly an under-estimate) at 815,443, and the Mohammedans at 426. The number of followers of the United Church has much diminished since 1873, when they were compelled to join the Greek Church.

Since the last insurrection a series of measures have been taken to reduce the numbers of the Roman Catholic clergy in Poland; in 1883 there remained 1313 churches out of 1401, 1544 priests out of 2322, 10 monasteries out of 29, and 8 convents out of 30. One diocese (Podlasie) having been abolished, and a new one established at Kielce, while several bishops had been sent out of the country, the whole situation remained unsettled until 1883, when the pope recognized the new diocesan subdivisions introduced by the Russian Government. Poland is now divided into four dioceses (Warsaw, Sandomierz, Lublin, and Plock).

From remote antiquity Poland has been celebrated for the production and export of grain. Both, however, greatly declined in the 18th century; and towards the beginning of this century the peasants, ruined by their proprietors, or abandoned to the Jews, were in a more wretched state than even their Russian neighbors. Serfdom was abolished in 1807; but the liberated peasants received no allotments of land, and a subsequent law (1808) rendered even their transference from one landlord to another almost impossible; the old patrimonial jurisdictions were also retained. Compelled to accept the conditions imposed by the landlords, they had to pay rack-rents and to give compulsory labor in various forms for the use of land. Only a limited number were considered as permanent farmers, while nearly one-half of the peasants became mere *prolétaires*; in 1864 1,338,830 farmer peasants had ceased to have land rights at all. Pursuing a policy intended to reconcile the peasantry to Russian rule and to break the power of the Polish nobility, the Russian Government promulgated, during the outbreak in 1864, a law by which those peasants who were holders of land on estates belonging to private persons, institutions (such as monasteries and the like), or the crown were recognized as proprietors of the soil,—the state paying compensation to the landlords in bonds, and the peasants having to pay a yearly annuity to the state until the debt thus contracted had been cleared. The valuation of these allotments was made at a rate much more advantageous than in Russia, and the average size of holding reached 15 acres per family. Of those who held no land a number received it out of the confiscated estates of the nobility and monasteries. At the same time the self-government of the peasant was organized on democratic principles. The so-called "servitudes," however, that is, the right to pasture on and take wood from the landlord's estates, were maintained for political reasons,

becoming a source of great inconvenience both to landlords and peasants.

Whatever be the opinion held as to the intention of these reforms, there can be no doubt that they resulted in a temporary increase of prosperity, or at any rate an alleviation of the previous misery of the peasants. In 1864 there were 342,500 peasant families, holding an aggregate of 8,300,000 acres of land; but only 22,000 peasants, that is, less than one-half per cent. of the agricultural population, were proprietors, the remainder (218,500) being nobles, while 2,000,000 peasants were *cziniszewiki*, that is, tenants at will, and 1,338,000 had no land at all. In 1872 there were already 572,100 free peasant estates, occupying 13,000,000 acres. In ten years (1864-73) the area of cultivated soil had increased by 1,350,000 acres, while during the fourteen years 1845-59 its increase was only 540,000 acres. The crops, which stood in 1846-60 at an average of 9,360,000 quarters [74,880,000 bu.] of corn and 6,500,000 quarters [52,000,000 bu.] of potatoes, reached respectively 15,120,000 and 14,400,000 quarters [120,960,000 and 115,200,000 bu.]. The yearly increase, which was only 2.2 per cent. for corn and 1.3 per cent. for potatoes during the years 1846-60, became respectively 4.7 and 8.3 per cent. during the years 1864-75, and the average crop per head rose from 1.93 quarters [15.44 bu.] in 1850 to 2.52 [20.16 bu.] in 1872. The annual increase of horses, which formerly was 1 per cent., reached 2.7 per cent. in 1864-70, while the yearly increase of cattle remained almost stationary (1.2 per cent., against 1.1 per cent.). In fact, Poland had in 1870 only 37 head of cattle for each 100 persons, against 41 head in 1860. Another consequence of these measures was a notable decrease of crime, and a rapid increase of village primary schools, maintained by the peasants themselves.

It must be acknowledged, however, that the maintenance of the "servitudes" has become a serious evil. Moreover, the want of pasture-land, the want of money for improvements, quite insufficiently supplied by the joint-stock banks in the villages, and the very rapid increase in the price of land, from 50 roubles [\$38.50 silver roubles] per morgen (1.3835 acre) to 120 [\$92.40 silver roubles] and 250 roubles, [\$192.50] have all helped to lessen the benefits of the agrarian measures of 1864. The peasants are unable to purchase land proportionately with the increase of population; and, while a few of them buy, many others are compelled to sell to the Jews (notwithstanding the law which prohibits the purchase of land by Jews) or to German immigrants. The estates of the nobility do not pass into the hands of the Polish peasants as they are sold, and still less to Russians, but largely into those of German immigrants.

Agriculture in Poland is carried on with more perfect methods on the whole than in Russia. The extensive cultivation of beetroot, of potatoes for distilleries, and of grasses has led to the introduction of a rotation of several years instead of the former "three-fields" system; and agricultural machinery is in more general use, especially on the larger estates of the west. Winter wheat is extensively cultivated, especially in the south, the Sandomir wheat having a wide repute. In 1873 50 per cent. (15,728,000 acres) of the surface of Poland was under crops, 9 per cent. (2,929,000 acres) under meadows, and 26 per cent. (8,242,000 acres) under forests. The first of these figures exceeds now 54 per cent. In 1881 the crops reached 19,050,000 quarters [152,400,000 bu.] of corn, 21,151,000 quarters [169,208,000 bu.] of potatoes, and 14,368,000 cwts. of beetroot (14,365,950 cwts. in 1882). The corn crops were distributed as follows: wheat, 11 per cent.; rye, 38; oats, 29; barley, 12; buckwheat, 4; various, 6 per cent.,—3 per cent. being used for manufactures, 22 per cent. for seed, 60 per cent. for home consumption, and 15 per cent. for export. The potatoes were used almost entirely for distilleries. The culture of tobacco is successfully carried on (about 3500 acres), especially in Warsaw, Plock, and Lublin.

Cattle rearing is an important source of income. In 1881 there were approximately 3,300,000 cattle, 4,500,000 sheep (including 2,500,000 of the finer breeds), and 1,000,000 horses. Fine breeds of horses and cattle occur on the larger estates of the nobility, and cattle are exported to Austria. Bee-keeping is widely spread, especially in the southeast. Fishing is carried on remuneratively, especially on the Vistula and its tributaries.

Manufactures have shown a rapid increase during the last twenty years. While in 1864 the annual production was only 50,000,000 roubles, [\$38,500,000] it now exceeds 150,000,000 [\$115,500,000]—the manufactures of Poland yielding one-eighth of the total production of the Russian empire.

Mining has shown a still more rapid development within the same period. While in 1862 only 154,100 cwts. of pig iron and 100,900 cwts. of iron and steel were made, these figures respectively reached 947,800 and 1,742,500 cwts. in

1881; and, whereas the highest figure in the annual returns of the coal-mining industry from 1867 to 1873 was only 2,494,000 cwts., the average for 1876-80 was 17,157,000, and the amount reached 27,659,000 cwts. in 1881. The zinc mines yielded in 1881 89,640-cwts., and the extraction of tin reached 7,580 cwts. in 1878. Sulphur was obtained to the amount of 6450 cwts. in 1879.

The development of the leading manufactures may be seen from the following figures:

	1866.		1879.	
	Produce in Roubles.	Hands.	Produce in Roubles.	Hands.
Woollen stuffs.....	7,134,483	7,579	26,833,000	12,716
Linen and hemp stuffs.....	1,151,382	6,669	2,294,000	6,900
Cottons.....	6,099,474	9,578	22,492,000	16,949
Silks.....	61,785	100	533,000	350
Preparation, dyeing, hats.....	606,656	165	4,318,000	906
Paper wares.....	587,552	1,083	1,343,000	1,289
Produce from wood.....	311,126	379	2,665,000	2,497
Animal produce.....	4,150,756	5,579	8,572,000	3,182
Mineral produce.....	1,591,833	5,583	4,469,000	7,096
Metallic wares.....	5,654,496	7,149	9,426,000	7,599
Chemical produce.....	443,980	368	900,000	443
Total.....	27,793,523	44,232	83,845,000	60,227
Average production per hand.....	628	1,375
	[\$483.56]		[\$1058.75]	

Thus, while the number of hands occupied in these industries has increased by 40 per cent., the production has nearly trebled, showing a corresponding improvement in the machinery employed. The chief manufacturing centres are the Łódź region in the government of Piotrków (woollen stuffs, cotton, sugar, corn-flour, wine-spirit, coal-mines) and Warsaw (linen stuffs, leather, machinery, sugar, wine-spirits, tobacco, and all kinds of grocery and mercery wares). Mining is chiefly concentrated in the southwest. The annual production for separate governments (exclusive of mining, flour-mills, and breweries, and the number of hands employed by distilleries remaining unknown) was given in 1879 as follows:

	Roubles.	Hands.
Piotrków.....	60,900,000	36,550
Warsaw.....	42,110,000	37,605
Kalisz.....	14,670,000	9,159
Lublin.....	10,495,000	5,577
Łomża.....	4,543,000	581
Kielce.....	2,919,000	2,337
Radom.....	2,121,000	1,708
Plock.....	2,109,000	1,747
Siedlce.....	1,862,000	1,815
Suwałki.....	684,000	403
Total.....	142,413,000	97,482
	[\$109,658,010]	
Russia in Europe.....	1,102,949,000	711,097
	[\$849,270,730]	

These figures, however, have already increased considerably, especially with regard to distilleries, which yielded, in 1882-83, 6,269,500 gallons of pure alcohol; while the sugar-works, which occupied in 1882-83 9774 men, 2636 women, and 2403 children, produced 315,460 cwts. of rough sugar and 425,800 cwts. of refined sugar. In 1882 the production reached 66,291,700 roubles [\$51,044,609] in Piotrków, 3,948,200 [\$3,040,114] in Siedlce, and 1,240,230 [\$954,977.10] in Suwałki.

The railways of Poland have an aggregate length of 888 miles. A line of great importance, connecting Vienna with St. Petersburg, crosses the country from southwest to northeast, passing through the mining district and Warsaw, and sending a short branch to Łódź. Another important line connecting Dantzie with Odessa, crosses Poland from northwest to southeast. A branch line, parallel to this last connects Skierniewice with Thorn and Bromberg; while a military railway connects the fortresses of Warsaw and Ivangorod with Brest-Litowsky, *via* Siedlce and Łukow, and a side line

will soon connect Siedlce with Małkin on the lower Bug. The great line from Berlin to St. Petersburg crosses North Suwałki for 54 miles, between Eydtkunen and Kovno. The aggregate length of the macadamized roads, increased by 2110 miles since 1864, is now about 6700 miles.

The traffic on the Polish railways is very brisk. In 1880 the aggregate amount of merchandise brought to and sent from Warsaw reached respectively 36,055,000 and 18,248,000 cwts.; and the whole amount of merchandise conveyed on Polish railways within Poland (exclusive of the Eydtkunen and Kovno line) amounted to 81,469,000 cwts.

The chief custom-houses of the Russian empire—Wierzbolowo, Sosnowice, Granica, Warsaw—and many minor ones are situated on the frontiers of Poland. Their aggregate imports and exports reached respectively 127,414,054 [\$98,108,821.58] and 146,320,921 roubles [\$112,667,109.17] in 1882.

The "primary cell" of the administrative organization of Poland is the *gmina*,—formerly a village commune for the common possession and partly also for the common cultivation of land, which lost its characters with the introduction of serfdom, but has been taken by the law of 1864 as the basis of the organization of the peasantry in Poland. Each district is subdivided into twelve to twenty *gminas*, including several villages and all farms on its territory, and having a population of from 2000 to 10,000 inhabitants. All land-holders of the *gmina* who are in possession of at least 4 acres constitute the communal assembly of the *gmina*. Only the clergymen and the police officials are excluded from it. Each member has but one vote, however extensive his property. The *gmina* differs thus from the Russian *volost* in its including, not only peasants, but also all landed proprietors of the territory. The assembly elects the *voit*, or elder (the executive of the *gmina*), a clerk, a *sottys* in each village, and a tribunal consisting of *tawniki*, who judge all matters of minor importance, according to local customs. It also allocates the taxation among the members of the *gmina*, administers the common property (pasturage, grazing lands, forests), has charge of the poor, and generally deals with all questions educational, hygienic, and economic which concern the *gmina*. The cost of administration of each *gmina* varies from 1000 [\$770] to 3000 [\$2,310] roubles. In reality, the powers of the *gmina* are, however, very much limited in all but purely economical questions by a numerous bureaucracy, and especially by the "chief of the district" nominated by the crown; there is also a general tendency towards transforming it into a mere auxiliary to the Russian administration, the clerk or secretary becoming its chief organ.

The provincial administration is regulated by the law of December 31, 1866. Each government being subdivided into ten or twelve districts, the district administration consists of an *ouyeznyi natchalnik*, or "chief of the district," with a number of secretaries and "chancelleries" (military, for recruiting; philanthropic; for mutual assurance against fire; for finance, and for gendarmerie). The provincial administration, under a military governor, consists in each of the ten governments of the following institutions:—(1) "chancellery" of the governor; (2) a provincial "college," with councillors corresponding to the following departments—administration, military and police, finance, state domains, law, medicine, and insurance; (3) a philanthropic committee; (4) a postal department; (5) a "college" for finance; (6-10) departments of excise, customs, forests, control, and education. There is also in each government a special institution for the affairs of peasants.

The entire administration of Poland is under the governor-general, residing at Warsaw, whose power is limited only by "collegiate" institutions corresponding to the different branches of administration. He is at the same time the commander of the entire military force of the "Warsaw military district." Justice is represented by the *gmina* tribunals; the justices of the peace (nominated by government); the *syezd*, or "court" of the justices of the peace; the district tribunals (*assizes*) in each government; and the Warsaw courts of appeal and cassation. The prisons of Poland, with exception of a reformatory for boys at Studzień, are in a very bad state. With an aggregate capacity for only 4050 prisoners, they had in 1883 7210 inmates. Poland constitutes also a separate educational district, a district of roads and communications, an administration of justice district, and two mining districts.

Poland has had no separate budget since 1867; its income and expenditure are included in those of the empire, and since 1881 they have ceased to appear under separate heads. The peasants' arrears, which reached 663,685 [\$511,027.45] in 1878, have notably increased since then, ranging from 200,000 [\$154,000] to 600,000 [\$462,000] roubles in each government.

Perhaps no other country in Europe had so many towns (453), for the most part enjoying municipal rights according to the Magdeburg and Lithuanian law, as Poland. A large number of them (225) remained, however, private property or property of the crown. In some of them the proprietors only levied rents on the holders of land that had been built upon; while in others the *dominium supremum* was maintained, and the proprietor exacted, not only rents, but also taxes from the inhabitants and visitors, claiming also the monopoly of selling spirits, etc.

After the last insurrection, all towns with less than 2000 inhabitants were deprived of their municipal rights, and were included, under the designation of *posads*, in the *gminas*. The seigniorial rights were abolished or redeemed, and those inhabitants who lived on agriculture received allotments of land redeemed by the state. But the spirit-selling monopoly was maintained, as also the "servitudes." Viewed with suspicion by the Russian Government, the Polish towns received no self-government like the villages. Instead of the former elective municipal councils (which enjoyed *de jure* very large rights, including that of keeping their own police, while in reality they were under the rule of the nobility), Russian officials were nominated and entrusted with all the rights of the former municipal councils. These last were, however, maintained to carry out the orders of the military chiefs. The new municipal law of 1870, first introduced at Warsaw and then applied to other towns, reduced the functions of the municipal council almost to nothing, depriving it even of the right of discussing the general budget, which is established by a special administrative committee aided by three to four citizens nominated by the governor. The burgomaster, chosen by Government out of three candidates, and the members of the municipality (*tawniki*) elected by one section of the citizens, mostly from the poorest classes, have no authority. The burgomaster, who often is a retired private soldier, very badly paid (£18 [\$67.48] to £45 [\$218.70] per year), is entirely dependent upon the police and the chief of the district, and has to discharge all sorts of functions (bailiff, policeman, etc.) which have nothing to do with municipal affairs.

Poland naturally contains the first line of the fortifications of the Russian empire on its western frontier. These fortifications, however, are intended only to protect the country to the east of the Vistula, the region to the west of it, which contains the chief mining and manufacturing districts of Poland, remaining quite open to invasion. The marshy lowlands, covered with forests on the western bank of the Vistula, are a natural defence against an army advancing from the west, and they are supported by the fortresses on the Vistula connected by the Vistula railway. Their centre is at Warsaw, with Novogeorgievsk, formerly Modlin, in the north, at the mouth of the Bug, and Ivangorod, formerly Demblin, in the south, at the mouth of the Wieprz. Novogeorgievsk is a strongly fortified camp, which requires a garrison of 12,000 men, and may shelter an army of 50,000 men. The town Sierock, at the junction of the Bug and Narew, is now fortified to protect the rear of Novogeorgievsk.

The citadel of Warsaw protects the railway bridge over the Vistula, and six forts—rather out of date, however—protect the capital. The fortress of Ivangorod, on the right bank of the Vistula, is now supported by six forts, four of which are situated on the right bank and two on the left. The Vistula line of fortresses has, however, the great disadvantage of being easily taken from the rear by armies advancing from East Prussia or Galicia. Brest-Litowsky, at the western issue from the marshes of the Pripiet, the towns of Dubno and Lutsk, now about to be fortified, and Bobruisk constitute the second line of defence.

The educational institutions of Poland are represented by a university with 1000 students in 1881; 18 gymnasia and 8 pro-gymnasiums for boys, Education. with 8269 scholars in 1878; 3 "real-schulen," with 914 scholars; and 3279 primary schools, with 113,084 boys and 57,260 girls. There are also excellent technical schools, an institute of agriculture and forestry at Nowa-Alexandrya, and several seminaries for teachers. In 1881 the number of scholars was 1 to 35 of the aggregate population, only 19 per cent. of the children of school age receiving instruction in school. The Jewish children mostly are taught in the *heders*, where they receive almost no instruction at all.

The school is the great means used by the Russian Government for the so-called "Russification" of Poland. The teaching in the former *Szkola* "Russification. *Główna*, now the university of Warsaw (even that of Polish literature), has been carried on in Russian since 1873, both by a few Polish professors and

by the new Russian ones. Polish is taught in primary and secondary schools only twice a week, in the lower classes; and the scholars are prohibited from speaking Polish within the walls of the lyceums. In all official communications Russian is obligatory, and a gradual elimination of Poles from the administration is steadily going on, Polish employes being either limited in number (to a fourth, for instance, for the examining magistrates), or else totally excluded from certain administrations (such as that of certain railways). The vexatious measures of Russian rule keep up a continuous feeling of discontent; and, though it was allowed in 1864 that the agrarian measures would conciliate the mass of the peasantry with the Russian Government, it now appears that the peasants, while gaining in those feelings of self-respect and independence which were formerly impossible to them, are not accommodating themselves to Russian rule; the national feeling is rising into activity with them as formerly with the *szlachta*, and it grows every day.

There are 27 towns the population of which exceeded 10,000 inhabitants in 1880-82, and 66 towns having a population of more than 5000. The list of the former is as follows: Warsaw (1882), 406,260; Augustow, 11,100; Biata, 19,450; Czestochowo, 15,520; Garwolin, 14,620; Kalisz, 16,400; Kalwarya, 10,610; Kielce, 10,050; Konska Wola, 14,300; Kutno, 13,210; Łask, 10,810; Łódź, 49,590; Łomża, 15,000; Lublin, 34,980; Łukow, 11,030; Mława, 10,010; Piotrków, 23,050; Plock (1883), 19,640; Radom (1883), 19,870; Sedomierz, 14,080; Siedlce, 12,320; Sieradz, 15,040; Suwałki, 18,640; Turek, 11,500; Włocławek, 20,660; Włodawa, 17,980; Zgierz, 13,360. (P. A. K.)

POLARITY AND ENANTIOMORPHISM. Any figure, such as a solid of revolution, which has one line in it in reference to which the figure is symmetrical may be said to have an axis, and the points at which the axis cuts the surface of the figure are poles. But the term polarity when applied to material figures or substances is usually confined to cases where there are not only a definite axis and poles, but where the two poles have distinct characters which enable us to recognize them and say which is which. It is in this sense that the word is used here.

Two figures or two portions of matter are said to be *enantiomorph* to each other when these forms are not superposable, i.e., the one will not fit into a mould which fits the other, but the one is identical in form with the mirror image of the other.

Polarity.—As examples of polarity we may take an awn of barley or a cat's tail, in which we recognize the distinction between the two poles or ends, which we may call A and B by finding that it is easy to stroke from say A to B, but not in the opposite direction. As an example of enantiomorphism we may take our two hands, which will not fit the same mould or glove, but the one of which resembles in figure the mirror image of the other.

It will be seen by and by that there is a close relation between polarity and enantiomorphism.

In the examples of polarity just given the condition occurs because the parts of the body are arranged in the direction of the axis in a particular order which is different when read backwards. The simplest expression for such a state of matters will be found in the case of a substance composed of equal numbers of three different kinds of particles, these particles being arranged along the axis in the order

A | *abcabc* *abc* | B,

where A and B are poles and *a*, *b*, *c* particles of three different kinds. Of course the same may occur with a more complicated constitution, the condition being that the cyclical order read from A to B is different from that read from B to A. Even with particles all of the same kind we can imagine this sort of polarity produced by such an arrangement as

A | *aa a a a aa a a a aa a a a* | B,

where the destiny varies periodically as we pass along the axis, but so that the order of variation is different in passing from A to B and from B to A. There is another sort of polarity produced also by an arrange-

ment such as that described above, but here not along the axis but about it. As we took a cat's tail as an example of the one, so we may take a sable muff as an example of the other. As we stroke the tail in one direction along the axis, so we stroke the muff in one sense about the axis. This arrangement also produces polarity, for there is a real difference between the two ends of the muff. The one is that into which we put our right hand, the other that into which we put our left hand if the fur is to lie downwards in front. If we reverse the ends we find the fur sticking up in front, and we have thus as little difficulty in distinguishing the two poles from one another in this as in the former sort of polarity.

We can easily imagine the particles of a compound substance to be arranged so as to produce this polarity. To take a simple case—the molecules of the substance may be formed of three atoms, *a*, *b*, and *c*,

arranged *a* ^{*b*} ^{*c*} with the planes of the molecules all at right angles to the axis, so that on turning the substance about the axis in one sense the atoms in every molecule follow each other in the order *abc*, and of course in the opposite order when the rotation is reversed.

In these examples the polarity is due to an arrangement of the matter at rest, but both kinds of polarity may be produced by motion. Thus a rotating body has polarity of the second kind; the axis is the axis of rotation, and the two poles differ from each other as the two ends of a muff do. A wire along which a current of electricity is passing has polarity of the first kind; and a magnet, in which currents of electricity may be supposed to circulate about the axis, has polarity of the second kind.

There is an important difference between these two kinds of polarity. We have seen that they depend on two different conditions—the one on an arrangement of matter or motion along the axis, the other on a similar arrangement about the axis. This gives rise to a difference in their relation to their mirror image.

If we hang up a cat's tail by one end, say the A end, in front of a mirror, we see in the mirror the image of a cat's tail hanging by its A end. But if we hang up a muff by one end, say the right-hand end, before a mirror, we see in the mirror the image of a muff hanging by its left-hand end. If we put our hands into the muff in the usual way and stand before the mirror we see a person with his hands in a muff in the usual way. But his right and left hands correspond to our left and right hands respectively, and the right and left ends of the muff in the mirror are the images of the left and right ends respectively of the real muff. Thus the mirror image of a body having polarity of the second kind has its polarity reversed.

But the muff and its image are not truly enantiomorph. They differ in position but in nothing else. Turn the one round and it will fit the other.

Magnetic and electric polarity having been already discussed under **ELECTRICITY** and **MAGNETISM**, we shall here consider some cases of crystalline polarity.

Both kinds of polarity occur in crystals.

We have no direct means of ascertaining how the ultimate particles of a crystal are arranged, but it seems reasonable to suppose that there is a relation between the form of the crystal and the structure of its smallest parts; and, when we find the crystals of particular substances always showing polarity of the one or the other kind, we naturally suspect that this is the external indication of such an arrangement of the particles as has been shown above to be capable of producing structural polarity. Of crystalline polarity of the first kind the most striking instances are tourmaline and electric calamine (hydrated silicate of zinc), forms of which are shown in Figs. 1 and 2,

in which it will be seen that the crystals are not similarly terminated at the two ends. It is this kind of crystalline polarity (often called "hemimorphism") which (as was first observed by Haiiy and more fully investigated by Gustav Rose and by Hankel) is associated with pyroelectricity (see MINERALOGY, vol. xvi. p. 391). It is worthy of note that the crystalline

FIG. 1.—Tourmaline.

FIG. 2.—Electric Calamine.

polarity and the physical (electric) polarity occurring in the same substances are both of the kind not inverted by reflection in a mirror.

As an instance of the same kind of crystalline polarity of a somewhat more complicated character, also associated with pyroelectricity, we may take boracite. The crystals of this mineral exhibit combinations of the cube, the rhombic dodecahedron, and the tetrahedron, as shown in Fig. 3. If four lines are drawn corresponding to the four diagonals of the cube, it will be observed that at the two ends of each of these axes the crystal is differently developed. (In the figure one of these axes is indicated by the dotted line.) These axes, therefore, resemble the single axis in tourmaline and electric calamine, and are also axes of pyroelectricity, the end at which the tetrahedral face is situated being the antilongous pole.¹

FIG. 3.—Boracite.

Scheelite, apatite, ilmenite, and fergusonite are ex-

FIG. 4.—Ilmenite.

FIG. 5.—Apatite.

amples of crystalline polarity of the second kind. Figs. 4, 5, and 6 are representations of forms of ilmenite, apatite, and fergusonite.

Crystalline polarity of both kinds, no doubt, depends on the arrangement of the molecules and on their structure; it manifests itself by the occurrence of hemihedral or hemimorphic forms. A crystal may have a polar structure although these external marks of polarity are absent, just as the faces parallel to planes of cleavage do not appear on every crystal.

Another kind of contrast between the two complementary

FIG. 6.—Fergusonite.

hemihedral forms of the same substance may be mentioned here. Marbach observed that different specimens of iron pyrites (and also of cobalt glance) have very different thermoelectric characters, differing indeed from one another more than bismuth and antimony. Gustav Rose showed that these thermoelectrically opposite kinds are also crystallographically opposite. There is indeed no geometrical difference between two opposite hemihedral forms in the regular system, but Rose detected a difference in the lustre and striation of the faces of the two kinds, and by examining the rare cases in which the two opposite pentagonal dodecahedra or tetragonal icositetrahedra occur on the same crystal proved that the one surface character belongs to the one, the other surface character to the other of the two complementary hemihedra.

Enantiomorphism.—A figure having polarity of the first kind gives a mirror image resembling itself in form and in position; a figure having polarity of the second kind gives a mirror image resembling itself in form but not in position—the poles being inverted. A figure the axis of which has both kinds of polarity will therefore give a mirror image not superposable to the figure itself, because the polarity of the second kind is reversed while that of the first kind remains unchanged. The figure and its mirror image are enantiomorph, as well as polar.

FIG. 7.

FIG. 8.

We can construct a figure which is enantiomorph to its mirror image but not polar. Imagine a muff so made that in one half the fur lies the one way, and the opposite way in the other half (Fig. 7, where the arrow-heads indicate the lie of fur). In whichever way we put our hands into this muff one end will be wrong; the muff in the figure has, in fact, two right-hand ends. It has therefore no polarity; the two ends are exactly alike. But there are two ways in which such a non-polar muff could be made—with two right-hand ends as in the figure, or with two left-hand ends, and these two forms are enantiomorph. A helix or screw has similar properties (compare Fig. 8 with Fig. 7); if uniform it is non-polar, but is either right- or left-handed. Hence the property which each of two enantiomorph bodies possesses has been called by Sir William Thomson "helical asymmetry."

As we have crystals exhibiting polarity of both kinds, so we have also enantiomorph crystals; indeed, the word enantiomorph was first used by Naumann to express the relation between such crystals. The crystallographic theory of enantiomorph crystals has been very fully worked out. We may divide them into two groups—(1) those in which the helical asymmetry depends on the presence of tetrahedral forms of the regular or of the hexagonal system, and (2) those in which it depends on the presence of hemihedral forms of the rhombic system or hemimorphic forms of the monoclinic system.

In the first group the asymmetry seems to be produced by the manner in which the molecules, themselves symmetrical, are arranged in the crystal. In the second group the molecules themselves appear to have helical asymmetry. This is shown by the action of these substances on polarized light. We shall take examples from each group. If we allow a solution of sodium chlorate to crystallize, we find that the crystals, which belong to the regular system, are of two kinds, enantiomorph to each other. These are

¹ Upon some crystals of boracite the faces of both tetrahedra occur. They can, however, be easily distinguished from one another. The faces of the tetrahedron represented in the figure are smooth and shining, while those of the opposite tetrahedron are rough and usually much smaller. It has been suggested that boracite is only apparently regular, and that each crystal is really

a group of eight pyramids with their apices in the centre of the group. For a full discussion of the relation between pyroelectricity and crystalline form the reader is referred to a series of papers by Prof. Hankel in *Trans. R. Soc. of Sciences*, 1857-79.

represented in Fig. 9. The enantiomorphism depends on the combination of the tetrahedron and the pentagonal dodecahedron.¹ Now when a ray of plane polarized light is passed through one of these crystals the plane of polarization is rotated, the amount of rotation being proportional to the length of the path in

FIG. 9.—Sodium Chlorate. *a*, right-handed; *b*, left-handed.

the crystal. The crystals having the form *a* rotate to the right, those having the form *b* to the left. They are therefore optically as well as crystallographically enantiomorph. But a solution of sodium chlorate is without action on the plane of polarization, even if the solution be made by dissolving only right-handed or only left-handed crystals, and if a crystal be fused the fused mass is optically inactive, so that it would seem that the optical activity depends on the arrangement of the molecules in the crystal, and not on any enantiomorphism in the molecules. The enantiomorphism of quartz crystals is indicated by the presence of faces of a tetartohedral form (vol. xvi. p. 404). The two kinds of crystals rotate the plane of polarization equally, but in opposite senses, when a plane polarized ray is passed through a section cut at right angles to the axis of the crystal. Here also the optical activity ceases when crystalline structure is destroyed by fusion or solution.

Right-handed and left-handed tartaric acids crystallize in enantiomorph forms (Fig. 10). Their solutions

FIG. 10.—Tartaric Acid. *a*, right-handed; *b*, left-handed.

are optically active, the amount of the rotation for the same strength of solution and the same length of path in it being the same in both acids, but the sense of the rotation is right-handed in the one and left-handed in the other. It is clear that here we have to do with enantiomorph molecules. In ordinary physical properties such as density, solubility, refracting power—in short, in everything *not involving right- or left-handedness*—the acids are identical. When mixed in equal proportions they unite and form racemic acid which is optically inactive, and from racemic acid we can by various means recover unchanged the right and left-handed tartaric acids. We now know a considerable number of cases where, as in that of the two tartaric acids, both enantiomorphs have been discovered, and many where only one has as yet been found.

It is natural that we should ask what peculiarity of constitution can give a molecule this helicoidal asymmetry? A very ingenious answer to this question was given simultaneously and independently by the French chemist Le Bel and the Dutch chemist Van't Hoff. We shall give a short statement of the essential points of this interesting theory.

¹ This combination is regarded as tetartohedral, because the tetrahedron and the pentagonal dodecahedron belong to two different classes of hemihedral forms.

All the known substances which are optically active in solution are compounds of carbon, and may be regarded as derived from marsh gas, a compound of one atom of carbon and four of hydrogen, by the replacement of hydrogen by other elements or compound radicals. Now we do not know how the atoms of hydrogen are actually arranged relatively to each other and to the atom of carbon in the molecule of marsh gas, but, if we may make a supposition on the subject, the most simple is to imagine the four hydrogen atoms at the apices of a regular tetrahedron in the centre of which is the carbon atom as in the diagrams (Fig. 11),

FIG. 11.

where *C* represents the position of the carbon atom and *a*, *b*, *γ*, *δ* that of the four atoms of hydrogen.

If these hydrogen atoms are replaced by atoms of other elements or by compound radicals we should expect a change of form of the tetrahedron. If two or more of the atoms or radicals united to the carbon atom are similar there is only one way of arranging them, but if they are all different there are two ways in which they may be arranged, as indicated in the figures. It will be seen that these two arrangements are enantiomorph. In the figures the tetrahedron is represented as regular, but if the distance from *C* depends on the nature of the atom, the tetrahedron, when *a*, *b*, *γ*, and *δ* are all different, will not be symmetrical, but its two forms will be enantiomorph. A carbon atom combined with four different atoms or compound radicals may therefore be called an asymmetric carbon atom.

Now all substances of ascertained constitution, the solutions of which are optically active, contain an asymmetric carbon atom, and their molecules should therefore, on the above hypothesis, have helicoidal asymmetry.

The converse is not generally true. Many substances contain an asymmetric carbon atom but are optically inactive. It is easy to reconcile this with the theory; indeed, a little consideration will show that it is a necessary consequence of it.

Let us suppose that we have the symmetrical combination of *C* with *a*, *b*, *γ* and that we treat the substance in such a way that one *a* is replaced by *δ*. The new arrangement is asymmetrical, and will be right or left as the one or the other *a* is replaced. But the chances for the two are equal, and therefore, as the number of molecules in any quantity we can deal with is very great, the ratio of the number of right-handed molecules in the new substance to the number of left-handed ones will be sensibly that of unity. It is therefore evident that by ordinary chemical processes we cannot expect to produce optically active from optically inactive substances; all that we can get is an inactive mixture of equal quantities of the two oppositely active substances.

As these two substances have identical properties in every respect where right- or left-handedness is not involved, the problem of separating them is a difficult one. We may note three distinct ways in which the separation can be effected.

(1) By crystallization. For example, the right and left double tartrates of soda and ammonia crystallize in enantiomorph forms (Fig. 12) and are less soluble in water than the double racemate formed by their union. If therefore racemic acid (the optically inactive compound of equal quantities of right and left tartaric acids) is half neutralized with soda and half with ammonia, we obtain an optically inactive solution con-

taining a mixture of the two double salts. If this solution is allowed to crystallize each salt crystallizes independently, and the crystals can be separated by picking them out. Further, a supersaturated solution of the one double salt is not made to crystallize by

FIG. 12.—Double Tartrate of Soda and Ammonia. *a*, right-handed; *b*, left-handed.

contact with a crystal of the other, so that if we make a supersaturated solution of the inactive mixture and drop into the vessel, at different places, two crystals one of the right the other of the left salt, crystallization occurs at each place, at the one of the one kind and at the other of the other.

(2) By the action of another optically active substance. While the salts of the two opposite tartaric acids with an inactive base are precisely alike in solubility, density and other physical characters, and, if they crystallize, crystallize in the same form (or in enantiomorph forms), it is not at all so when the base is optically active; thus right tartaric acid forms a crystalline salt with left asparagine, while with the same base left tartaric acid gives an uncrystallizable compound.

(3) By the action of living ferments. The minute fungi which act as ferments do not show any right- or left-handedness as far as their obvious anatomical structure is concerned, but Pasteur has shown that some of them are, if we may use the expression, physiologically asymmetrical. As an example we may give the very interesting case of mandelic acid. This acid, which stands to benzoic aldehyde (bitter almond oil) in the same relation as lactic acid does to common aldehyde, contains one asymmetric carbon atom in its molecule. It is optically inactive, and therefore, if Le Bel and Van 't Hoff's theory is true, it must be a mixture of two oppositely active acids. Now Lewkowitzsch found that when *Penicillium glaucum* is cultivated in a solution of mandelic acid fermentation takes

place. This goes on until exactly half of the acid is decomposed, and what remains has all the properties of mandelic acid, but is optically active; it is the right-handed component of the mixture, the growing fungus having consumed the other.

There is an interesting peculiarity of tartaric acid discovered by Pasteur (to whom we owe nearly all our knowledge of the relations between optical activity and crystalline form in tartaric acid) which is of importance in connection with the theory we have just been explaining.

We have not only right and left tartaric acid and racemic acid, the inactive compound of the two, but also a kind of tartaric acid which is inactive, but incapable of being separated into the two oppositely active acids.

Now the chemical formula of tartaric acid is

It will be observed that the carbon atoms marked * are asymmetric, and that they occupy precisely similar positions in the molecule. Each of them is combined with H, OH, COOH and CH(OH)COOH. If in both of them these four things are arranged in the same order there is helicoidal asymmetry—the one order giving the one, the other the other enantiomorph form. But if the one has one order and the other the opposite, then there is in the whole molecule no helicoidal asymmetry, as the two halves exactly balance one another. There is not, as in racemic acid, a compound of one molecule of each of the two opposite active acids, but rather a compound of half a molecule of each, and we should not expect such a compound to be easily separable. Jungfleisch has shown that if any one of the four tartaric acids (right, left, racemic and inactive) is mixed with a little water and kept for some time at a temperature of about 200° C., it is converted into a mixture of racemic and inactive tartaric acids, so that, as racemic acid can be divided into right and left tartaric acids, it is possible to prepare any one of the four from any other. (A. C. B.)

POLARIZATION OF LIGHT. See LIGHT AND WAVE THEORY.

POLAR REGIONS.

THE polar regions extend respectively from the Arctic and Antarctic Circles, in 66° 32' N. and S. to the north and south poles, the circles being 1,408 geographical miles from the poles. The intense cold and the difficulties of ice navigation have made the discovery and examination of these regions a slow and hazardous task. Millions of square miles are still entirely unknown. In the present article the history of the progress of discovery within the north polar region will be traced and some account of its physical geography will follow. A similar review of work in the south polar region will conclude the article.

NORTH POLAR REGION.

The Arctic Circle is a ring running a little south of the northern shores of America, Asia and Europe, so that those shores form a fringe within the polar region and are its boundary to the south, except at three openings—those of the North Atlantic, of Davis Strait and of Behring's (more properly Bering's) Strait.

The width of the approach to this region by the Atlantic Ocean, in its narrowest part, is 660 miles, from the Norwegian islands of Lofö-Approaches, ten to Cape Hodgson on the east coast of Greenland. The width of the approach by Davis Strait in the narrowest part, which is nearly on the Arctic Circle, is 165 miles, and the width of Behring's Strait is 45 miles. Thus out of the whole ring of 8,640 miles along which the Arctic Circle passes about 900 miles is over water. This great environment of land is an important feature in the physical condition of the north polar region. It influences the currents and the movements of ice, which are still further affected by the archipelagoes lying to the northward of the fringing coast-lines. The larger opening into the north polar region by way of the Atlantic is divided from Davis Strait by the vast mass of Greenland, which, extending for an unknown distance to the north, crosses the Arctic Circle and ends in a point at Cape Farewell in 59° 48' N. lat. It was inevitable that the routes across the Arctic Circle by the Atlantic and Davis Strait should first become known, because these openings to the polar regions are nearest to the tem-

perate regions inhabited by the exploring nations of Europe.

A rumor respecting Thule, an island on the Arctic Circle, first brought by PYTHEAS (*q.v.*), and afterwards doubted, was the extent of the knowledge of the north polar regions with which the ancients can be credited. But in the 9th century some Irish monks really appear to have visited Iceland. The monk Dicuil, writing about 825, says that he had information from brethren who had been at Thule during several months and they reported that there was no darkness at the summer solstice.

King Alfred told the story of the first polar voyages undertaken for discovery and the acquisition of knowledge, in his very free translation of Orosius. In the first book he inserted the narrative of the voyages of Other and Wulfstan, related to him by the former explorer himself. The localities mentioned in the story cannot now be identified, but it seems probable that Other rounded the North Cape, and visited the coast of Lapland.

The Norsemen of the Scandinavian peninsula, after colonizing Iceland, were the first to make permanent settlements on the shores of Greenland, and to extend their voyages beyond the Arctic circle along the western coast of that vast glacier-covered land. See GREENLAND. The Norse colonies in Greenland at Brattelid and Einarsfjord did not extend farther north than 65°, but in the summer time the settlers carried on their seal hunting far beyond the Arctic circle. One of their runic stones was found in a cairn in latitude 73° N., the inscription showing that the date of its being left there was 1235. Another expedition is believed, on good grounds, to have reached a latitude of 75° 46' N. in Barrow Strait, about the year 1266. Their ordinary hunting grounds were in 73° N., to the north of the modern Danish settlement of Upernivik. For the visits of the Greenlanders to the American coasts see AMERICA, vol. i. p. 620.

The last trace of communication between Greenland and Norway was in 1347. The black death broke out in Norway and the far off colony was forgotten; while the settlers were attacked by Skrellings or Eskimo, who overran the West Bygd in 1349. Ivar Bardsen, the steward to the bishopric of Gardar in the East Bygd, and a native of Greenland, was sent to convey help to the sister colony. A document, of which Ivar Bardsen was the author, has been preserved. It consists of sailing directions for reaching the colony from Iceland, and a chorography of the colony itself. It is the oldest work on arctic geography, and is still valuable in the study of all questions relating to the early settlements in Greenland. From 1400 to 1448 there was some communication, at long intervals, with the Greenland settlers, but during the latter half of that century it entirely ceased. Here then the ancient portion of polar history comes to an end. The next period, comprised in the 16th and 17th centuries, was that in which expeditions were despatched across the Arctic Circle to discover a shorter route to India.

Sebastian Cabot, whose own northern voyages have been spoken of in the article CABOT, was the chief promoter of the expedition which sailed under Sir Hugh Willoughby and Richard Chancellor on the 20th May, 1553, "for the search and discovery of the northern parts of the world, to open a way and passage to our men, for travel to new and unknown kingdoms." Willoughby, after discovering Nova Zembla (Novaya Zemlya) by sighting the coast of Goose Land, resolved to winter in a harbor of Lapland, where he and all his men perished of starvation and cold. Chancellor reached the Bay of Archangel. St. Nicholas, and landed near Archangel, which was then only a castle. He undertook a journey to Moscow, made arrangements for commercial intercourse with Russia, and returned safely. His success proved the practical utility of polar voyages. It led to

a charter being granted to the association of Merchant Adventurers, of which Cabot was named governor for life, and gave fresh impulse to arctic discovery.

In the spring of 1556 Stephen Burrough, who had served with Chancellor, sailed in a small pin-nace called the "Searchthrift," and kept a careful journal of his voyage. He went to Archangel, and discovered the strait leading into the Kara sea, between Nova Zembla and the island of Waigat. In May, 1580, the company fitted out two vessels under Arthur Pet and Charles Jackman, with orders to pass through the strait discovered by Burrough, and thence to sail eastward beyond the mouth of the river Obi. Pet discovered the strait into the Kara Sea, between Waigat and the mainland, and made a persevering effort to push eastward, returning to England in safety. Jackman, after wintering in a Norwegian port, sailed homeward but was never heard of again.

In 1558 a narrative and map were published at Venice which profoundly affected the system of polar cartography for many years afterwards. The publication was the handiwork of a Venetian nobleman named Niccolò Zeno. Towards the close of the 14th century his ancestor, also named Niccolò, made a voyage into the northern seas, and entered the service of a chief named Zichnmi as pilot. He was eventually joined by his brother Antonio, and four years afterwards died in the country he called Frislanda. Antonio remained ten years longer in the service of Zichnmi, and then returned to Venice. The younger Niccolò found the mutilated letters of these brothers in the Zeni palace, with a map; and out of these materials he prepared the narrative and map which he published, adding what he considered improvements to the map. It was accepted at the time as a work of high authority, and the names on it continued to appear on subsequent maps for at least a century, puzzling both geographers at home and explorers in the field. After a very exhaustive study of the subject, Mr. Major has identified the names on the Zeni map as follows: Engroneland, Greenland; Islanda, Iceland; Estland, Shetlands; Frisland, Faroe Isles; Markland, Nova Scotia; Estotiland, Newfoundland; Drogeo, coast of North America; Icaria, coast of Kerry in Ireland.

We now come to the voyages of Frobisher, undertaken to obtain the means for equipping an expedition for the discovery of a shorter route to India by the northwest. Aided by Michael Lok, an influential merchant and diligent student of geography, Frobisher sailed, in the spring of 1576, with two small vessels of 20 to 25 tons, called the "Gabriel" and "Michael." But the "Michael" parted company in the Atlantic, the voyage being continued in the "Gabriel" alone. On 20th July, Frobisher sighted high land, which he called Queen Elizabeth's Foreland; and the next day he entered the strait to which he gave his own name, calling the land "Meta Incognita." On his return in the autumn, with various specimens of plants and stones, the "goldfinders" in London took it into their heads that a glittering piece of mica-schist contained gold ore. This caused great excitement, and much larger expeditions were fitted out, in the two following years, to collect these precious ores. As many as fifteen vessels formed the third expedition of 1578, and one of them, a busse (small ship) of Bridgwater, called the "Emma," reported that on her voyage home she had sighted land in the Atlantic and sailed along it for three days. It was never seen again, and may have been only a large ice-field; but it soon found its place on maps and charts under the name of Busse Island, and afterwards as "sunken land of Busse." For a long time Frobisher Strait was supposed to pass through Greenland, and, the map of the Zeni adding to the confusion, the

¹ Admiral Irminger of Copenhagen holds the opinion that Frisland is not the Faroe Isles, but Iceland.

land to the south was called Frislanda. It is now clear that Frobisher never saw Greenland, and that his strait and "Meta Incognita" are on the American side of Davis Strait. What Frobisher really did was to establish the fact that there were two or more wide openings leading to the westward, between latitudes 60° and 63°, on the American coast.

John Davis, who made the next attempt to discover a northwest passage, was one of the most scientific seamen of that age. He made three voyages in three successive years, aided and fitted out by William Sanderson and other merchants.

Sailing from Dartmouth on the 7th June, 1585, he was the first to visit the west coast of Greenland subsequent to the abandonment of the Norse colonies. He called it "The Land of Desolation." He discovered Gilbert's Sound in 64° 10' (where now stands the Danish settlement of Godthaab), and then, crossing the strait which bears his name, he traced a portion of its western shore. In the second voyage Davis noted what he calls "a furious overfall," which was the tide flowing into Hudson Strait; and in his third voyage, in 1587, he advanced far up his own strait, and reached a lofty granite island in 72° 41' N., which he named Sanderson's Hope. He considered that there was good hope of advancing farther, and reported "no ice towards the north, but a great sea, free, large, very salt and blue, and of an unsearchable depth." The results of his discoveries are shown on the Molyneux globe which is now in the library of the Middle Temple; but he found it impossible to reconcile his work with that of Frobisher, and with the Zeni map. In 1595 Davis published a tract entitled *The World's Hydrographical Description*, in which he ably states the arguments in favor of the discovery of a northwest passage.

The Dutch also saw the importance of a northern route to China and India, especially as the routes by the Cape of Good Hope and Magellan's Strait were jealously guarded by Spaniards and Portuguese. Their plan was to proceed by the northeast along the coast of Asia. As early as 1578 Dutch merchants had opened a trade with Kola and Archangel, but it was Peter Plancius, the learned cosmographer of Amsterdam, who conceived the idea of discovering a northeast passage. In 1594 the Amsterdam merchants fitted out a vessel of 100 tons, under the command of Willem Barents. The coast of Nova Zembla was sighted on the 4th July, and from that date until the 3d of August Barents continued perseveringly to seek a way through the ice-floes, and discovered the whole western coast as far as Cape Nassau and the Orange Islands at the northwest extremity. The second voyage in which Barents was engaged merely made an unsuccessful attempt to enter the Kara Sea. The third was more important. Two vessels sailed from Amsterdam on May 13, 1596, under the command of Jacob van Heemskerck and Corneliszoon Rijp. Barents accompanied Heemskerck as pilot, and Gerrit de Veer, the historian of the voyage, was on board as mate. The masses of ice in the straits leading to the Sea of Kara, and the impenetrable nature of the pack near Nova Zembla, had suggested the advisability of avoiding the land, and, by keeping a northerly course, of seeking a passage in the open sea. They sailed northwards, and on 9th June discovered Bear Island. Continuing on the same course they sighted the northwestern extreme of Spitzbergen, soon afterwards being stopped by the polar pack ice. This important discovery was named "Nieuwe Land," and was believed to be a part of Greenland. Arriving at Bear Island again on 1st July, Rijp parted company, while Heemskerck and Barents proceeded eastward, intending to pass round the northern extreme of Nova Zembla. On the 26th August they reached Ice Haven, after rounding the northern extremity of the land. Here they wintered in a house built out of driftwood

and planks from the wrecked vessel. In the spring they made their way in boats to the Lapland coast; but Barents died during the voyage. This was the first time that an arctic winter was successfully faced. The voyages of Barents stand in the first rank among the polar enterprises of the 16th century. They led directly to the flourishing whale and seal fisheries which long enriched the Netherlands.

The English enterprises were continued by the Muscovy Company, and by associations of patriotic merchants of London; and even the East India Company sent an expedition under Captain Waymouth in 1602 to seek for a passage by the opening seen by Davis, but it had no success.

The best servant of the Muscovy Company in the work of Polar discovery was Henry Hudson.

Hudson. His first voyage was undertaken in 1607, when he discovered the most northern known point of the east coast of Greenland in 73° N. named "Hold with Hope," and examined the edge of the ice between Greenland and Spitzbergen, reaching a latitude of 80° 23' N. On his way home he discovered the island now called Jan Mayen, which he named "Hudson's Tutches." In his second expedition, during the season of 1608, Hudson examined the edge of the ice between Spitzbergen and Nova Zembla. In his third voyage he was employed by the Dutch East India Company, and he explored the coasts of North America, discovering the Hudson river. In 1610 he discovered Hudson's Strait, and the great bay which bears and immortalizes his name (see HUDSON, vol. xii. p. 346).

The voyages of Hudson led immediately to the Spitzbergen whale fishery. From 1609 to 1612 Jonas Poole made four voyages for the prosecution of this lucrative business, and he was followed by Fotherby, Baffin, Joseph and Edge. These bold seamen, while in the pursuit of whales, added considerably to the knowledge of the archipelago of islands known under the name of Spitzbergen, and in 1617 Captain Edge discovered a large island to the eastward, which he named Wyche's Land.

At about the same period the kings of Denmark began to send expeditions for the rediscovery of the lost Greenland colony. In 1605 Christian IV. sent out three ships, under the Englishmen Cunningham and Hall, and a Dane named Lindenov, which reached the western coast of Greenland and had much intercourse with the Eskimo. Other expeditions followed in 1606-7.

Meanwhile the merchant adventurers of London continued to push forward the western discovery. Sir Thomas Button, in command of two ships, the "Resolution" and "Discovery," sailed from England in May, 1612. He entered Hudson's Bay, crossed to its western shore, and wintered at the mouth of a river in 57° 10' N. which was named Nelson's river after the master of the ship, who died and was buried there. Next year Button explored the shore of Southampton Island as far as 65° N., and returned home in the autumn of 1613. An expedition under Captain Gibbons, despatched in 1614, was a miserable failure; but in 1615 Robert Bylot as master and William Baffin as pilot and navigator in the "Discovery" examined the coasts of Hudson's Strait, and Baffin, who was the equal of Davis as a scientific seaman, made many valuable observations. In 1616 Bylot and Baffin again set out in the "Discovery." Sailing up Davis Strait they passed that navigator's farthest point at Sanderson's Hope, and sailed round the great channel with smaller channels leading from it which has been known ever since as Baffin's Bay. Baffin named the most northern opening Smith Sound, after the first governor of the East India Company, and the munificent promoter of the voyage, Sir Thomas Smith. Wolsten-

Waymouth.

Spitzbergen whale fishery.

Danish voyages.

Button.

Baffin.

holme Sound, Cape Dudley Digges, Hakluyt Island, Lancaster Sound, Jones Sound, and the Cary Islands were named after other promoters and friends of the voyage. The fame of Baffin mainly rests upon the discovery of the great channel extending north from Davis Strait; but it was unjustly dimmed for many years, owing to the omission of Purchas to publish the skilful navigator's tabulated journal and map in his great collection of voyages. It may be mentioned, as an illustration of the value of these early voyages to modern science, that Professor Hansteen of Christiania made use of Baffin's magnetic observations in the compilation of his series of magnetic maps.

In 1631 two expeditions were despatched, one by the merchants of London, the others by those of Bristol. In the London ship "Charles" Luke Fox explored the western side of Hudson's Bay as far as the place called "Sir Thomas Roe's Welcome." In August he encountered Captain James. James and the Bristol ship "Maria" in the middle of Hudson's Bay, and went north until he reached "Northwest Fox his furthest," in 66° 47' N. He then returned home and wrote the most entertaining of all the Polar narratives. Captain James was obliged to winter off Charlton Island, in the southern extreme of Baffin's Bay, and did not return until October, 1632. Another English voyager, Captain Wood, attempted, without success, to discover a northeast passage in 1676.

The 16th and 17th centuries were periods of discovery and daring enterprise, and the results gained by the gallant seamen of those times are marvellous when we consider their insignificant resources and the small size of their vessels. Hudson's Strait and Bay, Davis Strait, and Baffin's Bay, the icy seas from Greenland to Spitzbergen and from Spitzbergen to Nova Zembla, had all been discovered. The following century was rather a period of reaping the results of former efforts than of discovery. It saw the settlement of the Hudson's Bay Territory and of Greenland, and the development of the whale and seal fisheries.

The Hudson's Bay Company was incorporated in 1670, and Prince Rupert sent out Zachariah Gillan, who wintered at Rupert's river. At first very slow progress was made. A voyage undertaken by Mr. Knight, who had been appointed governor of the factory at Nelson river, was unfortunate, as his two ships were lost and the crews perished. This was in 1719.

In 1722 John Scrooges was sent from Seroggs. Churchill river in search of the missing ships, but merely entered Sir Thomas Roe's Welcome and returned. His reports were believed to offer decisive proofs of the existence of a passage into the Pacific; and a naval expedition was despatched under the command of Captain Christopher Middleton, consisting of the "Discovery" pink and the "Furnace" bomb. Wintering in Churchill river, Middleton started in July, 1742 and discovered Wager river and Repulse Bay. In 1746 Captain W. Moor made another voyage in the same direction, and explored the Wager Inlet.

Captain Coats, who was in the service of the company 1727-51, wrote a useful account of the geography of Hudson's Bay. Later in the century the Hudson's Bay Company's servants made some important land journeys to discover the shores of the American polar ocean. From 1769 to 1772 Samuel Hearne descended the Coppermine river to the polar sea; and in 1789 Alexander Mackenzie discovered the mouth of the Mackenzie river.

The establishment of the modern Danish settlements in Greenland has already been spoken of under the heading GREENLAND (*q.v.*). The countrymen of Barents vied with the countrymen of Hudson in the perilous calling which annually brought fleets of ships to the Spitzbergen seas during the 18th century.

The Dutch had their large summer station for boiling down blubber at Smeerenberg, near the northern extreme of the west coast of Spitzbergen. Captain Vlammingh, in 1664, advanced as far round the northern end of Nova Zembla as the winter quarters of Barents. In 1700 Captain Cornelis Roule is said by Witsen to have sailed north in the longitude of Nova Zembla, and to have seen an extent of 40 miles of broken land. But Theunis Ys, one of the most experienced Dutch navigators, was of opinion that no vessel had ever been north of the 82d parallel. In 1671 Frederick Martens visited the Spitzbergen group, and wrote the best account of its physical features and natural history that existed previous to the time of Scoresby. In 1707 Captain Gilies and Outsger Rep went far to the eastward along the northern shores of Greenland, and saw very high land in 80° N., which has since been known as Gilies Land. The Dutch geographical knowledge of Spitzbergen was embodied in the famous chart of the Van Keulens (father and son), 1700-1728. The Dutch whale fishery continued to flourish until the French Revolution, and formed a splendid nursery for training the seamen of the Netherlands. From 1700 to 1775 the fleet numbered 100 ships and upwards. In 1719 the Dutch opened a whale fishery in Davis Strait, and continued to frequent the west coast of Greenland for upwards of sixty years from that time. In the course of 6372 Dutch whaling voyages to Davis Strait between 1719 and 1775 only 38 ships were wrecked.

The most flourishing period of the English fishery in the Spitzbergen seas was from 1752 to 1820. Bounties of 40s. per ton were granted by Act of Parliament; and in 1778 as many as 255 sail of whalers were employed. In order to encourage discovery £5000 were offered in 1776 to the first ship that should sail beyond the 89th parallel (16 *Geo.* III. c. 6). Among the numerous daring and able whaling captains, Captain Scoresby takes the first rank, alike as a successful fisher and a scientific observer. His admirable *Account of the Arctic Regions* is still a text book for all students of the subject. In 1806 he succeeded in advancing his ship "Resolution" as far north as 81° 12' 42". In 1822 he forced his way through the ice which encumbers the approach to land on the east coast of Greenland, and surveyed that coast from 75° down to 69° N., a distance of 400 miles. Scoresby combined the closest attention to his business with much valuable scientific work and no insignificant amount of exploration.

The Russians, after the acquisition of Siberia, succeeded in gradually exploring the whole of the northern shores of that vast region. As long ago as 1648 a Cossack named Simon Deshneff equipped a boat expedition in the river Kolyma, passed through the strait afterwards named after Bering, and reached the Gulf of Anadyr. In 1738¹ a voyage was made by two Russian officers from Archangel to the mouths of the Obi and Yenisei. Efforts were then made to effect a passage from the Yenisei to the Lena. In 1735 Lieutenant T. Tchelyuskin got as far as 77° 25' N. near the cape which bears his name; and in 1743 he reached that most northern point of Siberia in sledges, in 77° 41' N. Captain Vitus Bering, a Dane, was appointed by Peter the Great to command an expedition in 1725. Two vessels were built at Okhotsk, and in July, 1728, Bering ascertained the existence of a strait between Asia and America. In 1740 Bering was again employed. He sailed from Okhotsk in a vessel called the "St. Paul," with G. W. Steller on board as naturalist. Their object was to discover the American side of the strait, and they

sighted that magnificent peak named by Bering Mount St. Elias. The Aleutian Islands were also explored, but the ship was wrecked on an island named after the ill-fated discoverer, and scurvy broke out amongst his crew. Bering himself died there on December 8, 1741.

Thirty years after the death of Bering a Russian merchant named Liakhoff discovered the New Siberia or Liakhoff Islands, and in 1771 he obtained the exclusive right from the empress Catherine to dig there for fossil ivory. These islands were more fully explored by an officer Hedenström, named Hedenström in 1809, and seekers for fossil ivory annually resorted to them. A Russian expedition under Captain Tchitschakoff, sent to Spitzbergen in 1764, was only able to attain a latitude of 80° 30' N.

Since the year 1773 the objects of polar exploration, at least so far as England is concerned, have been mainly the acquisition of knowledge in various branches of science. It was on these grounds that the Honorable Daines Barrington and the Royal Society induced the Government to undertake arctic exploration once more. The result was that two vessels, the "Racehorse" and "Carcass" bombs, were commissioned, under the command of Captain Phipps.

The expedition sailed from the Nore on the 2d June, 1773, and was stopped by the ice to the north of Hakluyt Headland, the northwestern point of Spitzbergen. They reached the Seven Islands and discovered Walden Island; but beyond this point progress was impossible. When they attained their highest latitude in 80° 48' N., north of the central part of the Spitzbergen group, the ice at the edge of the pack was 24 feet thick. Captain Phipps returned to England in September, 1773. Five years afterwards

Captain Cook received instructions to proceed northward from Kamchatka and search for a northeast or northwest passage from the Pacific to the Atlantic. In accordance with these orders Captain Cook, during his third voyage, reached Cape Prince of Wales, the western extremity of America, on August 9, 1778. His ships, the "Resolution" and "Discovery," arrived at the edge of the ice, after passing Behring Strait, in 70° 41' N. On August 17th the farthest point seen on the American side was named Icy Cape. On the Asiatic side Cook's survey extended to Cape North. In the following year Captain Clerke, who had succeeded to the command, made another attempt, but his ship was beset in the ice, and so much damaged that further attempts were abandoned.

The wars following the French Revolution put an end to voyages of discovery till, after the peace of 1815, north polar research found a powerful and indefatigable advocate in Sir John BARROW (*q.v.*). Through his influence a measure for promoting polar discovery became law in 1818 (58 Geo. III. c. 20), by which a reward of £20,000 was offered for making the northwest passage, and of £5000 for reaching 89° N., while the commissioners of longitude were empowered to award proportionate sums to those who might achieve certain portions of such discoveries. In 1817 the icy seas were reported by Captain Scoresby and others to be remarkably open, and this circumstance enabled Barrow to obtain sanction for the dispatch of two expeditions, each consisting of two whalers—one to attempt discoveries by way of Spitzbergen and the other by Baffin's Bay. The vessels for the Spitzbergen route, the "Dorothea" and "Trent," were commanded by Captain David Buchan and Lieutenant John Franklin, and sailed in April, 1818. Driven into the pack by a heavy swell from the south, both vessels were severely nipped, and had to return to England. The other expedition, consisting of the "Isabella" and "Alexander," commanded by Captain John Ross and Lieutenant Edward Parry, followed in the wake of Baffin's voyage of 1616. Ross sailed from England in April, 1818. The chief merit of his voyage was that

it vindicated Baffin's accuracy as a discoverer. Its practical result was that the way was shown to a very lucrative fishery in the "North Water" of Baffin's Bay, which continued to be frequented by a fleet of whalers every year. Captain Ross thought that the inlets reported by Baffin were merely bays, while the opinion of his second in command was that a wide opening to the westward existed through Lancaster Sound of Baffin.

Parry was consequently selected to command a new expedition in the following year. His two vessels, the "Hecla" and "Griper," passed through Lancaster Sound, the continuation of which he named Barrow Strait, and advanced westward, with an archipelago on his starboard hand, since known as the Parry Islands. He observed a wide opening to the north, which he named Wellington Channel, and sailed onwards for 300 miles to Melville Island. He was stopped by that impenetrable polar pack of vast thickness which appears to surround the archipelago to the north of the American continent, and was obliged to winter in a harbor on the south coast of Melville Island. Parry's sanitary arrangements during the winter were very judicious, and the scientific results of his expedition were most valuable. The vessels returned in October, 1820; and a fresh expedition in the "Fury" and "Hecla," again under the command of Captain Parry, sailed from the Nore on May 8, 1821, and passed their first winter on the coast of the newly discovered Melville Peninsula in 66° 11' N. Still persevering, Parry passed his second winter among the Eskimo at Igloolik in 69° 20' N., and discovered a channel leading westward from the head of Hudson's Bay, which he named Fury and Hecla Strait. The expedition returned in the autumn of 1823. Meantime Parry's friend

Parry's first and second voyages.

Franklin had been employed in attempts to reach by land the northern shores of America, hitherto only touched at two points by Hearne and Mackenzie. Franklin went out in 1819, accompanied by Dr. Richardson, George Back, and Hood. They landed at York factory, and proceeded to the Great Slave Lake. In August of the following year they started for the Coppermine river, and, embarking on it, reached its mouth on July 18, 1821. From that point 550 miles of coast-line were explored, the extreme point being called Cape Turnagain. Most frightful sufferings, from starvation and cold, had to be endured during the return journey; but eventually Franklin, Richardson, and Back arrived safely at Port Chippewyan. It was now thought desirable that an attempt should be made to connect the Cape Turnagain of Franklin with the discoveries made by Parry during his second voyage; but the first effort, under Captain Lyon in the "Griper," was unsuccessful.

Franklin's first journey.

In 1824 three combined attempts were organized. While Parry again entered by Lancaster Sound and pushed down a great opening he had seen to the south named Prince Regent's Inlet, Captain Beechey was to enter Behring's Strait, and Franklin was to make a second journey to the shores of Arctic America. Parry was unfortunate, but Beechey entered Behring Strait in the "Blossom" in August, 1826, and extended our knowledge as far as Point Barrow in 71° 23' 30'' N. lat. Franklin, in 1825-26, descended the Mackenzie river to its mouth, and explored the coast for 374 miles to the westward; while Dr. Richardson discovered the shore between the mouths of the Mackenzie and Coppermine, and sighted land to the northward, named by him Wollaston Land, the dividing channel being called Union and Dolphin Strait. They returned in the autumn of 1826.

Parry's third voyage.

Beechey.

Franklin's second journey.

Work was also being done in the Spitzbergen and Barents Seas. From 1821 to 1824 the Russian Captain Lutke was surveying the west coast of Nova Zembla as far as Cape Nassau, and ex-

Lutke.

aming the ice of the adjacent sea. In May, 1823, the "Griper" sailed, under the command of Clavering. Captain Clavering, to convey Captain Sabine to the polar regions in order to make pendulum observations. Clavering pushed through the ice in 75° 30' N., and succeeded in reaching the east coast of Greenland, where observations were taken on Pendulum Island. He laid down the land from 76° to 72° N.

Parry's attempt in 1827 to reach the pole from the northern coast of Spitzbergen, by means of sledge-boats, has been described under the heading PARRY. The highest latitude reached was 82° 45' N.; and the attempt showed that it is useless to leave the land and trust to the drifting pack in polar exploration.

In 1829 the Danes undertook an interesting piece of exploration on the east coast of Greenland. Captain Graah of the Danish navy rounded Cape Farewell in boats, with four Europeans and twelve Eskimo. He advanced as far as 65° 18' N. on the east coast, where he was stopped by an insurmountable barrier of ice. He wintered at Nugarlik in 63° 22' N., and returned to the settlements on the west side of Greenland in 1830.

In the year 1829 Captain John Ross, with his nephew James, having been furnished with sufficient funds by a wealthy distiller named Felix Booth, undertook a private expedition of discovery in a small vessel called the "Victory." Ross proceeded down Prince Regent's Inlet to the Gulf of Boothia, and wintered on the eastern side of a land named by him Boothia Felix. In the course of exploring excursions during the summer months James Ross crossed the land and discovered the position of the north magnetic pole on the western side of it, on June 1, 1831. He also discovered a land to the westward of Boothia which he named King William Land, and the northern shore of which he examined. The most northern point, opposite the magnetic pole, was called Cape Felix, and thence the coast trended southwest to Victory Point. James Ross was at Cape Felix on May 29, 1830. The Rosses never could get their little vessel out of its winter quarters. They passed three winters there, and then fell back on the stores at Fury Beach, where they passed their fourth winter of 1832-33. Eventually they were picked up by a whaler in Barrow Strait, and brought home. Great anxiety was naturally felt at their prolonged absence, and in 1833 Sir George Back, with Dr. Richard King as a companion, set out by land in search of the missing explorers. Wintering at the Great Slave Lake, he left Fort Reliance on June 7, 1834, and descended the Great Fish River, which is obstructed by many falls in the course of a rapid and tortuous course of 530 miles. The mouth was reached in 67° 11' N., when the want of supplies obliged them to return. In 1836 Sir George Back was sent, at the suggestion of the Royal Geographical Society, to proceed to Repulse Bay in his ship, the "Terror," and then to cross an assumed isthmus and examine the coast-line thence to the mouth of the Great Fish River; but the ship was obliged to winter in the drifting pack, and was brought back across the Atlantic in a sinking condition.

The tracing of the polar shores of America was completed by the Hudson's Bay Company's servants. In June, 1837, Messrs. Simpson and Dease left Chippewyan, reached the mouth of the Mackenzie, and connected that position with Point Barrow, which had been discovered by the "Blossom" in 1826. In 1839 Simpson passed Cape Turnagain of Franklin, tracing the coast eastward so as to connect with Back's work at the mouth of the Great Fish River. He landed at Montreal Island in the mouth of that river, and then advanced eastward as far as Castor and Pollux river, his farthest eastern point. On his return he travelled along the

north side of the channel, which is in fact the south shore of the King William Island discovered by James Ross. The southwestern point of this island was named Cape Herschel, and there Simpson built a cairn on August 26, 1839. Very little more remained to be done in order to complete the delineation of the northern shores of the American continent. This was entrusted to Dr. John Rae, a Hudson's Bay factor, in 1846. He went in boats to Repulse Bay, where he wintered in a stone hut nearly on the Arctic Circle; and he and his six Orkney men maintained themselves on the deer they shot. During the spring of 1847 Dr. Rae explored on foot the shores of a great gulf having 700 miles of coast-line. He thus connected the work of Parry, at the mouth of Fury and Hecla Strait, with the work of Ross on the coast of Boothia, proving that Boothia was part of the American continent.

While the English were thus working hard to solve some of the geographical problems relating to Arctic America, the Russians were similarly engaged in Siberia. In 1821 Lieutenant Anjou made a complete survey of the New Siberia Islands, and came to the conclusion that it was not possible to advance far from them in a northerly direction, owing to the thinness of the ice and to open water within 20 or 30 miles. Baron Wrangell prosecuted similar investigations from the mouth of the Kolyma between 1820 and 1823. He made four journeys with dog sledges, exploring the coast between Cape Tchelagskoi and the Kolyma, and making attempts to extend his journeys to some distance from the land. He was always stopped by thin ice, and he received tidings from a native chief of the existence of land at a distance of several leagues to the northward. In 1843 Middendorf was sent to explore the region which terminates in Cape Tchelyuskin. He reached the cape in the height of the short summer, whence he saw open water and no ice blink in any direction. The whole arctic shore of Siberia had now been explored and delineated, but no vessel had yet rounded the extreme northern point, by sailing from the mouth of the Yenisei to that of the Lena. When that feat was achieved the problem of the northeast passage would be solved.

The success of Sir James Ross's Antarctic expedition and the completion of the northern coast-line of America by the Hudson's Bay Company's servants gave rise in 1845 to a fresh attempt to make the passage from Lancaster Sound to Behring Strait. The story of this unhappy expedition of Sir John Franklin, in the "Erebus" and "Terror," has already been told under FRANKLIN (*q.v.*); but some geographical details may be given here.

To understand clearly the nature of the obstacle which finally stopped Sir John Franklin, and which also stopped Sir Edward Parry in his first voyage, it is necessary to refer to the map. Westward of Melville and Baring Islands, northward of the western part of the American coast, and northward of the channel leading from Smith Sound, there is a vast unknown space, the ice which encumbers it never having been traversed by any ship. All navigators who have skirted along its edge describe the stupendous thickness and massive proportions of the vast floes with which it is packed. This accumulation of ice of enormous thickness, to which Sir George Nares has given the name of a "Palæocrystic Sea," arises from the absence of direct communication between this portion of the north polar region and the warm waters of the Atlantic and Pacific. Behring Strait is the only vent in a southwesterly direction, and that channel is so shallow that the heavy ice grounds outside it. In other directions the channels leading to Baffin's Bay are narrow and tortuous. In one place only is there a wide and straight lead. The heavy polar ice flows

southeast between Melville and Baring Islands, down what is now called M'Clintock Channel, and impinges on the northwest coast of the King William Land discovered by James Ross. It was this branch from the palæocrystic sea which finally stopped the progress of Franklin's expedition. On leaving the winter-quarters at Beechey Island in 1846, Franklin found a channel leading south, along the western shore of the land of North Somerset discovered by Parry in 1819. If he could reach the channel on the American coast, he knew that he would be able to make his way along it to Behring Strait. This channel leading south, now called Peel Sound, pointed directly to the south. He sailed down it towards King William Island, with land on both sides. But directly they passed the southern point of the western land, and were no longer shielded by it, the great palæocrystic stream from Melville Island was fallen in with, pressing on King William Island. It was impassable. The only possibility of progress would have been by rounding the eastern side of King William Island, but its insularity was then unknown.

It was not until 1848 that anxiety began to be felt about the Franklin expedition. In the spring of that year Sir James Ross was sent with two ships, the "Enterprise" and "Investigator," by way of Lancaster Sound. He wintered at Leopold Harbor, near the northeast point of North Devon. In the spring he made a long sledge journey with Lieutenant M'Clintock along the northern and western coasts of North Somerset.

On the return of the Ross expedition without any tidings, the country became thoroughly alarmed. An extensive plan of search was organized,—the "Enterprise" and "Investigator" under Collinson and M'Clure proceeding by Behring Strait, while the "Assistance" and "Resolute" with two steam tenders, the "Pioneer" and "Intrepid," sailed May 3, 1850, to renew the search by Barrow Strait, under Captain Austin. Two brigs, the "Lady Franklin" and "Sophia," under Captain Penny, a very energetic and able whaling captain, were sent by the same route. He had with him Dr. Sutherland, a naturalist, who did much valuable scientific work. Austin and Penny entered Barrow Strait, and Franklin's winter quarters of 1845-46 were discovered at Beechey Island; but there was no record of any kind indicating the direction taken by the ships. Stopped by the ice Austin's expedition wintered (1850-51) in the pack off Griffith Island, and Penny found refuge in a harbor on the south coast of Cornwallis Island. Austin, who had been with Parry during his third voyage, was an admirable organizer. His arrangements for passing the winter were carefully thought out and answered perfectly. In concert with Penny he planned a thorough and extensive system of search by means of sledge travelling in the spring; and Lieutenant M'Clintock superintended every minute detail of this part of the work with unflinching forethought and consummate skill. Penny undertook the search by Wellington Channel. M'Clintock advanced to Melville Island, marching over 770 miles in eighty-one days; Captain Ommanney and Sherard Osborn pressed southward and discovered Prince of Wales Island. Lieutenant Brown examined the western shore of Peel Sound. The search was exhaustive; but, except the winter quarters at Beechey Island, no record, no sign was discovered. The absence of any record made Captain Austin doubt whether Franklin had ever gone beyond Beechey Island. So he also examined the entrance of Jones Sound, the next inlet from Baffin's Bay north of Lancaster Sound, on his way home, and returned to England in the autumn of 1851. This was a thoroughly well-conducted expedition,—especially as regards the sledge travelling, which M'Clintock brought to great perfection. So far as the search for Franklin

was concerned, nothing remained to be done, west or north of Barrow Strait.

In 1851 the "Prince Albert" schooner was sent out by Lady Franklin, under Captain Kennedy, with Lieutenant Bellot of the French navy as second. They wintered on the east coast of North Somerset, and in the spring of 1852 the gallant Frenchman, in the course of a long sledging journey, discovered Bellot. Bellot Strait separating North Somerset from Boothia,—this proving that the Boothia coast facing the strait was the northern extremity of the continent of America.

The "Enterprise" and "Investigator" sailed from England in January, 1850, but accidentally parted company before they reached Behring Strait. On May 6, 1851, the "Enterprise" passed the strait, and rounded Point Barrow on the 25th. Collinson then made his way up the narrow Prince of Wales Strait, between Baring and Prince Albert Island, and reached Princess Royal Islands, where M'Clure had been the previous year. Returning southwards, the "Enterprise" wintered in a sound in Prince Albert Island in 71° 35' N. and 117° 35' W. Three travelling parties were despatched in the spring of 1852,—one to trace Prince Albert Land in a southerly direction, while the others explored Prince of Wales Strait, one of them reaching Melville Island. In September, 1852, the ship was free, and Collinson pressed eastward along the coast of North America, reaching Cambridge Bay (September 26), where the second winter was passed. In the spring he examined the shores of Victoria Land as far as 70° 26' N. and 100° 45' W. He was within a few miles of Point Victory, where the fate of Franklin would have been ascertained. The "Enterprise" again put to sea on August 5, 1853, and returned westward along the American coast, until she was stopped by ice and obliged to pass a third winter at Camden Bay, in 70° 8' N. and 145° 29' W. In 1854 this most remarkable voyage was completed, and Captain Collinson brought the "Enterprise" back to England.

Meanwhile M'Clure in the "Investigator" had passed the winter of 1850-51 at the Princess Royal Islands, only 30 miles from Barrow Strait. In October M'Clure ascended a hill whence he could see the frozen surface of Barrow Strait which was navigated by Parry in 1819-20. Thus, like the survivors of Franklin's crews when they reached Cape Herschel, M'Clure discovered a northwest passage. It was impossible to reach it, for the branch of the palæocrystic ice which stopped Franklin off King William Land was athwart their northward course. So, as soon as he was free in 1851, M'Clure turned southwards, round the southern extreme of Baring Island, and commenced to force a passage to the northward between the western shore of that land and the enormous fields of ice which pressed upon it. The cliffs rose up like walls on one side, while on the other the stupendous ice of the palæocrystic sea rose from the water to a level with the "Investigator's" lower yards. After many hair-breadth escapes M'Clure took refuge in a bay on the northern shore of Bank's Land, which he named "The Bay of God's Mercy." Here the "Investigator" remained, never to move again. After the winter of 1851-52 M'Clure made a journey across the ice to Melville Island, and left a record at Parry's winter harbor. Abundant supplies of musk ox were fortunately obtained, but a third winter had to be faced. In the spring of 1853 M'Clure was preparing to abandon the ship with all hands, and attempt, like Franklin's crews, to reach the American coast. But succor providentially arrived in time.

The Hudson's Bay Company assisted in the search for Franklin. In 1848 Sir John Richardson and Dr. Rae examined the American coast from the mouth of the Mackenzie to

that of the Coppermine. In 1849 and 1850 Rae continued the search; and by a long sledge journey in the spring of 1851, and a boat voyage in the summer, he examined the shores of Wollaston and Victoria Lands, which were afterwards explored by Captain Collinson in the "Enterprise."

In 1852 the British Government resolved to despatch another expedition by Lancaster Sound. Austin's four vessels were recommissioned, and the "North Star" was sent out as a *dépôt* ship at Beechey Island.

Sir Edward Belcher commanded the "Assistance," with the "Pioneer" under Sherard Osborn as steam tender. He went up Wellington Channel to Northumberland Bay, where he wintered, passing a second winter lower down in Wellington Channel, and then abandoning his ships and coming home in 1854. But Sherard Osborn and Commander Richards did good work.

They made sledge journeys to Melville Island, and thus discovered the northern side of the Parry group. Captain Kellett received command of the "Resolute," with M'Clintock in the steam tender "Intrepid." Among Kellett's officers were the best of Austin's sledge travellers, M'Clintock, Meham, and Vesey Hamilton, so that good work was sure to be done. George Nares, the future leader of the expedition of 1874-75, was also on board the "Resolute." Kellett passed onwards to the westward and passed the winter of 1852-53 at Melville Island. During the autumn Meham discovered M'Clure's record, and the position of the "Investigator" was thus ascertained. The safety of her crew was consequently assured, for it was only necessary to send a message across the strait between two fixed positions. This service was performed by Lieutenant Pim early in the following spring. The officers and crew of the "Investigator," led by M'Clure, arrived safely on board the "Resolute" on June 17, 1853, and they reached England in the following year. They not only discovered but traversed a northwest passage, though not in the same ship, and partly by travelling over ice. For this great feat M'Clure received the honor of knighthood,—a reward of £10,000 being granted to himself, the other officers, and the crew, by a vote of the House of Commons.

The travelling parties of Kellett's expedition, led by M'Clintock, Meham, and Vesey Hamilton, completed the discovery of the northern and western sides of Melville Island, and the whole outline of the large Island of Prince Patrick, still further to the westward. M'Clintock was away from the ship with his sledge party for one hundred and five days and travelled over 1328 miles. Meham was away ninety-four days and travelled over 1163 miles. Sherard Osborn, in 1853, was away ninety-seven days and travelled over 935 miles. The "Resolute" was obliged to winter in the pack in 1853-54, and in the spring of 1854 Meham made a most remarkable journey in the hope of obtaining news of Captain Collinson at the Princess Royal Islands. Leaving the ship on 3d April he was absent seventy days, out of which there were sixty-one and a half days of travelling. The distance gone over was 1336 statute miles. The average rate of the homeward journey was $23\frac{1}{2}$ miles a day, the average time of travelling each day nine hours twenty-five minutes. This journey is without a parallel in arctic records.

Fearing detention for another winter, Sir Edward Belcher ordered all the ships to be abandoned in the ice, the officers and crews being taken home in the "North Star," and in the "Phoenix" and "Talbot" which had come out from England to communicate.

They reached home in October, 1854. In 1852 Captain Inglefield, R.N., had made a voyage of Baffin's Bay in the "Isabel" as far as the entrance of Smith Sound. In 1853 and

1854 he came out in the "Phoenix" to communicate with the "North Star" at Beechey Island. The drift of the "Resolute" was a remarkable proof of the direction of the current out of Barrow Strait. She was abandoned in $74^{\circ} 41' N.$ and $101^{\circ} 11' W.$ on May 14, 1854. On September 10, 1855, an American whaler sighted the "Resolute" in $67^{\circ} N.$ lat, about twenty miles from Cape Mercy, in Davis Strait. She was brought into an American port, and eventually presented to the British Government. She had drifted nearly a thousand miles.

In 1853 Dr. Rae was employed to connect a few points which would quite complete the examination of the coast of America, and establish the insularity of King William Land. He went up Chesterfield Inlet and the river Quioich for a considerable distance, wintering with eight men at Repulse Bay in a snow house. Venison and fish were abundant. In 1854 he set out on a journey which occupied fifty-six days in April and May. He succeeded in connecting the discoveries of Simpson with those of James Ross, and thus established the fact that King William Land was an island. Rae also brought home tidings and relics of Franklin's expedition gathered from the Eskimo; and this led to the expedition of M'Clintock in the "Fox," already described in the article FRANKLIN (vol. ix. p. 635). While M'Clintock was prosecuting his exhaustive search over part of the west coast of Boothia, the whole of the shores of King William Island, the mouth of the Great Fish River, and Montreal Island, Allen Young completed the discovery of the southern side of Prince of Wales Island. The "Fox" returned to England in the autumn of 1859.

The catastrophe of Sir John Franklin's expedition led to 7000 miles of coast-line being discovered, and to a vast extent of unknown country being explored, securing very considerable additions to geographical knowledge. Much attention was also given to the collection of information, and the scientific results of the various search expeditions were considerable. The catastrophe also afforded a warning which would render any similar disaster quite inexcusable. If arrangements are always carefully made for a retreat beforehand, if a *dépôt* ship is always left within reach of the advancing expedition as well as of the outer world, and if there is annual communication, with positive rules for depositing records, no such catastrophe can ever happen again.

The American nation was first led to take an interest in polar research through a very noble and generous feeling of sympathy for Franklin and his brave companions. Mr. Grinnell of New York gave practical expression to this feeling. In 1850 he equipped two vessels, the "Advance" and "Rescue," to aid in the search, commanded by Lieutenants DeHaven and Griffith, and accompanied by Dr. Kane. They reached Beechey Island on August 27, 1850, and assisted in the examination of Franklin's winter-quarters, but returned without wintering. In 1853 Dr. Kane, in the little brig "Advance" of 120 tons, undertook to lead an American expedition up Smith Sound, the most northern outlet from Baffin's Bay. The "Advance" reached Smith Sound on the 7th August, 1853, but was stopped by ice in $78^{\circ} 45' N.$, only seventeen miles from the entrance. He described the coast as consisting of precipitous cliffs 800 to 1200 feet high, and at their base there was a belt of ice about 18 feet thick, resting on the beach. Dr. Kane adopted the Danish name of "ice foot" (*is fod*) for this permanent frozen ridge. He named the place of his winter-quarters Van Rensselaer Harbor. In the spring some interesting work was done. A great glacier was discovered

and named the Humboldt glacier, with a sea face 45 miles long. Dr. Kane's steward, Morton, crossed the foot of this glacier with a team of dogs, and reached a point of land beyond named Cape Constitution. But sickness and want of means prevented much from being done by travelling parties. Scurvy attacked the whole party during the second winter, although the Eskimo supplied them with fresh meat and were true friends in need. On May 17, 1855, Dr. Kane abandoned the brig, and reached the Danish settlement of Upernivik on 6th August. Lieutenant Hartstene, who was sent out to search for Kane, reached Van Rensselear Harbor after he had gone, but took the retreating crew on board on his return voyage.

On July 10, 1860, Dr. Hayes,¹ who had served with Kane, sailed from Boston for Smith Sound in the schooner "United States" of 130 tons and a crew of fifteen men. His object was to follow up the line of research opened by Dr. Kane. He wintered at Port Foulke, in $78^{\circ} 17' N.$, and about ten miles from Cape Alexander, which forms the eastern portal of Smith Sound. Dr. Hayes crossed Smith Sound in the spring with dog-sledges, but his observations are not to be depended on, and it is very uncertain how far he advanced northwards on the other side. He returned to Boston on October 23, 1861.

The story of Charles Hall of Cincinnati, who was led to become an arctic explorer through his deep interest in the search for Franklin, has been told in the article devoted to him (vol. xi. p. 347). In his first journey (1860-62) he discovered the interesting remains of a stonehouse which Sir Martin Frobisher built on the Countess of Warwick Island in 1578. In his second expedition (1864-69), Hall by dint of the most unwearied perseverance at length reached the line of the retreat of the Franklin survivors at Todd's Island and Peffer river, on the south coast of King William Island. He heard the story of the retreat and of the wreck of one of the ships from the Eskimo; he was told that seven bodies were buried at Todd Island; and he brought home some bones which are believed to be those of Lieutenant Le Vescomte of the "Erebus." Finally, in 1871, he took the "Polaris" for 250 miles up the channel which leads northwards from Smith Sound. The various parts of this long channel are called Smith Sound, Kane Basin, Kennedy Channel, and Robeson Channel. The "Polaris" was beset in $82^{\circ} 16' N.$ on 30th August; and her winter-quarters were in $81^{\circ} 38' N.$, called Thank God Bay. The death of Hall and the subsequent fortunes of the expedition have been described in the article above cited.

The Spitzbergen seas have been explored, in recent years, by Norwegian fishermen as well as by Swedish and German expeditions and by English yachtsmen. The Norwegian Spitzbergen fishery dates from 1820, but it is only in recent years that Professor Mohn of Christiania has watched over the voyages and carefully collected information from the captains. In 1863 Captain Carlsen circumnavigated the Spitzbergen group for the first time in a brig called the "Jan Mayen." In 1864 Captain Tobiesen sailed round Northeast Land. In 1872 Captains Altmann and Nils Johnsen visited Wiche's Land, which was discovered by Captain Edge in 1617. In that year there were twenty-three sailing vessels from Tromsø, twenty-four from Hammerfest, and one from Vardö engaged in the arctic sealing trade. They average from 35 to 40 tons, and carry a dozen men. There were also eight vessels from Tromsø shark-fishing for cod-liver oil, and fifty from Hammerfest and Vardö. Since 1869 the Norwegians have extended their voyages to Nova Zembla. In that year Carlsen crossed the sea of Kara and reached the mouth of the Obi. In 1870 there were about sixty Norwegian vessels in the Barents Sea, and Captain Johannesen circumnavigated Nova Zembla.

In 1873 Captain Tobiesen was unfortunately obliged to winter on the Nova Zembla coast, owing to the loss of his schooner, and both he and his young son died of scurvy in the spring. Two years previously Captain Carlsen had succeeded in reaching the winter-quarters of Barents, the first visitor since 1597, an interval of two hundred and seventy-four years. He landed on September 9, 1871, and found the house still standing and full of interesting relics, which are now in the naval museum at the Hague.

Between 1858 and 1872 the Swedes sent seven expeditions to Spitzbergen and two to Greenland. All returned with valuable scientific results. That of 1864 under Nordenskiöld and Duner made observations at eighty different places on the Spitzbergen shores, and fixed the heights of numerous mountains. In 1868, in an iron steamer, the "Sophia," the Swedes attained a latitude of $81^{\circ} 42' N.$ on the meridian of $18^{\circ} E.$ during the month of September. In 1872 an expedition consisting of the "Polhem" steamer and brig "Gladen," commanded by Professor Nordenskiöld and Lieutenant Palander, wintered in Mussel Bay, on the northern shore of Spitzbergen. In the spring an important sledging journey of sixty days' duration was made over Northeast Land. The expedition was in some distress as regards provisions owing to two vessels, which were to have returned, having been forced to winter. But in the summer of 1873 they were visited by Mr. Leigh Smith, in his yacht "Diana," who supplied them with fresh provisions.

Dr. Petermann of Gotha urged his countrymen to take their share in the noble work of polar discovery, and at his own risk he fitted out a small vessel called the "Germania," which sailed from Bergen, in May, 1868, under the command of Captain Koldewey. His cruise extended to Hinlopen Strait in Spitzbergen, but was merely tentative; and in 1870 Baron von Heuglin with Count Zeil explored the Stor Fjord in a Norwegian schooner, and also examined Walter Thymen's Strait. After the return of the "Germania" in 1868 a regular expedition was organized under the command of Captain Koldewey, provisioned for two years. It consisted of the "Germania" a screw steamer of 140 tons, and the brig "Hansa," commanded by Captain Hegemann. Lieutenant Payer, the future discoverer of Franz Josef Land, gained his first arctic experience on board the "Germania." The expedition sailed from Bremen on the 15th June, 1869, its destination being the east coast of Greenland. But in latitude $70^{\circ} 46' N.$ the "Hansa" got separated from her consort and crushed in the ice. The crew built a house of patent fuel on the floe, and in this strange abode they passed their Christmas. In two months the current had carried them south for 400 miles. By May they had drifted 1100 miles on their ice-raft, and finally, on June 14, 1870, they arrived safely at the Moravian mission station of Friedriksthal, to the west of Cape Farewell. Fairer fortune attended the "Germania." She sailed up the east coast of Greenland as high as $75^{\circ} 30' N.$, and eventually wintered at the Pendulum Islands of Clavering in $74^{\circ} 30' N.$ In March, 1870, a travelling party set out under Koldewey and Payer, and reached a distance of 100 miles from the ship to the northward, when want of provisions compelled them to return. A grim cape, named after Prince Bismarck, marked the northern limit of their discoveries. As soon as the vessel was free, a deep branching fjord was discovered in $73^{\circ} 15' N.$ stretching for a long distance into the interior of Greenland. Along its shore are peaks 7000 and 14,000 feet high. The expedition returned to Bremen on September 11, 1870.

Lieutenant Payer was resolved to continue in the path of polar discovery. He and a naval officer named Weyprecht freighted a Norwegian schooner called the "Isbjörn," and

tions.

Koldewey.

Payer and
Weyprecht.

¹ [Isaac I. Hayes (1832-81), a Pennsylvania physician, Union army surgeon in the Civil War, explored in Greenland (1869), published books of his adventures. Died in New York.—AM. Ed.]

examined the edge of the ice between Spitzbergen and Nova Zembla, in the summer of 1871. Their observations led them to select the route by the north end of Nova Zembla with a view to making the northeast passage. It was to be an Austria-Hungarian expedition, and the idea was seized with enthusiasm by the whole empire. Weyprecht was to command the ship, while Julius Payer conducted the sledge parties. The steamer "Tegethoff," of 300 tons, was fitted out in the Elbe, and left Tromsø on July 14, 1872. The season was exceptionally severe, and the vessel was closely beset near Cape Nassau, at the northern end of Nova Zembla, in the end of August. The summer of 1873 found her still a close prisoner drifting, not with a current, but in the direction of the prevailing wind. At length, on the 31st August, a mountainous country was sighted about 14 miles to the north. In October the vessel was drifted within 3 miles of an island lying off the main mass of land. Payer landed on it, and found the latitude to be 79° 54' N. It was named after Count Wilczek, one of the warmest friends of the expedition. Here the second winter was passed. Bears were very numerous and as many as sixty-seven were killed, their meat proving to be a most efficient remedy against scurvy. In March, 1874, Payer made a preliminary sledge journey in intense cold (thermometer at -58° F.). On 24th March he started for a more prolonged journey of thirty days. Payer found that the newly discovered country equalled Spitzbergen in extent, and consisted of two or more large masses—Wilczek Land to the east, Zichy Land to the west, intersected by numerous fjords, and skirted by a large number of islands. A wide channel, named Austria Sound, separates the two main masses of land, and extends to 82° N., where Rawlinson Sound forks off to the northeast. The mountains attain a height of 2000 to 3000 feet, the depressions between them being covered with glaciers; and all the islands even are covered with a glacial cap. The whole country was named Franz-Josef Land. Payer returned to the "Tegethoff" on 24th April; and a third journey was undertaken to explore a large island named after M'Clintock. It then became necessary to abandon the ship and attempt a retreat in boats. This perilous voyage was commenced on 20th May. Three boats stored with provisions were placed on sledges. It was not until 14th August that they reached the edge of the pack in 77° 40' N., and launched the boats. Eventually they were picked up by a Russian schooner and arrived at Vardø on September 3, 1874. This great achievement is one of the most important connected with the north polar region that has been made in the present century, and will probably lead in due time to still further discoveries in the same direction.

One of the most interesting problems connected with the physical geography of the polar regions is the history and actual condition of the vast interior of Greenland, which is generally believed to be one enormous glacier. In 1867 Mr. Edward Whymper carefully planned an expedition to solve the question, and went to Greenland, accompanied by Dr. Robert Brown;¹ but the season was too late, and progress was stopped, after going a short distance, by the breaking down of the dog-sledges. But Dr. Brown made most valuable geological and natural history collections, chiefly in the neighborhood of Disco, and still more valuable observations, the publication of which has added considerably to our knowledge. Dr. Rink, for many years royal inspector of South Greenland and the most distinguished authority on all Greenlandic questions, has also visited the inland ice, and has given his stores of information to the world. The most important inland journey was undertaken by Professor Nordenskiöld in 1870, accompanied by Dr. Berggren, the professor of botany at Lund. The difficulty of traversing the inland ice of Greenland is caused by the vast glacier being in constant motion,

advancing slowly towards the sea. This movement gives rise to huge chasms and clefts, which from their almost bottomless depth close the traveller's way. The chasms occur chiefly where the movement of the glacier is most rapid, near the ice streams which reach the sea and discharge glaciers. Nordenskiöld, therefore, chose for a starting point the northern arm of a deep inlet called Auletsivikfjord, which is 60 miles south of the discharging glacier at Jakobshavn and 240 north of that at Godthaab. He commenced his inland journey on 19th July. The party consisted of himself, Dr. Berggren, and two Greenlanders; and they advanced 30 miles over the glaciers to a height of 2200 feet above the sea.

The gallant enterprises of other countries rekindled the zeal of England for arctic discovery; and in October, 1874, the prime minister announced that an expedition would be despatched in the following year. The route by Smith Sound was selected because it gave the certainty of exploring a previously unknown area of considerable extent, because it yielded the best prospect of valuable scientific results, and because it offered, with proper precautions, reasonable security for a safe retreat in case of disaster.

Two powerful screw steamers, the "Alert" and "Discovery," were selected for the service, and Captain Nares was selected as leader. Commander Markham, who had made a cruise up Baffin's Bay and Barrow Strait in a whaler during the previous year, Lieutenant Aldrich, an accomplished surveyor, and Captain Feilden, R.A., as naturalist, were also in the "Alert." The "Discovery" was commanded by Captain Stephenson, with Lieutenant Beaumont as first lieutenant. The expedition left Portsmouth on the 29th May, 1875, and entered Smith Sound in the last days of July. After much difficulty with the drifting ice Lady Franklin Bay was reached in 81° 44' N., where the "Discovery" was established in winter-quarters. The "Alert" pressed onwards, and reached the edge of the palæocrystic sea, the ice-floes being from 80 to 100 feet in thickness. Leaving Robeson Channel, the vessel made progress between the land and the grounded floe pieces, and passed the winter off the open coast and facing the great polar pack in 82° 27' N. Autumn travelling parties were despatched in September and October to lay out depôts; and during the winter a complete scheme was matured for the examination of as much of the unknown area as possible, by the combined efforts of sledging parties from the two ships, in the ensuing spring. The parties started on April 3, 1876. Captain Markham with Lieutenant Parr advanced, in the face of almost insurmountable difficulties, over the polar pack to the high latitude of 83° 20' 26" N. Lieutenant Aldrich explored the coast-line to the westward, facing the frozen polar ocean, for a distance of 220 miles. Lieutenant Beaumont made discoveries of great interest along the northern coast of Greenland. The parties were attacked by scurvy, which, while increasing the difficulty and hardships of the work a hundredfold, also enhanced the devoted heroism of these gallant explorers. Captain Feilden was indefatigable in making collections, and was zealously assisted by all the officers. The expedition returned to England in October, 1876. The "Alert" reached the highest northern latitude ever attained by any ship, and wintered further north than any ship had ever wintered before. The results of the expedition were the discovery of 300 miles of new coast-line, the examination of this part of the frozen polar ocean, a series of meteorological, magnetic, and tidal observations at two points farther north than any such observations had ever been taken before, and large geological and natural history collections.

In the same year, 1875, Sir Allen Young undertook a voyage in his steam yacht the "Pandora," to attempt to force his way down Peel Sound to the magnetic pole, and if possible

Nordenskiöld in Greenland.

¹ Born 23d Mar., 1842, died 26th Oct., 1895. He traveled extensively in N. Africa and elsewhere; lectured on Botany, Zoology and Geology in various institutions; wrote about 30 vols. on scientific subjects, and nearly 4000 articles for reviews, etc.

English expedition of 1875.

Voyages of the "Pandora."

to make the northwest passage by rounding the eastern shore of King William Island. The "Pandora" entered Peel Sound on August 29, 1875, and proceeded down it much farther than any vessel had gone before since it was passed by Franklin's two ships in 1846. Sir Allen reached a latitude of 72° 14' N., and sighted Cape Bird, at the northern side of the western entrance of Bellot Strait. But here an ice-barrier right across the channel barred his progress, and he was obliged to retrace his steps, returning to England on October 16, 1875. In the following year Sir Allen Young made another voyage in the "Pandora" to the entrance of Smith Sound.

Lieutenant Koolemans Beynen, a young Dutch officer, who had shared Young's two polar voyages, on his return successfully endeavored to interest his countrymen in polar discovery. It was wisely determined that the first expeditions of Holland should be summer reconnaissances on a small scale. A sailing schooner of 79 tons was built at Amsterdam, and named the "Willem Barents." In her first cruise she was commanded by Lieutenant A. de Bruyne, with Koolemans Beynen as second, and she sailed from Holland on the 6th May, 1878. Her instructions were to examine the ice in the Barents and Spitzbergen Seas, take deep-sea soundings, and make natural history collections. She was also to erect memorials to early Dutch polar worthies at certain designated points. These instructions were ably and zealously carried out. Beynen died in the following year, but the work he initiated has been continued. Every year from 1878 to 1884 the "Willem Barents" has made a polar voyage, and has brought back useful scientific results. In 1879 the Dutch succeeded in sighting the coast of Franz-Josef Land.

In 1879 Sir Henry Gore-Booth, Bart., and Captain A. H. Markham, R. N., undertook a polar cruise in the Norwegian schooner "Isbjörn." They sailed along the west coast of Nova Zembla to its most northern point, passed through the Matotchkin Shar to the east coast, and examined the ice in the direction of Franz-Josef Land as far as 78° 24' N. Captain Markham brought home collections in various branches of natural history, and made useful observations on the drift and nature of the ice in the Barents and Kara Seas.

In 1880 Mr. Leigh Smith, who had previously made three voyages to Spitzbergen, reached Franz-Josef Land in the screw steamer "Eira." It was observed that, while the Greenland icebergs are generally angular and peaked, those of Franz-Josef Land are vast masses quite flat on the top, like the Antarctic bergs, and from 150 to 200 feet high. The "Eira" sailed along the land to the westward, and discovered 110 miles of new coast line as far as the western extreme of the south side of Franz-Josef Land, whence the land trended northwest. A landing was effected at several points, and valuable collections were made in natural history. In the following year the same explorer left Peterhead on July 14; Franz-Josef Land was once more sighted on the 23d July, and the "Eira" reached a point farther west than had been possible in her previous voyage. But in August the ship was caught in the ice, was nipped, and sank. A hut was built on shore in which Mr. Leigh Smith and his crew passed the winter of 1881-82; and on June 21, 1882, they started in four boats, to reach some vessels on the Nova Zembla coast. It was a most laborious and perilous voyage. They were first seen and welcomed by the "Willem Barents" on 2d August, and soon afterwards were taken on board the "Hope," a whaler which had come out for their rescue under the command of Sir Allen Young.

Professor Nordenskiöld, when he projected the achievement of the northeast passage, was a veteran polar explorer, for he had been in six previous expeditions to Greenland and Spitzbergen. In 1875 he turned his

attention to the possibility of navigating the seas along the northern coast of Siberia. Captain Wiggins of Sunderland was a pioneer of this route, and his voyages in 1874, 1875, and 1876 led the way to a trade between the ports of Europe and the mouth of the Yenisei river. In June, 1875, Professor Nordenskiöld sailed from Tromsö in the "Proven," reached the Yenisei by way of the Kara Sea, and discovered an excellent harbor on the eastern side of its mouth, which was named Port Dickson in honor of Mr. Oscar Dickson of Gothenburg, the munificent supporter of the Swedish expeditions. It having been suggested that the success of this voyage was due to the unusual state of the ice in 1875, Nordenskiöld undertook a voyage in the following year in the "Ymer" which was equally successful. By a minute study of the history of former attempts, and a careful consideration of all the circumstances, Professor Nordenskiöld convinced himself that the achievement of the northeast passage was feasible. The king of Sweden, Mr. Oscar Dickson, and M. Sibiriakoff, a wealthy Siberian proprietor, supplied the funds, and the steamer "Vega" was purchased. Nordenskiöld was leader of the expedition, Lieutenant Palander was appointed commander of the ship, and there was an efficient staff of officers and naturalists, including Lieutenant Hovgaard of the Dutch and Lieutenant Bove of the Italian navy. A small steamer called the "Lena" was to keep company with the "Vega" as far as the mouth of the Lena, and they sailed from Gothenburg on 4th July, 1878. On the morning of 10th August they left Port Dickson, and on the 19th they reached the most northern point of Siberia and of the Old World, Cape Severo or Tchelyuskin, in 77° 41' N. On leaving the extreme northern point of Asia a southeasterly course was steered, the sea being free from ice and very shallow. This absence of ice is due to the mass of warm water discharged by the great Siberian rivers during the summer. On 27th August the mouth of the river Lena was passed, and the "Vega" parted company with the little "Lena," continuing her course eastward. Professor Nordenskiöld very nearly made the northeast passage in one season. Towards the end of September the "Vega" was frozen in off the shore of a low plain in 67° 7' N. and 173° 20' W. near the settlements of the Tchukches. During the voyage very large and important natural history collections were made, and the interesting aboriginal tribe among whom the winter was passed was studied with great care. The interior was also explored for some distance. On July 18, 1879, after having been imprisoned by the ice for two hundred and ninety-four days, the "Vega" again proceeded on her voyage and passed Behring Strait on the 20th. Sir Hugh Willoughby made the first attempt in 1553. After a lapse of three hundred and twenty-six years, the northeast passage had at length been accomplished without the loss of a single life and without damage to the vessel. The "Vega" arrived at Yokohama on September 2, 1879.

In 1879 an enterprise was undertaken in the United States, with the object of throwing further light on the sad history of the retreat of Schwatka. the officers and men of Sir John Franklin's expedition, by examining the west coast of King William Island in the summer, when the snow is off the ground. The party consisted of Lieutenant Schwatka of the United States army and three others. Wintering near the entrance of Chesterfield Inlet in Hudson's Bay, they set out overland for the estuary of the Great Fish River, assisted by Eskimo and dogs, on April 1, 1879. They only took one month's provisions, their main reliance being upon the game afforded by the region to be traversed. The party obtained, during the journeys out and home, no less than five hundred and twenty-two reindeer. After collecting various stories from the Eskimo at Montreal Island and at an inlet west of Cape Richardson,

Dutch expeditions.

Gore-Booth and Markham.

Leigh Smith.

Nordenskiöld and the N. E. passage.

Schwatka crossed over to Cape Herschel on King William Island in June. He examined the western shore of the island with the greatest care for relics of Sir John Franklin's parties, as far as Cape Felix, the northern extremity. The return journey was commenced in November by ascending the Great Fish River for some distance and then marching over the intervening region to Hudson's Bay. The cold of the winter months in this country is intense, the thermometer falling as low as -70° ,—so that the return journey was most remarkable, and reflects the highest credit on Lieutenant Schwatka and his companions. As regards the search little was left to be done after McClintock, but some graves were found, as well as a medal belonging to Lieutenant Irving of H.M.S. "Terror," and some bones believed to be his, which were brought home and interred at Edinburgh.

Mr. Gordon Bennett, the proprietor of the *New York Herald*, having resolved to despatch an expedition of discovery at his own expense by way of Behring Strait, the "Pandora" was purchased from Sir Allen Young, and rechristened the "Jeannette." Lieutenant De Long of the United States navy was appointed to command, and it was made a national undertaking by special Act of Congress, the vessel being placed under martial law and officered from the navy. The "Jeannette" sailed from San Francisco on July 8, 1879, and was last seen steaming towards Wrangell Land on the 3d September. This land had been seen by Captain Kellett, in H.M.S. "Herald" on August 17, 1879, but no one had landed on it, and it was shown on the charts by a long dotted line. The "Jeannette" was provisioned for three years, but as no tidings had been received of her up to 1881, two steamers were sent up Behring Strait in search. One of these, the "Rodgers," under Lieutenant Berry, anchored in a good harbor on the south coast of Wrangell Land, in $70^{\circ} 57' N.$ on the 26th August, 1881. The land was explored by the officers of the "Rodgers" and found to be an island about 70 miles long by 28, with a ridge of hills traversing it east and west, the 71st parallel running along its southern shore. Lieutenant Berry then proceeded to examine the ice to the northward, and attained a higher latitude by 21 miles than had ever been reached before on the Behring Strait meridian, namely $73^{\circ} 44' N.$ Sir R. Collinson, in 1850, had reached $73^{\circ} 23' N.$ No news was obtained of the "Jeannette," but soon afterwards melancholy tidings arrived from Siberia. After having been beset in heavy pack ice for twenty-two months, the "Jeannette" was crushed and sunk on the 12th June, 1881, in $77^{\circ} 15' N.$ lat. and $155^{\circ} E.$ long. The officers and men dragged their boats over the ice to an island which was named Bennett Island, where they landed on the 29th July. They reached one of the New Siberia Islands on the 10th September, and on the 12th they set out for the mouth of the Lena. But in the same evening the three boats were separated in a gale of wind. A boat's crew with Mr. Melville, the engineer, reached Irkutsk, and Mr. Melville set out in search of Lieutenant De Long and his party, who had also landed. The other boat was lost. Eventually Melville discovered the dead bodies of De Long and two of his crew on March 23, 1883. They had perished from exhaustion and want of food. The "Rodgers" was burnt in its winter quarters, and one of the officers, Mr. Gilder, made a hazardous journey homewards through northeast Siberia.

The Danes had been very active in prosecuting discoveries and scientific investigations in Greenland, since the journey of Nordenskiöld in 1870. Lieutenant Jensen made a gallant attempt to penetrate the inland ice in 1878, and Professor Steenstrup, with Lieutenant Hammer, closely investigated the formation of ice masses at Omenak and Jacobshavn. In 1883 an ex-

pedition under Lieutenants Holm and Garde began to explore the east coast of Greenland, the discovery of the outline of which was completed in 1879. In the summer of that year Captain Mourier, of the Danish man of war "Ingulf," sighted the coast from the 6th to the 10th of July, and was enabled to observe and delineate it from $68^{\circ} 10' N.$ to $65^{\circ} 55' N.$, being exactly the gap left between the discoveries of Scoresby in 1822 and those of Graah in 1829. Lieutenant Hovgaard of the Danish navy, who accompanied Nordenskiöld in his discovery of the northeast passage, planned an expedition to ascertain if land existed to the north of Cape Tchelyuskin. He fitted out a small steamer called the "Dymphna" and sailed from Copenhagen in July, 1882, but was unfortunately beset and obliged to winter in the Kara Sea. In 1883 Baron Nordenskiöld undertook another journey over the inland ice of Greenland. Starting from Auleitsvikfjord on 4th July, his party penetrated 84 miles eastward, and to an altitude of 5000 feet. The Laplanders who were of the party were sent on snow-shoes 143 miles further, travelling over a desert of snow to a height of 7000 feet. Results in physical geography and biology were obtained which will render this unparalleled journey memorable.

On September 18, 1875, Lieutenant Weyprecht, one of the discoverers of Franz-Josef Land, read a thoughtful and carefully prepared paper before a large meeting of German naturalists at Gratz on the scientific results to be obtained from polar research and the best means of securing them. He urged the importance of establishing a number of stations within or near the Arctic Circle, in order to record complete series of synchronous meteorological and magnetic observations. Lieutenant Weyprecht did not live to see his suggestions carried into execution, but they bore fruit in due time. The various nations of Europe were represented at an international polar conference at Hamburg in 1879, and at another at St. Petersburg in 1882; and it was decided that each nation should establish one or more stations where synchronous observations should be taken from August, 1882. This useful project was matured and executed. The stations were at the following localities round the Arctic Circle:

Norwegians.....	Boskøp, Aften Fjord, Norway,	M. Aksel S. Steen.
Swedes.....	Ice Fjord, Spitzbergen.	Mr. Ekholm.
Dutch.....	Dickson Harbor, mouth of Yenisei, Siberia,	Dr. Smaller.
Russian.....	{ Sagastyr Island, mouth of Lena, Siberia,	Lieut. Jürgens.
	{ Möller Bay, Nova Zembla,	Lieut. Andreif.
Americans.....	{ Point Barrow, North America,	Lieut. Ray, U.S.A.
	{ Lady Franklin Bay, $81^{\circ} 44' N.$,	Lieut. Greely, U.S.A.
English.....	Great Slave Lake, Dominion of Canada,	Lieut. Dawson.
Germans.....	Cumberland Bay, west side of Davis Strait,	Dr. Giese.
Danes.....	Godthaab, Greenland,	A. Paulsen.

The whole scheme was successfully accomplished with the exception of the part assigned to the Dutch at Dickson Harbor. They started in the "Varna" but were beset in the Kara Sea and obliged to winter there. The "Varna" was lost, and the crew took refuge on board Lieutenant Hovgaard's vessel, which was also forced to winter in the pack during 1882-83.

The American stations commenced work in 1882. Lieutenant Greely's party consisted of two other lieutenants, of twenty sergeants and Greely. privates of the United States army, and of Dr. Pavy, an enthusiastic explorer who had been educated in France, and had passed the previous winter among the Eskimo of Greenland. On August 11, 1881, the steamer "Proteus" conveyed Lieutenant Greely and his party to Lady Franklin Bay during an exceptionally favorable season; a house was built at the "Discovery's" winter-quarters, and they were left with two years' provisions. The regular series of observations was at once commenced, and two winters were passed without accident. Travelling parties were also sent out in the

¹ [Melville gives long. 157° . Our *Lost Explorers*, R. L. Newcomb. Hartford, 1883, p. 85.—AM. Ed.]

summer, dogs having been obtained at Disco. Lieutenant Lockwood made a journey along the north coast of Greenland, and reached a small island in $83^{\circ} 24' N.$ and $44^{\circ} 5' W.$ ¹ Dr. Pavy and another went a short distance beyond the winter-quarters of the "Alert," and a trip was made into the interior of Grinnell Land. But all this region had already been explored and exhaustively examined by the English expedition in 1875-76.² The real value of the work of Lieutenant Greely's party will consist in the synchronous observations taken during 1882. As no succor arrived in the summer of 1883—though relieving vessels were dispatched both in 1882 and in 1883—Lieutenant Greely started from Lady Franklin Bay with his men on the 9th August, expecting to find a vessel in Smith Sound. On the 21st October they were obliged to encamp at Cape Sabine, on the western shore of Smith Sound, and build a hut for wintering. A few dépôts were found, which had been left by Sir George Nares and Lieutenant Beebe, but all was exhausted before the spring. Then came a time of indescribable misery and acute suffering. The poor fellows began to die of actual starvation; and, when the relieving steamers "Thetis" and "Bear" reached Cape Sabine, Lieutenant Greely and six suffering companions were found just alive. If the simple and necessary precaution had been taken of stationing a dépôt ship in a good harbor at the entrance of Smith Sound, in annual communication with Greely on one side and with America on the other, there would have been no disaster. If precautions proved to be necessary by experience are taken, there is no undue risk or danger in polar enterprise.

There is now no question as to the value and importance of polar discovery, and as to the principles on which expeditions should be sent out. Their objects are explorations for scientific purposes and the encouragement of maritime enterprise. The main principles have been briefly and clearly stated by Lieutenant Weyprecht: (1) arctic research is of the highest importance for a knowledge of nature's laws; (2) geographical research is valuable in proportion as it opens the field to scientific research generally; (3) the north pole has, for science, no greater significance than any other point in the higher latitudes. Lieutenant Weyprecht thus contends, as the council of the Royal Geographical Society has contended for years, that the attainment of the highest possible latitude or of the pole itself is not the object to be sought, but the exploration of the unknown area with a view to scientific results.

In planning a new polar expedition on an adequate scale it will be necessary to profit by the lessons of experience. This experience may be summed up in a few words. Any advanced ship or party must have a dépôt ship to fall back upon which is within reach, and also in communication with the outer world. This makes disaster on a large scale, humanly speaking, impossible. Every precaution that medical science can suggest must be taken against scurvy. An advancing expedition must always follow a coast line, because an entry into the drifting pack entails failure and probably loss of the ship. The coast-line should trend north with a westerly aspect, because a general motion of the sea towards the west causes the ice to set in that direction, unless deflected from purely local causes. Hence there are usually open lanes of water along the west sides of polar lands at some time of the navigable season, while the eastern sides are usually closed with ice. These well established canons point to the western side of Franz-Josef Land as the next region to be explored.

Physical Geography of the North Polar Regions.—Our ignorance of about 3,000,000 square miles within the north polar circle, out of a total area of 8,201,883, debars us from the possibility of considering the physical geography of the polar region as a whole. We can merely take stock of the isolated facts which our limited knowledge enables us to register.

As the physical condition of the whole area is mainly affected by the movements and positions of the ice masses, the temperature, and the circumstances which affect it, become the first and most fundamental elements for consideration. An examination of Dove's isothermal charts shows that the isotherms about the pole form ellipses tending to arrange themselves between two poles of cold, one in North America and the other in eastern Siberia. The mildest winters appear to be in the meridians of Behring Strait and the Spitzbergen seas. These temperatures appear to be mainly influenced by the extent of frozen land or fixed ice on the one hand and the neighborhood of open water and moving ice on the other. The following table shows the mean temperatures for the summer months, winter months, and whole year, at various stations in the archipelago north of the American continent:

Expedition.	Locality.	Latitude and Longitude.	Three Summer Months.	Three Winter Months.	Year.
M'Clure	Banks Island	$74^{\circ} 0' N. 118^{\circ} W.$	+35	-5.7	+1.8
Parry	Melville Island	$74^{\circ} 25' N. 111^{\circ} W.$	+37	-10.6	+1.4
Sutherland	Cornwallis Island	$74^{\circ} 45' N. 94^{\circ} W.$	+36	-8.6	+2.5
Belcher	Northumberland Sound	$77^{\circ} 0' N. 97^{\circ} W.$	+30.8	-11.8	-1.1
Parry	Port Bowen	$73^{\circ} 25' N. 89^{\circ} W.$	+36.9	-6.7	+4.3

At the Great Slave Lake in North America, Sir John Richardson found the mean of the three summer months to be $+49^{\circ}$, of the three winter months -0.8° , and of the year $+9^{\circ}$. On the west coast of Greenland the climate of the southernmost part resembles that of Iceland or the northern shores of Norway. It exhibits a gradually decreasing temperature throughout the whole of its extent to the north. The annual mean temperature at the southernmost station of Julianshaab is $+33^{\circ}$, and at the northernmost of Upernivik $+13^{\circ}$. The mean temperature of the three summer months for Julianshaab is $+48^{\circ}$ and for Upernivik $+43^{\circ}$; for the three winter months respectively $+20^{\circ}$ and -7° . The lowest temperature ever known at the Danish Greenland stations occurred at Upernivik and was -47° . Farther north on the west coast the "North Star," in 1851-52, observed the temperature for the year in Weistenholme Sound (lat. $76^{\circ} 30' N.$). For the three summer months the mean was $+37.8^{\circ}$, for the winter months -6.8° , and for the year $+4.5^{\circ}$. The most northern observations ever taken for a complete year were those of H.M.S. "Alert," at Floeberg Beach in $82^{\circ} 27' N.$ Synchronous observations were taken by H.M.S. "Discovery," in Lady Franklin Bay, lat. $81^{\circ} 44' N.$ The results were as follows:

Ship.	Latitude.	Summer.	Winter.	Year.
"Alert"	$82^{\circ} 27' N.$	+34	-36	-3
"Discovery"	$81^{\circ} 44' N.$	+33	-37	-4

The minimum temperatures were -73° , registered at Floeberg Beach in March, and -70° , at Lady Franklin Bay in the same month. These temperatures can be compared with the observations taken at Mossel Bay, on the north coast of Spitzbergen, by Nordenskiöld (lat. $79^{\circ} 54' N.$), and on the south coast of Franz-Josef Land by Weyprecht and Leigh Smith. At these stations the winters are less severe on account of the closer proximity of open water. In Franz-Josef Land the minimum in the winter months was -43° , and the mean was -26° ; in May the mean was $+22^{\circ}$. The climate on the coast of Siberia was registered at the winter quarters of the "Vega" in $67^{\circ} 7' N.$, the mean temperature of the three winter months being -10° , minimum -51° , and the mean of the three summer months $+36^{\circ}$; but the Siberian cold is far more intense inland.

The direction of the winds affects the temperatures and the movements of ice, but no general remarks upon them can be usefully made until our knowledge of the polar area is more complete. One of the most interesting features in polar winds is the instability

¹ [Lockwood Island is in long. $40^{\circ} 46' W.$, and more than 100 miles by coast N.E. of Cape Britannia. Sighted by Nares's expedition, 1875-6. See *Rescue of Greely*, by Schley and Soley, N. Y., 1885. Map.—AM. ED.]

² [The Greely expedition added to the Map of Grinnell Land Lake Hazen, a glacial lake connecting with Chandler Fiord, the Very river to a lake at the foot of Mt. Arthur, and Greely Fiord discovered by Lockwood, from the shores of which he sighted Cape Brainard which seemed to mark the western limit of Grinnell Land.—AM. ED.]

of the temperature caused by them over certain areas during the winter months. At Jacobshavn, in Greenland, the mean temperature in February was $+16^{\circ}$ in one year (1872), and -25° in another (1863), a difference of 41° . It was remarked that great rises in the winter temperatures occurred at a time when the wind was blowing from the interior glacier. This wind often turns into a sudden gale. Greenland is surrounded by regions which have extremely different winter temperatures. While on one side there is the intense cold of Arctic America and the Parry Islands, on the other, to the east-southeast, there is the warm temperature caused by the Gulf Stream; so that the Greenland climate is at all times dependent on the direction of the winds. All winds from south through west to northwest bring cold weather, but the east and southeast winds raise the temperature. The hot southeast winds of Greenland are caused in the same way as the "föhn" of the Alps. The interior glacier of Greenland rises to a height of at least 7000 feet. A warm wind from the Atlantic saturated with moisture could afford to lose considerably by cooling on its journey of 400 miles over the lofty ice deserts of Greenland, and yet arrive on the west coast with a comparatively high temperature. The influence of the Greenland föhn extends over a wide area. In 1875 there was a great rise of temperature at the Danish stations of Greenland; and Sir George Nares observed the same phenomenon, at nearly the same time, at his winter quarters in $82^{\circ} 17' N$. In Franz-Josef Land there are also great rises of temperature during the winter, with southerly winds accompanied by heavy falls of snow, as these winds come direct from expanses of open water caused by the current from the Atlantic.

Sea water, in the process of congelation, expels the salt, and its freezing point is about 28° . The ice first forms in thin, irregular flakes called "sludge," and when this is compact enough to hold snow it is known as "brash." Gathered into rounded masses it becomes "pancake ice," and soon it becomes thicker. The first thin covering is called by the whalers "bay ice." A "floe" is a sheet of ice the limits of which are visible. An "ice-field" differs from a floe in being so extensive that its limits cannot be seen. "Pack ice" consists of broken floes forced together by the wind or currents. When the pack is loosened and scattered by a wind from an opposite direction the pieces are called "sailing ice." The greatest thickness attainable by ice in one season is about 7 feet. The results of observations made by Sir George Nares in $82^{\circ} 17' N$, on the west side of Greenland and by Captain Koldewey on the east side in $74^{\circ} 30' N$, were identical, namely 6 feet 7 inches. Old ice is believed to become thicker in a second winter, and even to attain a thickness of 10 feet. In the paleocrystic sea there are floes from 80 to 100 feet thick, but these must be considered rather as sea-glaciers, formed by accumulations of snow on the ice year after year; and the smaller pieces broken from them have been very appropriately named floebergs. These mighty floes are sea-borne glaciers, perpetually wasting beneath and restored from above.

Icebergs are only met with where there are great discharging glaciers on the land, or in currents leading from them. Greenland is the principal mother of icebergs. This immense mass covers an area of about 512,000 square miles, and has 3400 miles of coastline. It is indented by deep channels or fjords, often extending more than 60 miles, with many islands and rocks along the coast. The whole of the interior is believed to be capped by an enormous glacier always moving towards the coast, and at certain points reaching the sea where masses break off in the shape of icebergs. These icebergs rise to a height of from 60 to 300 feet above the sea, with a circumference from several hundred to several thousand yards; and from seven to eight times the bulk seen above water is submerged, so that the weight of a large berg is millions of tons. When pieces break off from a parent iceberg the process is called "calving," and the pieces are "calf ice." Recent observation of one of the principal discharging glaciers of Greenland shows it to be 920 feet thick, and 13,400 feet wide, and that it advances at a rate of 47 feet a day during the summer season. In Spitzbergen and Nova Zembla there are much smaller glaciers discharging smaller berg pieces. The Franz-Josef Land glaciers produce large flat-topped icebergs, which do not, however, float southwards.

The movements of the polar seas are influenced by the currents, currents of seas and rivers which are constantly flowing northwards, and by ice-laden counter-currents which press through every strait and channel in the opposite direction. On the fringe of land forming the northern shores of Asia and America are the mouths of several great rivers. Of the Siberian rivers the Obi, with its affluent the Irtysh, has a basin covering 60,000 square miles, the Yenisei 50,000, and the Lena 40,000; but these areas are almost entirely within the temperate zone. In America the

rivers Mackenzie, Coppermine, and Great Fish (or Black) also pour their waters into the polar sea. The enormous volume of warm water which these rivers send into the ocean drives the heavy ice from the coast and, owing to the influence which the rotatory motion of the earth exercises, receives an easterly direction along the coast. Behring Strait is too narrow and too shallow to admit of any large flow from the Pacific, still there is a warm current which keeps the heavy ice at some distance and also flows easterly, its influence being felt beyond Point Barrow. The Norwegian current, usually considered to be a continuation of the Gulf Stream, conveys a large volume of water northwards along the coasts of Norway and Lapland, and keeps the ice at a distance from that shore throughout the winter. The polar currents flow southwards in the direction of the two great openings by Davis Strait and the sea on the east coast of Greenland, but the whole body appears eventually to find its way southwards by the former outlet. The current flowing south along the east coast of Greenland brings with it immense quantities of heavy ice, and when it reaches the south point of the land it turns westward and northward round Cape Farewell, until about $64^{\circ} N$, when it unites with the current coming from Baffin's Bay, and the united current, with its enormous quantity of ice and icebergs, flows south along the Labrador coast to Newfoundland. The other polar current flows southwards through all the channels and straits among the Parry Archipelago, and through Fury and Hecla Strait, down Baffin's Bay and Davis Strait.

The observations of various explorers lead to the conclusion that these outlets are insufficient to carry off the great harvests of ice, and that, in one part of the polar region, it continues to accumulate and form sea-borne glaciers. Collinson observed this formation off the coast of North America, M'Clure found it along the west coast of Banks Island, while M'Clintock and Meham traced it along the western side of Prince Patrick Island. "The surface of the floes resembles rolling hills, some of them a hundred feet from base to summit,—aged sea ice which may be centuries old, and from want of an outlet likely to increase yet in thickness to an unlimited degree. The accumulated action of repeated thaws and falls of snow on the upper surface gives it a peculiar hill and dale appearance." The same ice was found by Nares's expedition along the northern coast of Grant Land and Greenland 80 to 100 feet thick. A branch from it flows down M'Clure Strait and M'Clintock Channel until it impinges upon the northwest coast of King William Island. This is what Professor Haughton calls "the ice barrier placed in this position by the still waters caused by the meeting of the Atlantic and Pacific tides."

The physical aspects of polar lands are much influenced by their geological formation. The Greenland coast consists mainly of gneiss, mica schist, hornblende schist, and syenite pierced by granite veins. In this formation are found the steatite used by the natives to make lamps, the cryolite of Ivigtut in the south, and the plumbago at Upernivik. North of $69^{\circ} N$, a flow of basalt extends across the Noursoak peninsula and Disco Island, covering an area of about 7000 square miles, and rising to a height of 6000 feet. With these trap rocks are associated the Miocene and Cretaceous beds. The Cretaceous rocks have only been found in the Omenak-fjord in $70^{\circ} N$; while the Miocene formation is confined to the shores of the Waigat Strait, between Disco and the mainland, underlying the trap. Coal beds appear in several places along the shore, and very interesting remains of fossil plants have been discovered. At the termination of Igalliko-fjord in $61^{\circ} N$, a compact red sandstone is found. Pendulum Islands on the east coast are Oolitic. But with these exceptions the whole mass of Greenland is granitic or gneissose. The opposite side of Baffin's Bay is of the same character, as well as both sides of Peel Sound. The Parry Islands are partly Silurian and partly of the Carboniferous period. The eastern part, including North Somerset and Prince of Wales Land (except the shores of Peel Sound) and Cornwallis Island are of Silurian formation, with fossils, equivalents to the Wenlock and Dudley groups. This formation extends westward from Boothia Felix and King William Island over Prince Albert Land and the southern half of Banks Island. The southern halves of Bathurst, Melville, and Prince Patrick Islands, and the northern half of Banks Island consist of Lower Carboniferous sandstones with beds of coal, while Grinnell Land and the northern halves of Bathurst, Melville, and Prince Patrick Islands are Carboniferous limestone. Lias fossils (ammonites) were found at one place on the east side of Prince Patrick Island in $76^{\circ} 20' N$. Sherard Osborn also found the vertebrae of a huge saurian (*Telesaurus*) at the northwest extreme of Bathurst Island, probably of the Lower and Middle Oolitic period.

Ellesmere Land, on the western side of Smith Sound, consists of gneiss rising to heights of 2000 feet which underlie Miocene rocks at Fort Poulke. Farther north the gneiss continues with stratified black slates having a very high and often vertical dip. In 82° 33' N. these slates give place to a series of quartzites and grits rising to elevations of 2000 and 3000 feet. Silurian limestones are found on the shores of Kennedy Channel up to Cape Tyron on the Greenland side. Carboniferous limestone occurs on the north coast of Grant Land, as far west as Clements Markham Inlet, rising to a height of 2000 feet. Near Lady Franklin Bay in 81° 45' N. a deposit of coal of the Miocene period was discovered, with a fossil flora including thirty species of plants—pines, birch, poplar, elm, and hazel. The whole of this land to the north of Baffin's Bay is slowly rising.

Spitzbergen and Nova Zembla are also composed mainly of primitive rocks. In northern Spitzbergen there are also Miocene beds with a fossil flora closely allied to that of Lady Franklin Bay, and some fossils of the Lias period. The geological characters of Franz-Josef Land and Spitzbergen are closely allied. The predominant rock is dolerite, a kind of greenstone.

The "tundra" of Siberia is a wide belt of land intervening between the line of forest and the polar shores, and intersected by the great rivers. It is frozen for immense depths below the surface, and here the remains of mammoths, generally in great landslips along the river banks, have been found. But their fossil ivory occurs in greatest quantity in the New Siberia group. On these islands also occur the "wood-hills," consisting of horizontal sandstone beds alternating with strata of bituminous tree stems, heaped on each other to the top of the hill. Ammonites of the Lias period are also found there.

In the polar regions the line of forest seldom reaches to Flora.

the Arctic Circle; low birches and willows and shrubs bearing berries occur in the south of Greenland, but farther north the creeping willow alone forms wood. There are 762 flowering plants, and 925 cryptogams within the Arctic Circle, making a total of 1687 plants. Lapland contains by far the richest arctic flora, amounting to three-fourths of the whole, while three-fifths of the species found in Arctic Asia and America also belong to Lapland. In the European arctic district 616 flowering plants have been collected, in Arctic Asia 233, in Arctic America eastward of the Mackenzie 379, and westward of that river 364, and in Greenland 207. The most arctic plants of general distribution, which are found far north in all the arctic areas, are three species of *Ranunculus*, a poppy (*Papaver nudicaule*), the *Draba alpina* and five other species, the *Braya alpina*, lady's-smock (*Cardamine pratensis*), eight species of saxifrage, two of *Potentilla*, two of *Arenaria*, the moss campion (*Silene acaulis*), the dandelion, a *Stellaria*, the *Dryas octopetala*, *Cerastium alpinum*, *Epilobium latifolium*, crowberry, dwarf willow, and rushes and grasses of the genera *Juncus*, *Carex*, and *Poa*. The most ubiquitous of all is the *Saxifraga oppositifolia*, which is considered the commonest and most arctic of the flowering plants.

All the arctic seas teem with the lower forms of animal life.

The invertebrate animals have been enumerated and reported upon in full detail by the naturalists to whom the collections of the various expeditions have been entrusted. The fishes, birds, and mammals of the north polar region have also been studied and carefully described within the discovered areas, though the subject is far from having been exhausted.

The human race is found to exist along the whole fringe of European, Asiatic, and American coast-line within the Arctic Circle, and to have spread up the shores of Boothia, and up both sides of Davis Strait and Baffin's Bay.

Living mainly on sea animals, the inhabitants of the polar regions rarely wander from the coast. Spitzbergen, Franz-Josef Land, and Nova Zembla are uninhabited, except that occasional summer visits are made to the southern shores of the latter group of islands. The Laps are the denizens of the European polar regions, and the Samoyeds succeed them along the shores of the Kara Sea and on the Yalmal peninsula. These Laps and Samoyeds possess herds of reindeer, and during the winter they withdraw from the coast. In Siberia there was once a coast population, but it has retired into the interior or died out, and inhabitants are not met with until the encampments of the Tchukches are reached, from the Kolyma to Behring Strait. A very complete account of this interesting people has been given by Baron Nordenskiöld in his narrative of the voyage of the "Vega." The Eskimo race extends over the whole of Arctic America and along the Greenland coasts, the warlike Indian tribes preventing them from retreating inland, and forcing them to find a precarious living or starve on the shores of the polar sea. Differing in size and physical development, the indi-

viduals of the different tribes all have flat, broad faces, black coarse hair, high cheek bones, low foreheads, short flat noses, and narrow eyes sloping upwards from the nose. Their hands and feet are small. Vast tracts of country, including the archipelago to the north of America, are not inhabited, yet there are traces of Eskimo encampments along the whole line of coast from Banks Island to Baffin's Bay. This may have been the route by which Greenland was first peopled, and it suggests a continuation of land along the same parallel, from Banks Island to the Siberian coast. Yet it may be that the wanderers found their way northwards from America by Prince of Wales Strait. The most remarkable tribe is that named Arctic Highlanders by Sir John Ross in 1818, and they are the most northern people in the world. Their stations range along the Greenland coast from 76° to 79° N., a deeply-indented coast-line of gigantic cliffs broken by deep bays, with numerous rocks and islands. They have no canoes, but dogs and good sledges, and they attack the walrus at the edge of the ice with spears. They are separated from the Eskimo of Greenland farther south by the glaciers of Melville Bay. In Danish Greenland the original Eskimo were probably intermixed in blood with the old Norse settlers, and since the time of Hans Egede the number of half-breeds has increased. In 1855 the half-breeds were calculated at 30 per cent. of the inhabitants of Greenland, and the two classes have since blended almost imperceptibly, so that there are now no full-blooded Eskimo. The population of Danish Greenland in 1870 was 9588, distributed among 176 winter stations. There are a few scattered families on the east coast of Greenland.

SOUTH POLAR REGION.

The south polar region, unlike the northern region, is almost covered by the ocean, the only extensive land being far to the south. It was of course entirely unknown to the ancients and to the early navigators of modern Europe, although a theory prevailed among geographers that a great continent existed round the south pole, the "Terra Australis Incognita." Lope Garcia de Castro, the governor of Peru, sent his nephew Alvaro Mendaña in search of it, who sailed from Callao in 1567. Another expedition under Pedro Fernandez de Quiros left Callao in 1605, and discovered land in April, 1606, which he called Australia del Espiritu Santo, now known to be one of the New Hebrides group. These were the first regular expeditions in search of the supposed southern continent.

The first ship that ever approached the Antarctic Circle was one of a fleet which sailed from Rotterdam under the command of Jacob Mahu as admiral in June, 1598. She was called the "Good News," a yacht of 150 tons, with Dirk Gerritz as her captain. She was separated from the rest of the fleet in Magellan's Strait in 1599, and was carried by tempestuous weather far to the south, discovering high land in 64° S. This appears to have been the land afterwards named the South Shetlands. Gerritz and his crew were eventually captured by the Spaniards at Valparaiso. In 1671 La Roche discovered South Georgia, a solitary island in the South Atlantic, but north even of the latitude of Cape Horn. Where so little is known, and where there is so little land, the discoveries within a few hundred miles of the Antarctic Circle come to be spoken of as south polar. In this category is Kerguelen Island in 48° 41' S., as it is at least a good base whence south polar discovery may start, though its latitude in the southern is almost the same as England in the northern hemisphere, on a meridian nearly half way between the Cape and Australia. Its discovery is due to the gallant but unfortunate Frenchman whose name it bears, Yves J. Kerguelen. He sighted it on January 17, 1772, on the same day that his countryman Marion discovered the island named after himself, on a meridian nearer the Cape. Captain Cook, in his third voyage, visited Kerguelen Island, and Robert Rhodes in 1799 mapped a considerable portion of its coast. The Sandwich group, southeast of South Georgia, was discovered in 1762.

Captain Cook in January, 1773, sailed southwards from the Cape of Good Hope in the "Resolution"

with the "Adventure" in company, and, after passing much ice, crossed the Antarctic Circle on the 17th, in longitude $39^{\circ} 35' E$. In the same afternoon they sighted thirty-eight icebergs to the southward, besides much loose ice; and in $67^{\circ} 15'$ their progress was stopped. Cook did not think it prudent to persevere in getting farther south, and bore up for New Zealand. In December, 1773, another attempt was made to discover the supposed southern continent, by steering southwards from New Zealand. On the 20th Cook again crossed the Antarctic Circle in $147^{\circ} 46' W.$, and came amongst a cluster of very large icebergs with loose ice in $67^{\circ} 5' S$. He got clear of them and after standing farther east he reached a latitude of $69^{\circ} 45' S$. in $108^{\circ} 5' W.$, and still shaping a southerly course he reached $70^{\circ} 23' S$. on January 29, 1774. Next day he came to icebergs forming an impenetrable barrier. He counted ninety-seven, which looked like a range of mountains, with closely packed ice around them. Cook's farthest point was in $71^{\circ} 15' S$. on the meridian of $106^{\circ} 54' W$. Captain Cook discovered islands in 53° to $54^{\circ} 30' S$. in January, 1775, which he named Sandwich, Willis, Pickersgill, and Georgia Isles, in about $32^{\circ} W$. In $27^{\circ} 45' W.$, he reached land which he named the Southern Thule, because it was the most southern land that had ever yet been discovered. It is in $59^{\circ} 13' S$. In the South Atlantic ice was met with as far north as 51° . In this second voyage Captain Cook made the circuit of the southern ocean in a high latitude, twice crossing the Antarctic Circle. He established the fact that, if there was any extensive south polar land, it must be south of the parallels along which he sailed. The Russian expedition under Bellingshausen in 1820 also sailed over a great many degrees of longitude in a high latitude, but only discovered two islets, Petra and Alexander. These islands were farther south than any land then known.

Auckland Island was discovered by Captain Bristow in 1806, and Campbell Island by Hazleburgh in 1810, both south of New Zealand, but far to the north of the Antarctic Circle. In 1818 Mr. William Smith of Blyth rediscovered the land known as South Shetland. His work was confirmed by Mr. Bransfield, the master of H.M.S. "Andromache," flag-ship on the west coast of South America, who further discovered another portion named Bransfield Land. Further coast-line was sighted by the French expedition under Dumont d'Urville in 1838, who named it Prince de Joinville and Louis Philippe Land.

The South Orkneys were discovered by Captain George Powell, in the sloop "Dove," on October 6, 1821. Mr. Weddell, R.N., with the sailing vessels "Jane" and "Beafoy," penetrated as far south as $74^{\circ} 15' S$. on the 20th February, 1823.

In the early part of this century Messrs. Enderby began to send vessels to the Antarctic regions for the whale fishery, which made several discoveries. The brig "Tula" of 148 tons and cutter "Lively" left London in July, 1830, under the command of Mr. John Biscoe, R.N., on a sealing voyage, but with special instructions to endeavor to make discoveries in high southern latitudes. In February, 1831, land was discovered in longitude $47^{\circ} 20' E$. and latitude $65^{\circ} 57' S$, which Biscoe named Enderby Land, in honor of his employers. He did not, however, get nearer to it than 20 or 30 miles. In February, 1831, Biscoe again discovered land in $67^{\circ} 1' S$. lat. and $71^{\circ} W$. long., to which he gave the name of Adelaide Island. It proved to be the westernmost of a chain of islands fronting a high continuous coast, since called Graham's Land. A few days afterwards Captain Biscoe succeeded in landing on Adelaide Island. In 1833 Captain Kemp, in the sealing schooner "Magpie," discovered another point of the land to the eastward, which doubtless forms part of Enderby Land.

Messrs. Enderby sent out another expedition of discovery in 1838, consisting of the "Eliza Scott" of 154 tons, commanded by Mr. John Balleny, and the "Sabrina" cutter of 54 tons, under Mr. Freeman. In February, 1839, when on about the $163d E$. meridian, they sighted high land in $66^{\circ} 30' S$. On the 12th Captain Freeman managed to get on shore, but the cliffs were perpendicular, and the valleys were filled

with ice. The discovery proved to be a group of volcanic islands, one of them rising to a beautiful peak estimated at 12,000 feet above the sea, named Freeman Peak. Sabrina Island was discovered in March, 1839. The other group received the name of the Balleny Islands. The Auckland Islands were ceded to Messrs. Enderby in 1849, and a whaling establishment was formed there under good auspices.

In 1839 the French expedition under Dumont d'Urville proceeded south from Tasmania and discovered two small islands on the Antarctic Circle named "Terre Adélie" and "Côte Clarie." At the same time Commander Wilkes of the United States expedition made a cruise to the southward and mapped a large tract of land in the latitude of the Antarctic Circle for which he claimed the discovery. But as a portion of it had already been seen by Balleny, and the rest has since been proved not to exist, the claim has not been admitted.¹

The English Antarctic Expedition of 1839-43 was undertaken mainly with a view to magnetic observations, and the determination of the position of the south magnetic pole. Two old bomb vessels, the "Erebus" and "Terror," were fitted out under the command of Captain (afterwards Sir James) Ross, with Captain Crozier in the "Terror." Dr. Joseph D. Hooker accompanied the expedition as naturalist. Leaving Chatham in September, 1839, the two vessels first proceeded to the Cape, and went thence southwards to Kerguelen Island, which was reached in May, 1840, and carefully surveyed. In August Sir James Ross established a magnetic observatory at Hobart Town. The cruise for the second season was commenced from Tasmania in November, 1840. The Auckland Islands and Campbell Island were first visited and surveyed, and on New Year's day, 1841, the Antarctic Circle was crossed about $172^{\circ} E$. A few days afterwards the two vessels were beset in the pack and began perseveringly boring through it. By January 10th they succeeded and were clear of ice in $70^{\circ} 23' S$, and next day land was sighted, rising in lofty peaks and covered with perennial snow. That day Ross passed the highest latitude reached by Cook ($71^{\circ} 15' S$). On a nearer approach to the land, there was a clear view of the chain of mountains with peaks rising to 10,000 feet, and glaciers filling the intervening valleys and projecting into the sea. The south magnetic pole was calculated to be in $76^{\circ} S$. and $145^{\circ} 20' E$, or about 500 miles southwest from the ship's position. The land interposed an insuperable obstacle to any nearer approach to it. Captain Ross landed with great difficulty, owing to the strong tide and drifting ice, on a small island near the shore, named Possession Island, in $71^{\circ} 56' S$. and $171^{\circ} 7' E$. Inconceivable myriads of penguins covered the surface, but no vegetation was seen. Next morning there was a southerly gale which moderated, and on 18th January they were again sailing south in an unexplored sea. On the 23d they were in $74^{\circ} 20' S$, and thus passed the most southern latitude previously reached (by Captain Weddell in 1823). Sailing along the newly discovered coast, Captain Ross landed after much difficulty on an island named after Sir John Franklin in $76^{\circ} 8' S$. On the 27th they came in sight of a mountain 12,400 feet above the sea, which proved to be an active volcano emitting flame and smoke in great profusion. It was named Mount Erebus, and an extinct volcano to the eastward 10,900 feet high was named Mount Terror. Along the coast as far as the eye could reach to the eastward there was a perpendicular cliff of ice from 150 to 200 feet high, perfectly level at the top, and without any fissures or promontories on its smooth seaward face. Nothing could be seen above it except the summits of a lofty range of mountains extending to the southward as far as $79^{\circ} S$. To this range the name of Parry was given. The most conspicuous headlands under Mount Erebus were named Capes Crozier and Bird. Captain Ross then sailed eastward along the marvellous wall of ice, in $77^{\circ} 47' S$. to $78^{\circ} S$. This ice barrier was calculated to be 1000 feet thick, and it was followed for a distance of 450 miles without a break. The winter was now approaching, young ice was beginning to form, but luckily a strong breeze enabled them to force their way through it. The whole of the great southern land discovered by Sir James Ross was named Victoria Land.

In returning to Hobart Town the expedition visited the Balleny Islands, and searched in vain for the land which Captain Wilkes had laid down on his chart.

In November, 1841, the "Erebus" and "Terror" again shaped a southerly course, entered the pack ice on December 18th, and once more crossed the Antarctic Circle on New Year's Day. The navigation through a belt of ice 800 miles broad was extremely perilous. At length on 1st February, 1842, a clear sea was in sight, and they proceeded to the southward in $174^{\circ} 31' W$. On the 22d they were surrounded by numerous lofty icebergs aground, and at midnight the Great Icy Barrier was sighted and its examination recom-

¹ [Yet the Royal Geographical Society of England awarded him the Founder's medal for his discoveries here.—AM. Ed.]

menced in 77° 49' S. Next day the expedition attained a latitude of 78° 11' S., by far the highest ever reached before or since.¹ After escaping imminent dangers in navigating through chains of huge icebergs Captain Ross took his ships northward, and wintered at the Falkland Islands.

In December, 1842, the expedition sailed from Port Louis on the third visit to the south polar region, seeing the first iceberg in 61° S. On the 28th the ships sighted the land named after the Prince de Joinville by Dumont D'Urville, and the southern side of the South Shetlands was discovered and surveyed. During February about 160 miles of the edge of the pack were examined, on March 11th the Antarctic Circle was recrossed for the last time, and the expedition returned to England in September, 1843. Thus after four years of most diligent work, this ably conducted and quite unparalleled voyage to the south polar regions came to an end.

In 1845 a merchant barque, the "Pagoda," was hired at the Cape, in order that magnetic observations might be completed south of the 60th parallel, between the meridians of the Cape and Australia. The ship's progress was stopped by an impenetrable pack in 68° S. The magnetic work was, however, completed.

H. M. S. "Challenger," the exploring ship commanded by Captain Nares, arrived at Kerguelen Island on the 6th January, 1874, where surveys were made, and the island was thoroughly examined by the naturalists of the expedition. Two islands, named Heard and M'Donald, were also visited, which had been discovered in November, 1853, by Captain Heard of the American ship "Oriental," owing to the practical application of the problem of great circle sailing. There is in fact a group of islands about 240 miles from Kerguelen. In February the "Challenger" ran south before a gale of wind and the first iceberg was sighted on the 11th in 60° 52' S. It was 200 feet high and about 700 long. On the 19th the ship was at the edge of a dense pack in 65° 42' S.; and on the 4th March they bore up for Australia. Several deep-sea soundings were taken, the greatest depth being 1975 fathoms. The route of the "Challenger" was much the same as that of the "Pagoda" in 1845, but more to the north. With it ends the somewhat meagre record of voyages across and towards the Antarctic Circle.

(C. E. M.)

POLE, REGINALD (1500-1558), generally known as Cardinal Pole, was born at Stourton Castle, Staffordshire, March 3, 1500. He was the son of Sir Richard Pole and Margaret, countess of Salisbury. Designed from early youth for the church, he was educated in the Carthusian monastery at Sheen, and at Magdalen College, Oxford. He was admitted to deacon's orders at the age of sixteen, and at once received high preferment, holding, among other benefices, the deanery of Exeter. He continued his studies at the university of Padua, where he made acquaintance with Erasmus and other prominent men, and after a visit to Rome in 1525, returned to England. Henry VIII. was eager to keep him at court, but Pole appears to have held aloof from politics until the question of the king's divorce drew him from his retirement. He was probably from the first opposed to Henry's policy, but we find him, nevertheless, in 1530, at Paris, charged with the duty of obtaining the decision of the Sorbonne on the question at issue. That decision given, he returned to England, but refused to approve the king's divorce, or the other measures connected with it. The king, anxious to gain his adhesion, offered him the archbishopric of York, vacant by the death of Wolsey in 1531. After some hesitation, he refused the offer and left the country.

This was the turning-point in his career, and concludes the first of the three periods into which his life may be divided. During the second period, for upwards of twenty years, he lived abroad, the declared and active enemy of the Protestant movement in his own country. After passing a year at Avignon, he took up his residence a second time at Padua. As he had not yet declared himself publicly against Henry, the latter continued favorably disposed towards him, allowing him the revenues of his deanery, and exempting him from the oath of allegiance to Queen Anne's children. In 1535, however, there came a change. The king sent to ask his formal opinion on the divorce and the ecclesiastical supremacy. Pole's answer, afterwards published, with considerable additions, under the title *Pro Unitate Ecclesie*, was sent to England early in the next year. It contained a vigorous attack upon Henry's policy and menaced the king with condign punishment at the hands of the emperor and the king of France if he did not return to his allegiance to Rome. Summoned to England to explain himself, he refused to come. Late in 1536 he was made cardinal, and early next year he was sent as papal legate with the object of uniting Charles V. and Francis I. in an attack upon England, which was to coincide with a

rising of the Romanists in that country. The terms of peace between England and France making it impossible for him to remain in the latter country (for he was now attainted of high treason), he passed into Flanders, and soon afterwards (August, 1537) returned to Rome. A year later (November, 1538) he published his book, together with an apology for his own conduct, addressed to Charles V. In 1539, after the bull of excommunication had been issued against Henry VIII., Pole went to Spain in order to urge Charles to attack England. An invasion was threatened but given up, and Pole retired to Carpentras. From 1539 to 1542 he acted as papal legate at Viterbo. In 1543 he was contemplating an expedition to Scotland with an armed force to aid the anti-English party, and in 1545 he was corresponding with the same party and with Charles V. for a joint attack on England. In the same year he went to Trent in disguise, to avoid the danger of seizure on the way, and presided at some of the preliminary meetings of the council. On the death of Henry VIII. he made an attempt to reconcile himself with the English government, but in vain. In 1549 he was a candidate for the papacy on the death of Paul III., and at one moment was on the point of being elected, but in the end was unsuccessful, and retired to Maguzzano, on the Lake of Garda. When Edward VI. died Pole was engaged in editing his book *Pro Unitate Ecclesie*, with an intended dedication to that king.

The accession of Mary opens the third period of his life. The pope at once appointed him legate, and entered into negotiations with the queen. A marriage between her and Pole was at one moment contemplated, but the state of public feeling in England rendered his return impossible, and he was kept waiting for a year in Flanders and Germany. The reaction at length produced a parliament favorable to Rome, and enabled him to return (November, 1554). As legate he received the national submission, and pronounced the absolution, accepting at the same time, on behalf of the pope, the demands of parliament with respect to ecclesiastical lands, etc. Next year he was on two occasions a candidate for the papacy, but was twice disappointed. After Philip's departure, and the death of Gardiner (October, 1555), Pole became Mary's chief adviser, and, with her, must bear the blame of the persecution which followed on the reunion with Rome. On Crammer's death (March, 1556) he became archbishop of Canterbury, but soon afterwards (May, 1557) fell into disgrace with the pope, Paul IV., who was his personal enemy. On the outbreak of the war with France, Paul, the political ally of that country, cancelled Pole's legatine powers and even charged him with heresy. No remonstrances on the part of Mary and Pole himself could induce the pope to retract this sentence, and Pole died (Novem-

¹ [This expedition proceeded southward 1st February in 158° 12' W. and reached 78° 11' in 161° 27' W. See Ross's *Voyage of Discovery and Research in Southern and Antarctic Regions*, 1839-43, vol. ii. p. 187-201. London, 1847.—AM. ED.]

ber 18, 1558) at enmity with the power in whose support he had spent his life.

His chief works are *Pro Unitate Ecclesie, ad Henricum VIII.* (ed. princ., Rome, n. d.); *Reformatio Anglie* (Rome, 1556); *De Concilio* (Rome, 1562); *De summi Pontificis officio et potestate* (Louvain, 1569); *De Justificatione* (Louvain, 1569); *Letters, etc.*, (ed. Quirini, Brescia, 1744).

POLECAT. This name is applied to one of the English members of the large Family *Mustelidae*, which contains besides the Martens, Weasels, and Badgers (see *MAMMALIA*, vol. xv. p. 446, and the separate articles under these names).

In this family the Polecats, while belonging, with the stoats, weasels, and many others, to the nearly cosmopolitan genus *Putorius*, form by themselves a

Common Polecat.

small group confined to the northern hemisphere, and consisting of four species, of which the best known and most widely distributed is the common polecat of Europe (*Putorius feticus*). This animal, at least so far as its disposition, size, and proportions are concerned, is well known in its domesticated condition as the ferret, which is but a tamed albino variety of the true polecat. The color of the latter, however, instead of the familiar yellowish white of the ferret is of a dark brown tint above, and black below, the face being variegated with dark brown and white markings. Its skull is rough, strongly ridged, and altogether of a far more powerful type than those of the stoats, weasels, or martens; the skull of the female is very much smaller and lighter than that of the male. Its fur is long, coarse, and of comparatively small value, and changes its color very little, if at all, at the different seasons of the year.

The distribution and habits of the common polecat have been well described by Blasius in his *Säugethiere Deutschlands*, and the following is an abstract of his account. The polecat ranges over the greater part of Europe, reaching northwards into southern Sweden, and in Russia to the region of the White Sea. It does not occur in the extreme south, but is common everywhere throughout central Europe. In the Alps it ranges far above the tree-line during the summer, but retreats in winter to lower ground. In fine weather it lives either in the open air, in holes, fox-earths, rabbit-warrens, under rocks, or in woodstacks; while in winter it seeks the protection of deserted buildings, barns, or stables. During the day it sleeps in its hiding place, sallying forth at night to plunder dovecots and hen-houses. It climbs but little, and shows far less ac-

tivity than the marten. It feeds ordinarily on small mammals, such as rabbits, hamsters, rats, and mice, on such birds as it can catch, especially poultry and pigeons, and also on snakes, lizards, frogs, fish, and eggs. Its prey is devoured only in its lair, but, even though it can carry away but a single victim, it commonly kills everything that comes in its way, often destroying all the inhabitants of a hen-house in order to gratify its passion for slaughter. The pairing time is towards the end of the winter, and the young, from three to eight in number, are born in April or May, after a period of gestation of about two months. The young, if taken early, may be easily trained, like ferrets, for rabbit-catching. The polecat is very tenacious of life and will bear many severe wounds before succumbing; it is also said to receive with impunity the bite of the adder. Its fetid smell has become proverbial. To this it is indebted for its generic name *Putorius* (derived, as are also the low Latin *putatus*, the French *putois*, and the Italian *puzzola*, from *puteo*), as well as the designation *foumart* (i. e. foul marten), and its other English names *fichet*, *fitchew*. Attempts to account for the first syllable of the word *polecat* rest entirely on conjecture.

The other species of the polecat group are the following:

The Siberian Polecat (*Putorius evermanni*), very like the European in size, color, and proportions, but with head and back both nearly or quite white, and skull more heavily built and sharply constricted behind the orbits, at least in fully adult individuals. It inhabits the greater part of southwestern Siberia, extending from Tibet into the steppes of southeastern European Russia.

The Black-footed or American Polecat (*Putorius nigripes*), a native of the central plateau of the United States, and extending southwards into Texas. It is very closely allied to the last species, but has nevertheless been made the type of a special sub-genus named *Cynomys*, or "King of the Prairie Marmots," a name which expresses its habit of living in the burrows of, and feeding upon, the curious prairie marmots (*Cynomys*) of the United States. An excellent account of this species may be found in Dr. Elliott Cones's *Fur-bearing Animals of North America*.

Lastly, the Mottled Polecat (*Putorius sarmaticus*), a rare and peculiar species occurring in southern Russia and southwestern Asia, extending from eastern Poland to Afghanistan. It differs from the other polecats both by its smaller size and its remarkable coloration, the whole of its upper parts being marbled with large irregular reddish spots on a white ground, and its underside, limbs, and tail being deep shining black. Its habits, which seem to be very much those of the common polecat, have been studied in Kandahar by Captain Thomas Hutton, who has given a vivid description of them in the *Journal of the Asiatic Society of Bengal* for 1845.

POLEVOY. SEE RUSSIAN LITERATURE.

POLICE. The branch of criminal justice which comprises a methodical system for the prevention and detection of crime is commonly known by the name of "Police." With the system having these objects is combined the execution of many duties not strictly involved in the popular definition of crime, but materially affecting the security and convenience of the public. Bentham, more comprehensively, says that police is in general a system of precaution either for the prevention of crime or of calamities. It is destined to prevent evils and provide benefits. The system for the attainment of these objects and the introduction and establishment of that system in the United Kingdom form the main subject of this article; some account will afterwards be given of the police in other states.

In this view the definition and use of the word "police," as meaning the regulation and government of the city and country in relation to the inhabitants, are not sufficiently close. When Blackstone says that by the public police and economy he means "the due regulation and domestic order of the kingdom, whereby the individuals of the state, like members of a well governed family, are bound to conform their general behavior to the rules of propriety, good neighborhood,

and good manners, and to be decent, industrious, and inoffensive in their respective stations," the definition is capable of an interpretation at once too wide and too narrow for the present purpose. It is vain to look for an accurate description of police, as a system, in writers of a period when the thing sought for had no existence. The system is of recent growth, and it is necessarily more associated with personal instruments for the attainment of objects than with the objects to be attained. An observation of Gibbon, referring to the *ædiles* and *quæstors* of the Roman empire, that officers of the police or revenue easily adapt themselves to any form of government, correctly presents the idea of distinctive personal elements. A system of police administration includes neither the making of the law nor the law itself. Officers of police are neither legislators nor (in the usual sense) magistrates. They are the instruments by which conformity to the rules of the commonwealth is attained.

Apart from the repression of crime as generally understood, it is plain that, at least in crowded cities, a power ought to exist for the suppression of noise and disorder, the regulation of locomotion and traffic, the correction of indecency, and the prevention of a numerous class of annoyances and impositions which can only be restrained by cognizance being taken of them at the instant. To these may be added a number of petty disputes the immediate settlement of which tends materially to the public peace. Over such subjects as these it is obviously for the general advantage the police should have a summary control. Any apprehension of danger to liberty can only be founded on its abuse and not upon its proper exercise.

The employment of persons in these various duties, as well as in the prevention and detection of graver matters of crime, constitutes a division of state labor. Therefore, while it is perfectly correct to speak of the various legislative and other measures for good order as "matters of police," the organization and management of the police forces constitute a distinct subject.

The essential features of the established police system, alike in Great Britain and in foreign states, in cities and towns as in countries and village communities, comprise the following matters:

I. A body of persons in relation to the state enforcing obedience to the criminal law, the prevention and detection of crime, and the preservation of order, over a defined area, generally divided and subdivided for the purpose of distribution and immediate government of the force, but having one jurisdiction throughout.

II. The division of that force into classes of various rank, comprising, in general, in ascending order, constables, sergeants, inspectors, and superintendents (or their equivalents),—the constables being the most numerous and themselves divided into classes.

III. General control of the entire body by heads, whether styled commissioners or chiefs, having power to make regulations for the government of the force, subject in turn to the control of state authorities.

IV. Patrol day and night of the streets, roads, and public places,—the "beats" and "tours of duty" of constables being prescribed by regulations, and actual performance and compliance being secured by the sergeants and inspectors.

V. The payment of the force, including establishment charges, out of public funds provided for the purpose.

In dealing with these subjects as nearly as may be in the order indicated, the relationship of the police force to the state is of primary importance. A general control by the executive Government of a state of the police forces, for the legitimate objects for which they are established, seems essential. In Great Britain every member of the force, from an ordinary constable upwards, stands in the direct position of a servant of the crown. On admission he makes a promissory declaration (recently substituted for an oath) that he will serve the sover-

ein; and it is upon the fact that a police constable has the powers, duties, and privileges of a peace officer of and for the crown that many of the incidents of his service depend, although the immediate power of dismissal is vested in heads of a force, whose orders he is bound to obey.

The state employs the police forces for the public welfare only. "There is not in England," remarked the late Chief-Justice Cockburn, "any more than in America, any system of espionage or secret police to pry into men's secret actions or to obtain information for the Government by underhand and unworthy means." The truth of this is exemplified in the present position of police administration in the metropolitan police district of England acting under the immediate control of the secretary of state. The fear expressed, and no doubt felt, on the first establishment of a regularly organized system of police, that the freedom of holding meetings and the utterance of opinion at them would be suppressed, has been dispelled. The police are expressly enjoined not to interfere with persons attending political meetings unless specially ordered, and such orders are not given unless disorder or a breach of the peace is imminent. Public addresses, even in some of the royal parks, are permitted, provided they do not cause any obstruction, and are not of an unlawful character. There are no Government police to watch the delivery of mere political opinion or the tenor of its reception by the auditory. The press is also free from Government interference, through the police, in matters short of crime or not directly incentive to crime.

The sphere of action of the police force in relation to the state has been extended by legislative enactments providing that criminals who have escaped to or from colonies may be followed and removed by process of law, and tried where the crime originated. The practical execution of the law as to these fugitive offenders rests with the police. The same observation applies to the province of police under extradition treaties. But the general action of the police force of a country is bounded by its shores. As the open sea is not the territory of any one nation, it is not competent to any one nation to preserve order or remove all delinquents on its surface, as it is in the ports, rivers, and lakes of a state. When Lord Castlereagh at the congress of Vienna spoke of the "police" to be exercised over ships carrying slaves, Talleyrand asked the precise meaning of the expression; and, on the English statesman explaining that he intended to refer to what every Government exercised in virtue of its sovereignty or under treaties with other powers, Talleyrand would not admit the existence of any maritime police, except that of each power over its own vessels.

The supervision of the police by the Government stands thus: The commissioner of police of the metropolis of London is appointed by and acts under the immediate direction of the secretary of state for the home department. The commissioner of police of the city of London is in communication with the corporation, who appoint him. There is, however, a power of approval of regulations in the secretary of state. In the counties of England the appointment of the chief constable is by the county magistrates subject to the approval of the secretary of state. In municipal corporations the police, including the chief or head constable, are appointed by the watch committee. In all these cases except in the metropolis the secretary of state leaves the immediate control to local authorities and disclaims responsibility. In Scotland the secretary of state has a voice in the rules for the government, pay, and necessities of the force. The appointment of the chief constable is subject to his approval, but practically there is no interference called for in this respect. In Ireland great authority is vested in the lord lieutenant both with respect to the police of Dublin and

Relation to
the state.

Government
supervision.

the royal Irish constabulary. The immediate government is vested in the heads of the forces, and the parliamentary responsibility is in the chief secretary for Ireland. Reports and returns as to the police forces of Great Britain and Ireland are laid before parliament. The immediate control and responsibility of a cabinet minister for the police of the metropolis of London makes a very important distinction between the position of that force and of the other police forces of the empire. There is, however, a general relationship of the police forces of the country to the state, arising from the contribution (not now limited to a particular proportion) made by parliament to the expenditure for a police force. Under an Act of 1856 the crown appoints three persons as paid inspectors to visit and inquire into the state and efficiency of the police appointed for every county and borough in England and Wales, and to see whether the provisions of the Acts under which they are appointed are duly observed and carried into effect; and upon the secretary of state's certificate of efficiency, laid before parliament, the contribution is made. In the same way an inspector for Scotland reports annually.

It is to be observed that the contribution cannot be made to a borough police not consolidated with the county police where the population is less than 5000. In England the state, except in the city of London, contributes about half the pay of forces which submit to certain regulations, to inspection, and to a definite amount of imperial control. In Scotland the state also contributes. About two-thirds of the cost of the Dublin metropolitan police is met by the treasury. The balance in all the above cases comes from the locality. The royal Irish constabulary is the only force whose ordinary strength is entirely supported by imperial taxation, subject, however, to payment by districts where special services are necessary.

To prevent political influence being brought to bear upon the police, they cannot vote at elections of members of parliament within their district; and the chief officers are disqualified from sitting in parliament.

The relationship of the police forces of the country to the army as a state force is satisfactory. The police is a civil force. Although constables constantly speak of the public as "civilians," the police are in turn styled civilians by soldiers. It is now only on rare occasions that soldiers are required to intervene in the case of riot or tumult, as fortunately the police force is generally sufficient for the preservation of the peace of the country. If disturbance is apprehended in any district, special constables are called upon to aid. It is no less due to the improved temper and habits of the people than to the existence of the police force that military display is rarely needed to suppress riots. In state processions and on some other occasions the police and household troops together maintain the line of route, and where troops assemble for inspection the police sometimes aid in keeping the ground. The police, as constables, are required to carry out the law as to billeting and the impressment of carriages,—at one time a very heavy incident of duty, but considerably lightened by the practice of conveying troops by railway. The police apprehend deserters on reasonable suspicion. Police in charge of a station must receive prisoners, including deserters and absentees subject to military law, if duly sent there by military authority; and, as a person subject to military law is usually left to be dealt with by the ordinary civil tribunal for offences, he is taken by the police before a magistrate. On the other hand no person subject to military law, whether an officer or a private, can neglect or refuse to deliver over to the civil magistrate any officer or soldier accused of an offence punishable in the ordinary mode, or to assist the police in his lawful apprehension; an adjustment of military and civil law is therefore effected.

The duties devolving on a police force require a fuller notice than the general remarks already made.

A constable on ordinary patrol duty has to attend to every circumstance that a keen eye and ready ear bring under his notice. In a carefully drawn statute, although not now in general use, the general sphere of observation and duty by constables is thus summarized:

General duties.

"During the time they shall be on duty, use their utmost endeavors to prevent any mischief by fire and also to prevent all robberies, burglaries and other felonies and misdemeanors and other outrages, disorders and breaches of the peace and to apprehend and secure all felons, rogues, vagabonds and disorderly persons who shall disturb the public peace, or any party or persons wandering, secreting or misbehaving himself, herself or themselves, or whom they shall have reasonable cause to suspect of any evil designs, and to secure and keep in safe custody any such person, in order that he or she may be conveyed as soon as conveniently may be before a justice of the peace, to be examined and dealt with according to law: and it shall and may be lawful to and for the said watchmen, sergeants of the watch, patrols and other person or persons to call and require any person or persons to aid and assist them in taking such felons, rogues, vagabonds and all disorderly or suspected persons as aforesaid." (3 & 4 Will. IV. c. 90, § 41).

Police action in relation to the serious matters constituting crime is familiar knowledge. It is essential to bear in mind that the powers of the police in arresting and otherwise dealing with criminals in a variety of ways is derived from and depends on police constables having been expressly invested with the powers and duties of the old parish constables. Every police force has been given these powers and duties of constables, and the possession of them is so essential that, however they may be supplemented by modern legislation, without them no police force could exist for a day.

Relation to crime.

A statistical or other inquiry into crime is necessarily beyond the limits of this article. A few facts, however, bear on the efficiency of the police forces.

The returns indicate that the apprehensions in 1881-82 were (omitting fractions) in the proportion of 41 per cent. to the number of crimes committed in England and Wales, against a like proportion in 1880-81, 42 per cent. in 1879-80, 45 in 1878-79, 44 in 1877-78, 46 for 1876-77 and 47 per cent. for 1875-76.

The director of criminal investigations reported for the year 1882 that a comparison of the statistics—which are prepared by an independent service with a scrupulous regard to accuracy—with those of foreign cities shows that the metropolis of London (metropolitan police district), with a territory nearly 700 square miles in extent, covered by more than 700,000 separate houses and inhabited by a population barely less than 5,000,000, is the safest capital for life and property in the world.

Although criminal procedure does not admit of being fully treated here as part of the police system, yet as the police by duty as well as practice are in fact prosecutors in the majority of criminal cases, the important part taken by the police force requires notice.

The efficiency of the police, as well as the exigencies of cases, has led to the arrest of offenders or suspected persons in the great majority of felonies and other crimes, where the power exists, without applying to magistrates for warrants in the first instance. Although there are some advantages attendant upon a practice under which magistrates do not hear of the matter until the accused is actually before them, it is undoubtedly better, as recently declared by the commissioners reporting on the criminal code, for the police officer to obtain a warrant where circumstances admit of his doing so. When he arrests, whether with or without a warrant, it is his duty to take the prisoner before a magistrate.

Without attempting to enter fully into the rights and duties of the police in relation to arrest, it may be mentioned that, while the important action of the police is derived from and wholly dependent (except in some cases where recent legislation has found a place) on the older powers, science has been made subservient in facilitating the application of those powers to police duties. As in old times the reasonable suspicion giving the right to arrest may still be founded on personal observation and information in the

Connection with the army.

ordinary mode, but the electric telegraph and the photograph now lend their aid as recognized agents in favor of justice and truth far more than in aid of fraud and deception.

If an arrest is without a warrant, it is the officer's duty to show that he acted rightly by establishing at least that he proceeded on reasonable information. His task is generally much more. He or some police officer, whether acting under a warrant or not, has to adduce all the evidence to justify a committal for trial, or, if the case is one in which the court of summary jurisdiction has the power, for a conviction. In carrying out this duty even in simple cases a multitude of matters have to be attended to in which a number of police officers take a part. Whether the arrest is made by a constable on his beat or under other circumstances, the ordinary duty involves taking the prisoner to the police station, where the charge is entered. He is then taken before the magistrate, or, in some cases, bailed. If the charge be one of felony it generally involves a remand, not only for the attendance of witnesses, but to ascertain the prisoner's antecedents, and these remands are often multiplied in complicated cases. Every remand involves the conveyance of the prisoner to and from the prison or "lock-up"—generally the former. Detective police attend at the prison to ascertain whether the accused has been previously convicted or charged. Witnesses must be seen and their attendance secured. If the prisoner is eventually committed for trial it is the duty of the inspector or other officer having charge of the case to aid the magistrate's clerk in making out the certificate of costs, so that the proper amounts for the allowance of witnesses are inserted. Although in ordinary cases there is a nominal "prosecutor" (the person who has been wounded or lost his property), if he enters into a recognizance before the magistrate, he leaves everything to the police, who have to inform him even when and where he must attend for the trial, and the police are required in many cases to give the necessary instructions for the indictment, and when the proper time arrives for the trial at the sessions or assizes (of which public notice is given), the police must inform the witnesses and arrange for their conveyance and prompt attendance in the precincts of the court, first before the grand jury, afterwards on the trial. A police officer must attend the taxing officer, give the necessary particulars as to the witnesses and see that they receive their allowances.

The responsibilities and duties of the police may be varied, but on the whole are scarcely diminished, if there is a solicitor for a private or for the public prosecutor; the Act of 1884 relating to the public prosecutor regards the police as essential parties, and it is certain that no general system of prosecution can be carried on with diminished police intervention.

The duties of police to accused persons are too important to be passed over in complete silence. To say that they involve perfect fairness ought to be a sufficient guide, but it is right to add that the indirect as well as the direct extortion of statements, either by threat or promise, is forbidden. On the other hand, to caution accused persons is not the province of the police, as on the one hand a police officer ought not in general to put questions, so on the other hand he ought not to prevent voluntary statements. His general duty is to listen and to remember accurately what the accused says. It is often the duty of an officer to give information to the accused, as for instance of the nature of the charge on which he is arrested or to read the warrant, but information of this kind should not be given interrogatively. It sometimes happens, however, that in the course of inquiries a person makes a criminatory statement to a police officer, in consequence of which it is the duty of the officer to arrest him. This is distinct from questioning a person whom the officer has not merely suspected but predetermined to arrest.

Some other duties, the growth of modern times and unknown until recently, devolve on the police in relation to criminals. They arise from the release of offenders sentenced to penal servitude before the expiration of the period, on certain conditions, or of offenders sentenced, after the expiration of their sentence of imprisonment, to be under police supervision for a given period. Both classes of convicts involve the performance by the police of very responsible duties in reference to reporting and giving notice of changes of residence, so as to make the watch and supervision a real thing, and at the same time to give the convicts the opportunity, as intended, of gaining an honest livelihood at some labor or calling. It is a frequent source of complaint by the convicts that they are so watched that they cannot obtain employment, and are driven into the repetition of crime,—the police retorting that the allegations are untrue, and that the fresh offence is the result of

the habitual offender's incurable love for crime. Any constable in any police district may, if authorized so to do (in writing) by the chief officer of police of that district, without warrant take into custody any convict who is the holder of a license if it appears to such constable that such convict is getting his livelihood by dishonest means, and may bring him before a court of summary jurisdiction. The system of "reporting" is itself a branch of police administration of great importance, and requiring considerable knowledge. Its headquarters may be said to be in the metropolis and under the superintendence of the police of that district, but it involves constant communication with other districts and observation throughout the kingdom.

The extent of police duty in respect of such offenders is shown by the fact that, according to the last published return, there were in England and Wales 1268 convicts on license and persons under sentence of supervision.

The police are in general the instruments for carrying out the statutory provisions respecting certified industrial schools and reformatories. Not only is the process for the most part directed to the police, but magistrates and others interested look to the force for suggestions and assistance. In some respects it would be desirable if industrial schools, as distinguished from reformatories, could be worked without the intervention of police agency, but that seems impracticable.

An important police function relates to the execution of process, and is not confined to subjects or cases in which the force is collectively or individually concerned in the performance of their duty. Whether the process is a warrant or a summons, its execution or service is in the hands of the police. Magisterial warrants of apprehension and search are by law, in other than exceptional cases, necessarily directed to the police as peace officers, whether their purport be to bring the person before the tribunal or to convey him from it or from one place to another; and in other warrants of execution, although parochial officers are often joined, police are also included to prevent abuses of the law to which the poor are so much exposed. Police officers are now expressly required to have the direction of warrants of distress. The service of a magisterial summons, although not in general prescribed to be effected by a police officer, in practice properly devolves on the force. In the metropolitan police district all police service must be by its officers. In a great variety of matters where notice has to be given to persons, the duty of communicating it either verbally or in writing or in print is thrown on the police. So convenient a medium for the orderly administration of purely civil matters are the police found that, at the request of the local government board, the police are allowed to deliver and collect voting papers in the election of parochial officers.

The increased area over which a police constable as compared with the old parish constable has jurisdiction facilitates both arrests and service of process. Although stationed within a defined area of limited jurisdiction, the duties of the force often involve the operation of functions without geographical limits, requiring the actual presence of its members outside as well as the performance within the district of much that relates to the exterior.

The service of process calls for constant communication between different police forces. The law provides for the backing of warrants, by which a constable can act beyond his ordinary jurisdiction or by which the warrants can be transmitted. A magisterial summons for appearance does not require formal transmission. It is addressed not to the police but to the defendant, and can be served by an officer of any district; but, as until recently the proof of service could only be given by the personal attendance of the serving officer at the magistrate's court, great expense was incurred in travelling to effect service, and inconvenience in attending to prove it. This has been remedied in most cases by allowing service to be proved by a declaration before a magistrate.

The transmission of process, declarations of service, payment of fees, and many other incidents arising in apparently the most simple cases now involve constant communication between police forces by whatever distance they may be separated.

A few lines must suffice on the general duties of the police force in relation to a variety of other matters. Some of these are closely connected with crime, others with municipal regulations only. The police, as having all the duties of constables, act as coroner's officers; they make minute inquiries as to suicides, accidents of every kind, insane persons and their apprehension, and deal with destitute persons and persons seized with sudden illness in the streets, and with vagrants.

Relation to reformatories.

Execution of process.

Miscellaneous duties.

In populous districts the adjustment of street traffic, of securing the comfort as well as safety of persons in passing to and fro, whether on foot or otherwise, forms a very important branch of the constable's duty. This may be and often is effected by the mere presence of the constable passing on his round without greater exercise of his authority than a request to persons to move or to wait at crossings. Unless in crowded parts, this highway branch of duty may consist in preventing riding and driving furiously, or on footpaths. The general or local laws of each district give ample scope for the exercise of the police constable's authority and the performance of his duties in such matters, including obstructions of all kinds.

In the metropolitan police district the commissioner has large powers, including the power to prescribe special limits in the metropolis within which some acts affecting the general ease and freedom of the public are forbidden which are innocent elsewhere.

On the police almost invariably devolve the licensing of public carriages and the enforcement of the great variety of regulations respecting them. In the metropolitan police district the licensing of public carriages is vested in the secretary of state, who makes numerous regulations respecting the carriages and their drivers and proprietors, and gives (under power vested in him by the legislature for that purpose) the administration of this important branch of the law to the commissioner of police. Elsewhere in England and Wales the administration of the law in relation to hackney carriages is in the hands of local authorities. The police have charge of the maintenance of good order in houses and

places licensed for the sale of intoxicating liquors, including inquiries and notices as to all kinds of licenses, renewals, and transfers, and of course involving the conduct of numerous persons, not only of the licensed persons and those in their service, but of persons frequenting their houses, not excepting the members of the police force.

The laws and regulations for common lodging-houses in the metropolis are under the police. Other traders exercise their constant vigilance, including pawnbrokers, marine store dealers, pedlars, and chimney-sweepers.

Among almost an infinity of offences may be enumerated those involving cruelty to animals, prize fights so called, and all descriptions of unlawful brawls (including brawling in places of public worship), gaming, gambling, and betting, lotteries, disorderly houses, dangerous performances, the infraction of fence months and seasons for birds and fish, the fraudulent removal of goods, violations of cattle plague orders (which the police are expressly required to observe and enforce, involving of late years most arduous duties), and the sale of unwholesome food and of poisons. The police have also to deal with the care and keeping of explosive substances, animals straying, and dogs reasonably suspected to be mad or not under proper care.

Some public offences, such as the use of inaccurate weights, adulteration of articles of food, etc., are generally dealt with by inspectors and other special officers, although it is undoubtedly the duty of the police to aid in enforcing the law, and to report to the proper quarter offences coming to their knowledge. In the metropolis smoke nuisances are dealt with as police offences.

The police aid the inland revenue in a variety of ways, and, although it is generally undesirable for the police to take part in the collection or enforcement of taxation, they are required in the metropolitan district, by order of the secretary of state, to enforce as far as lies in their power the payment of the dog tax, their other duties giving them greater knowledge on the subject.

In visiting places of amusement the police are often performing duties of a multifarious character. In general the one object is the maintenance of good order, but sometimes the observation extends to the character of the amusement and the infringement of licenses.

Apart from the special duties as to the restoration of property left or lost in public carriages, or with reference to prisoners' property, for which there are special provisions, the police exercise a reasonable rather than a specially assigned duty in facilitating the recovery of lost and stray property by the rightful owners.

A very few words must suffice for notice of a subject which has been a vexed question before as well as since the establishment of a police force in the country, and down to the present moment

—the action of police powers as to street prostitutes. Practically this action has nearly the same limits throughout England and Wales. In the metropolitan police district and in the City of London it is an offence for a common prostitute or night-walker to loiter or to be in a public place for the purpose of prostitution or solicitation to the annoyance of the inhabitants or passengers. Elsewhere the offence is in much the same terms included in the Police of Towns' Clauses' Act, 1847, and is so applied to all urban authorities under the Public Health Act, 1875. In the practical application of the law it is generally considered that there must be some evidence of a personal annoyance by and to one or more persons to justify a conviction.

The preceding survey of some of the multifarious functions of a police force affords an illustration of Bentham's classification of the business of police into distinct branches: police for the prevention of offences; police for the prevention of calamities; police for the prevention of endemic diseases; police of charity; police of interior communications; police of public amusements, police for recent intelligence and information. No attempt, however, is made in the present article to follow such classification. It would lead the reader astray, where the object is to treat principally of the police force.

As to the defined area of police action, for general purposes the legal rights and powers of a police force (subject to the observations already made) are coextensive with the police district. In the metropolitan police district the members of the force have the powers of constables in the adjoining counties (10 Geo. IV. c. 44, § 4; 2 & 3 Vict. c. 47, § 5).

The determination of the geographical area of a police district is necessarily governed by a variety of circumstances. Physical features have sometimes to be taken into account as affecting the demarcations of intercourse, more frequently the occupations of the people and the amount of the population. A district may be too confined or too large for police purposes. The limited ideas of simple-minded rustics of a former generation whose views of complete independence consisted in inhabiting two adjacent rooms in different parishes, so as to effectually baffle the visits of parochial officers, is probably a notion of the past; but obstructions of a like kind may arise from too narrow boundaries. On the other hand dense populations or long-accustomed limits may outweigh convenience arising from a wide area.

In any case the making of altogether new boundaries merely for police purposes is very undesirable. The county, or divisions of a county or city, or the combination of parishes, ought to be and are sufficient for determining the boundaries of a police district. A boundary, moreover, that does not admit of ready application for rating is impracticable.

In England, Wales and Scotland, with the exception of the metropolitan police district and the area of the City of London (geographically included within but distinct from it in police government), the police districts are for the most part identical in area with the counties. Large towns have police forces distinct from the county force surrounding them. There are 290 police forces in the island,—a number liable to frequent variation, as separate forces are created or existing forces are combined, for which powers exist.

By far the largest and most important force, as regards the character of both area and numbers, is that of the metropolitan police district, comprising 20 divisions. The total number of the police (including of course the county constabulary) for England and Wales for the year ending 29th September, 1883, was 34,448, an increase on the previous year of 1315. During the last decade the increase in the total number of the police, allowing for the augmented population, is trifling.

The following are the numbers composing the different forces in 1882-83:

In boroughs under the Municipal Corporation Act	
and under local Acts.....	9,685
In counties.....	11,255

Metropolitan police constables, including royal dock-yards.....	12,663
City of London.....	885

Total.....34,488

The total gives one constable for every 774 of the population, according to the census of 1881. In boroughs, etc., there is 1 for every 758; in counties 1 for 1231; in the metropolitan police district (deducting 807, the number employed in royal dockyards, and 446 paid for by public companies and private individuals) 1 for every 413; and in the City of London 1 for every 57 of the City population, as enumerated on the night of the census of 1881. The total number, exclusive of the commissioner and assistant commissioners, belonging to the metropolitan police force on the 1st January, 1884, was 12,404,—comprising 10,741 constables, 1028 sergeants, 608 inspectors, 24 divisional superintendents, 1 chief superintendent (of the criminal investigation department), and 2 district superintendents.

The strength of the police force in proportion to population varies considerably in each county of Scotland, ranging for the year ended 15th March, 1884, from 1 in 731 in Selkirk to 1 in 2438 in Banff. In burghs it varies from 1 in 532 in Edinburgh and 1 in 535 in Glasgow to only 1 in upwards of 1500 of the population in the smallest burghs.

The strength of the royal Irish constabulary on the 1st July, 1882, the geographical area of which comprises all Ireland, consisted of 258 officers and 13,750 men, and it was subsequently increased to 14,601 of all ranks.

The equal distribution of the force throughout a district—not a uniform distribution either as to area or population, but equal in accordance with wants—is one of the greatest difficulties in the administration of a police force. It is not merely that recruits must be sought for to keep pace with increase or variations of population, but daily and hourly events necessitate daily and hourly changes of distribution. The duty is not merely to draw off men from adjacent divisions to the spot for a few hours, where they can be best spared, but to fill places where required. It must be remembered that extra work by day incapacitates men for the night watch, and it takes days to restore the equilibrium. It is needless to say that, although the services of the police force may not be required to aid in the extinction of a fire, their presence is required in great numbers to preserve order; and thus men are necessarily kept on duty beyond their prescribed hours. Nor, in many of these cases, whether seen or unforeseen, is the distribution of the force self-adjusting. Let all do what they may in aid through all ranks of the force, inequalities must occur; and before the gaps are made up a fresh displacement occurs. Much may be done and is done by a system of reserves, and by averaging the yearly extra calls on the time of a force; but after all there is no perfect equality. The peacefully slumbering citizen may be startled by the announcement that, although the force of the metropolitan police district has been under anxious management for upwards of half a century, on no two nights since its formation have the beats been patrolled to precisely the same extent.

The police system of necessity involves the existence in a district of police stations or lock-ups, Stations. for the temporary detention of prisoners; and magistrates have generally the power to remand prisoners to these for short periods. Power to make police stations occasional courts of summary jurisdiction has been recently conferred on county magistrates. A police power of admitting arrested persons to bail in petty cases, with a corresponding duty to exercise the power, is vested in the police in authority at stations. This power has existed throughout the metropolitan police district from the first establishment of the police on its present footing, and also in the City of London and in many populous places under local Acts; and the principle has been recently extended to the country.

The selection of persons for the force is a matter subject to general as well as special regulations, varying in each district according to circumstances of place and time. Testi-

monials as to character and antecedents should be and are in practice always required. For health a medical examination is enforced; as to general education, reading and writing are usually required; special education for police duties is necessarily unattainable before entry, but in the metropolitan police force of England approved candidates are admitted on probation, and drilled. When finally approved of, on admission to the force they make a declaration, as already stated, to duly serve.

Discipline is enforced by dismissal, reprimand, fines, removal to another division, or degradation in rank. Violation or neglect of duty may be punished by summary conviction. Discipline.

For the detection of crime and offences it is obviously necessary that some members of the force should perform their duties out of uniform. Detectives. Some are constantly employed as detectives, others doff their official dress on emergencies. In the English metropolis the detective officers form a distinct branch of the police service, called the criminal investigation department. One of the assistant commissioners of the metropolitan police attends specially to this department, to which a chief superintendent and a separate staff of inspectors and sergeants are attached, having an office in Scotland Yard, with officers of the department placed in the divisions of the district. The qualifications of the principal officers are special, and they are selected for their aptitude, knowledge of foreign languages, and a variety of circumstances rendering the application of the ordinary routine of training undesirable and impracticable. Constables and sergeants of the departments are selected from the general body of the force. Officers of the detective department of the metropolis in the performance of their various duties travel all over the globe, to foreign states as well as to the colonies. The number of detective officers in England and Wales for 1882-83 was 551.

The chiefs of the metropolitan police force are the commissioner and three assistant commissioners, one acting in place of a director of criminal investigations, who has recently retired. A legal adviser to the commissioners is appointed by the secretary of state. Besides the divisional superintendents, there are now two district superintendents, who visit the whole of the divisions. All promotions in the service up to the rank of superintendent are made from the next rank below. When vacancies occur the rule is to recommend to the commissioner those best qualified in all respects, seniority of service being duly considered; but an educational examination by the civil service commissioners is requisite. A different standard and subject of examination is provided for each rank: (1) constables for sergeants; (2) sergeants for inspectors; (3) inspectors for superintendents.

Orders having the approval of the secretary of state for the government of the police of the metropolis in a variety of matters are printed and issued daily throughout the district. The majority of these orders relate to incidents and contingencies of the passing hour, and affect particular divisions; others are of a permanent character, and require attention throughout the district. Such orders form the practice of the police in almost all matters of detail either not specifically regulated by Act of Parliament or requiring explanation and elucidation; and, if they are carefully considered and prepared, their issue must produce a uniform code of police procedure for the force.

The cost of a police system is defrayed from a fund formed by local rates or by imperial funds, or both, and in part by the appropriation of fines and the fees payable by law in respect of the performance of individual duties, but not permitted to be retained by the performer. This fund is collected and expended through the medium of a re-

Main-
tenance.

ceiver, treasurer, or other officer, and a staff of clerks, with the aid of the superintendents, inspectors, and police officers. The regulation and amount of the salaries (which are generally paid weekly or monthly according to the class), depend of course on local and other circumstances, but do not vary frequently. Where agriculture is the general occupation the pay of members of the force is low. Where mining and manufactures compete with agriculture it is higher; where they are the principal business they create a demand for labor which raises the salary of the constable as well as those of other workers. The pay of the constables of the metropolitan district varies from £62, 11s. 6d. [\$304.11] to £83, 8s. 7d. [\$405.46] per annum, that of the sergeants from £88, 12s. 11d. [\$430.82] to £146 [\$709.56], of the inspectors from £88, 12s. 11d. [\$430.82] to £351, 19s. 4d. [\$1,710.56]. The metropolitan police constable is subject to deductions for pension, and he contributes on the average about 2d. [4 cents] a week to gratuities for the widows or orphans of comrades who have recently died, and is under a rent of about 3s. 6d. [88 cents] if single and living out of the section house, and about 6s. 6d. [\$1.58] a week if married. Analogous conditions exist in all the great city forces. The Liverpool constable begins with 26s. 8d. a week [\$6.48]; 8d. [16 cents] a week is deducted at first, and 10d. [20 cents] after a short period, towards pension fund; an average of 4s. [97 cents] a week is spent on the lodgings of a single, and from 5s. 6d. [\$1.33] to 7s. 6d. [\$1.82] on those of a married man. Model scales of pay, which were suggested by the secretary of state in 1879, have been adopted by several county forces in Scotland, but not in burghs.

In addition to fixed salaries, the police system generally provides for rewards for extraordinary diligence and gratuities out of the police fund. Gifts or payments to individual officers by private persons ought to be controlled in a well-regulated system, where good conduct and vigilance ought to be closely watched to ensure promotion in due time. Specially meritorious acts, however, are sometimes admitted for pecuniary recognition by magistrates, or representative bodies. In England the police are not now permitted to participate in Government or other rewards for the discovery of crime. Provision is almost invariably made for pensions by a fund formed by a scale of deductions from pay, as already stated, and to some extent by fines. The general subject of superannuation is, however, too large to be entered upon here. For the ordinary services of the police within their local jurisdiction no charge should fall on particular persons who happen to derive special advantage from such police duty. It is a general benefit for which in one form or another the inhabitants are taxed.

Other incidental expenditure in the performance of duties is met in various ways. The heavy cost connected with the conveyance of prisoners to and from prison on committal and remand is in England, except in Middlesex, borne by the state, being paid by the prison commissioners. The preliminary cost attending the arrest in the first instance is generally borne by the police fund. In some exceptional cases, where the police perform special duties beyond their district, the cost is thrown on individuals putting the law in motion. Thus the costs incurred under extradition treaties and under the Fugitive Offenders' Act in following criminals and bringing them back within the jurisdiction for trial where the offence was committed or arose are not expressly provided for by statute; but the regulations laid down by the secretary of state require all costs to be paid by applicants in the case of fugitive offenders.

The police have special powers in furtherance of their duties; even the exemption from toll (not now of general value) has that aspect. They are not only exempted but disqualified

from various local offices as interfering with the time and attention required for the full performance of their duties. Rules of service generally forbid constables following any trade or occupation of profit even when not on actual duty, and in the metropolitan police district of London this disqualification extends in practice to their wives. The police are protected in the discharge of their duties in a variety of ways. Assaulting, resisting, or wilfully obstructing a peace officer in the due execution of his duty or any person acting in aid of such officer, and assaults with intent to resist or prevent lawful apprehension or detainer, are punishable summarily as well as upon indictment. Refusing to assist a constable in the execution of his duty in order to preserve the peace is an indictable misdemeanor at common law. The law specially provides for offences by the police in stealing or embezzling property entrusted to them in virtue of their employment (24 & 25 Vict. c. 96, §§ 69, 70).

Wearing a distinctive dress or uniform in the general performance of duty is a matter of the highest importance. It commands and has a very great effect in producing obedience and conformity to law and order, and in preventing violence, without the use of even a word or threat; and it has a scarcely less important effect in protecting the public from the illegal or irregular action of the police when on duty, when the dress involves, as it ordinarily does, the exhibition on its exterior of a letter and number.

The extent to which the individual members of a police force are allowed or required to be armed when on duty for the enforcement of the law or for their own protection from violence is a matter of important discretion; for, although the principles of law, entailing or withholding the right of peace officers or private persons to employ weapons of offence, are comparatively well-defined, the emergency depends on a variety of circumstances on which it is extremely difficult for heads of forces to make regulations for the guidance of the men. In general the only weapon carried about the person of a police constable is the familiar wooden staff of office of the peace officer, and that not in the hands openly, but in a sheath at his side and only drawn when required.

The cost of the police in England and Wales for the year ending 29th September, 1883, including salaries and pay, allowances, clothing and accoutrements, horses, harness, forage, buildings, station-house charges, printing, stationery, and other miscellaneous charges was £3,367,678 [\$16,366,915.08], a net increase of £107,598 [\$522,926.28] as compared with the previous year. The cost of the separate forces for the year and the amounts contributed from the public revenue stand thus:

	Total Charge.	Contributed from Public Revenue.
Borough police.....	£857,863	£379,210
County.....	1,101,621	435,133
Metropolitan police (including naval dock-yards and military stations).....	1,317,303	508,183
City of London.....	90,891
Total.....	£3,367,678 [\$16,366,915.08]	£1,322,526 [\$6,427,476.36]

Deducting the City of London police, towards which no contribution is paid from the public revenue, the proportion of the amount so contributed was 39.5. But if the total charge for the metropolitan police is reduced by £131,560 [\$639,381.60] received from public departments for special services rendered by the police, the proportion contributed from the public revenue, computed upon £1,185,743 [\$5,762,710.98] was 42.8

per cent. All moneys received for the service of the metropolitan police between 1st April, 1883, and the 31st March, 1884, amounted to £1,469,930, 4s. 5d. [\$7,143,860.87]. Of this total the sum of £639,751, 7s. 4d. [\$5,109,191.64] was derived from the metropolitan police rate, and £510,933 [\$2,483,134.38] as the contribution from moneys voted by parliament of 4d. [8 cents] per 1£ [\$4.86] upon £30,663,903 [\$149,026,568.58], the assessed rental of property in the metropolitan police district. The pay, clothing, and equipments of the force from constables to superintendents was £1,024,587, 13s. 9d. [\$4,979,496.12].

In concluding this general account of the existing police system, it is well to mention that the old system of parish constables no longer exists as a general institution. As an auxiliary force, although not forming part of the establishment of a police system, special constables form an important resource in the preservation of the peace (see CONSTABLE).

History of the Introduction of the British Police System.—It is a self-evident proposition that the duties of watch and ward, whether under the Statute of Winchester or otherwise (see CONSTABLE), demanded greater attention in populous places than in scattered hamlets. Nevertheless the inefficiency of the arrangements was notorious from an early period, and is well illustrated by the "charge" of a Dogberry and the graver complaints of Lord Burleigh of the dulness of constables. In relation to London alone its state down to 1828 forms a subject not without general interest (see LONDON). Here it must suffice to say that committees of the House of Commons in 1772, 1793, 1812, 1817, 1818, and 1822 produced facts tending to the formation, but with hesitation, of a police establishment. To Dr. Colquhoun, a magistrate, the chief merit is due of having, before the close of the 18th century, in a treatise *On the Police of the Metropolis*, drawn attention to the subject. He pointed out that police in England may be considered as a new science, the properties of which consist, not in the judicial powers which lead to punishment, and which belong to the magistrates alone, but in the prevention and detection of crimes, and in those other functions which relate to internal regulations for the well-ordering and comfort of civil society. His work went through several editions in a very brief period. It was not, however, until 1828 that a committee of the House of Commons, appointed at the instance of Mr. (afterwards Sir Robert) Peel, the home secretary, to inquire into the cause of the increase in the number of commitments and convictions in London and Middlesex, and into the state of the police of the metropolis and of the districts adjoining, reported that a decisive change should be made, and an efficient system of police instituted for the adequate protection of property, and for the prevention and detection of crime in the metropolis. In the following year the famous Act for improving the police in and near the metropolis was passed (10 Geo. IV. c. 44).

The Act constituted a police district, excluding the City of London, with a radius of 12 miles. Two persons were constituted justices of the peace (afterwards called commissioners of police) to administer the Act under the immediate direction of a secretary of state and having a police office in Westminster. This office, established in a room with a table and two chairs, in an outlet from Whitehall, is the origin (as regards police associations) of the far-famed "Scotland Yard," with its now enlarged staff, but still inadequate structural arrangements. A sufficient number of "able men" (at first about 3000) constituted the force to whom were given, when sworn in, the common law powers, privileges, and duties of constables for preserving the peace and preventing robberies and other felonies, and apprehending offenders against the peace, with the duty to obey the lawful commands of the commissioners. The district was formed into divisions and

sections, and ranks established on the same general system as at present exists. A fund was created principally by rates on the district for the maintenance of the force, with rewards for extraordinary diligence and compensation for injuries.

As might have been anticipated, the introduction of the new system of police attracted great public attention. At this distance of time, with the experience of an intervening half century, it is difficult to believe that the change by which the police system became in a few years as much a necessity of towns as their public lighting (and lighting and watching were of much the same age and character, and were frequently coupled in legislation) was regarded otherwise than with the approval of well-regulated minds. It substituted the vigorous action of a really responsible and well-regulated body, acting in an enlarged area, and independently of parochial authorities, for the partial and lax action of a variety of ill-governed and inadequate bodies. Legitimate but passing regrets might be natural as the introduction of vicarious action superseded the necessity for self help and responsibility. No poet could thereafter compose, as a sally of fancy, the adventures of a London citizen between Cheapside and Edmonton mounted on a runaway horse with associated gentlemen galloping after a presumed horse-stealer. To arrest the horse, whether a runaway or stolen, only a blue-coated policeman would thenceforward be seen on the track. The objections raised to the new police were of a more serious although scarcely of a more substantial kind. The assumption that a good police could only be attained at the expense of liberty, and that it necessarily involved some arbitrary principle opposed to the free constitution of the country, had been countenanced even by the report of the committee of 1822, in which it was remarked that it was difficult to reconcile an effective system of police with that perfect freedom of action and exemption from interference which are the great privileges and blessings of society in the country. With such sedate misgivings, it is not to be wondered at, when the system was actually introduced a few years later, that cries arose in the streets of "down with the new police," and that the constables were frequently followed by hooting crowds calling them obnoxious names. By associating them with the statesman who introduced the measure, and calling them "Peelers" and "Bobbies," names perpetuated to the present day and apparently likely to last, a compliment was really paid to the minister and to the force. But at that time Peel was attacked in parliament and suspicion thrown on the Act because the same minister had introduced Roman Catholic emancipation.

Within four years of the establishment of the police force the hostility seems to have culminated. It was evinced by the result of a collision between the police and a meeting of Chartists in Coldbath Fields in May, 1833, in which three police officers were stabbed and one killed with a dagger. At the inquest the coroner's jury returned a verdict of "justifiable homicide," in the teeth of the evidence. The crown thereupon adopted the strong but justifiable course of applying to the Court of King's Bench, and the inquisition was quashed. Committees were appointed by the House of Commons to inquire into the circumstances of the meeting, and also regarding an allegation of inhabitants of the Surrey side that policemen were employed as spies, and a third committee was appointed to inquire into the state of the police and crime in the district. The police system and the force as a whole came out with credit, notwithstanding individual instances of undue exercise of power calling for greater control.

There was no hesitation as to the duty of maintaining the principle of the new system, and the popular hostility gradually died away. After intermediate parliamentary reports and legislation by way of extension, an important Act was passed in 1839, reciting that the system of police established had been found very effi-

cient and might be yet further improved (2 & 3 Vict. c. 47). The metropolitan police district was extended to 15 miles from Charing Cross. The whole of the River Thames (which had been in its course through London, so far as related to police matters, managed under distinct Acts) was brought within it, and the collateral but not exclusive powers of the metropolitan police were extended to the royal palaces and 10 miles around, and to the counties adjacent to the district. Various summary powers for dealing with street and other offences were conferred.

At the same time that the police were put on a more complete footing and the area enlarged, provision was made for the more effectual administration of justice by the magistrates of the metropolis (2 & 3 Vict. c. 71). The changes that occurred in magisterial functions are scarcely less remarkable than the transition from the parish constable to the organized police. The misdirected activity of the civil magistrate in the 17th century is illustrated by the familiar literature of Butler, Bunyan, and others. The zeal of that age was succeeded by apathetic reaction, and it became necessary in the metropolis to secure the services of paid justices. The malpractices of the so-called "trading justices" of the 18th century are described and exposed for all time by Fielding, who honorably performed the duties of justice of the peace for Middlesex and Westminster. At the beginning of the 19th century outside of the City of London (where magisterial duties were, as now, performed by the lord mayor and aldermen) there were various public offices besides the Bow Street and the Thames police offices, where magistrates attended. To the Bow Street office was subsequently attached the "horse patrol," and each of the police offices had a fixed number of constables attached to it, and the Thames police had an establishment of constables and surveyors. The horse patrol was in 1836, as previously intended, placed under the new police. It became desirable that the horse patrol and constables allotted to the several police offices not interfered with by the Act of 1828 should be incorporated with the metropolitan police force. This was effected, and thus magisterial functions were completely separated from the duties of the executive police; for, although the jurisdiction of the two justices, afterwards called commissioners, as magistrates extended to ordinary duties (except at courts of general or quarter sessions), from the first they did not take any part in the examination or commitment for trial of persons charged with offences. No persons were brought before them. Their functions were in practice confined to the discipline of the force and the prevention and detection of offences, by having persons arrested or summoned to be dealt with by the ordinary magistrates whose courts were not interfered with.

Important alterations have been made since 1839 in the arrangements affecting the metropolitan police. In 1856 one commissioner and two assistant commissioners were substituted for two commissioners, and a third assistant commissioner has now (1884) been added. In 1866 jurisdiction was given to the metropolitan police in the royal naval dock yards and principal military stations of the war department in England and Wales, and within 15 miles, with the restriction that the powers and privileges of the constables of the metropolitan police when without the yards, naval and marine hospitals and infirmaries, and marine barracks or stations, and not on board or in any ship, vessel, or boat belonging to the queen or in her service, shall only be used in respect of the property of the crown or of persons subject to naval or marine or military discipline (23 & 24 Vict. c. 135).

Under this Act the metropolitan police exercise jurisdiction and perform duties extending from Chatham on the east and Dover and Portsmouth on the south to Devonport, Portsmouth, and Pembroke on the west, and of course including Aldershot. The expenses incurred are defrayed by parliament.

Connected with the last-mentioned Act, and in consequence of it, has been the exercise for eighteen years by the metropolitan police of the powers of the Contagious Diseases Act, 1866, and the medical examination of women under it,—a much debated and warmly contested power. The refusal in 1883 by the House of Commons to provide money for the expenses of the Act led to the discontinuance of action by the metropolitan police under it.

The Metropolitan Streets Act, 1867, for regulating the traffic in the metropolis, and for making provision for the greater security of persons passing through the streets and for other purposes, gives great discretionary power to the commissioner of police whether of the metropolis or of the City of London, in relation to prescribing special limits, with the approval of a secretary of state, within which regulations to prevent obstructions in the streets (without interfering with other powers) may be made and enforced. Apart from the special limits, general regulations are prescribed as to hackney carriages, stray dogs, and various other matters.

As already observed, the Acts noticed as to the metropolitan police district did not apply to the City of London, which was and is left as an island surrounded by the metropolis. The nightly watch and "bedels" within the City were regulated, and rates imposed for the purpose, in the reign of George II. In 1839, on the same day that the Act of Parliament passed with respect to the metropolitan police, a corresponding Act was passed for the City of London and a salaried commissioner of the police for the City and its liberties appointed by the common council. The power to make regulations relative to the general government of the police is vested in the commissioner, subject to the approbation of the mayor and aldermen and a secretary of state. In case of emergency the secretary of state may, at the request of the lord mayor, authorize the metropolitan police to act within the City of London under the command of their own officers, and on the other hand the lord mayor may, at the request of the secretary of state, in the like emergency, authorize the City police to act under their own officers within the metropolitan police district. The Act gives various special powers as to offences corresponding with the Metropolitan Police Act of 1839. It provides for a police rate, and the corporation is required to pay out of its revenues a fourth part of the expenses of the police force. No rated person is liable to any watch or ward by virtue of the Statute of Winchester (13 Edw. I.), and the ancient custom of electing ward constables is suspended.

In the article LONDON (vol. xiv. p. 843) some statistics are given as to the police courts of the metropolis, and the state of crime and the proportion of police to the population under the last census.

In considering the introduction of the police system into the rest of England, it is to be borne in mind that in many towns and places an organized system of watching by paid officers, whether constables, watchmen, or police, was established by local acts of Parliament, at various dates, but especially in the early part of the present century.

An attempt at a paid county force was made in 1829 (in the same year with the Metropolitan Police Act), but not on corresponding lines, by a local Act to enable the magistrates of the county palatine of Chester to appoint special high constables and assistant petty constables (10 Geo. IV., c. 97). In 1830, and again three years later, provision was made to facilitate voluntary lighting and watching parishes throughout England and Wales. In 1835 the regulation of municipal corporations included power (since renewed) to appoint, by a watch committee, constables called "watchmen" paid by a watch rate.

Great facilities having been given by the legislature for the appointment of special constables (an auxiliary elsewhere noticed), provision was made in 1839 for the

appointment of county paid constables where the ordinary officers for preserving the peace were insufficient for that purpose and for the protection of the inhabitants and for the security of property within the county. The number recommended (not exceeding one man for every thousand of the inhabitants, after deducting corporate boroughs already provided for, a restriction in after years removed from the statute book) and the rates of payment were required to be reported to the secretary of state, who made and laid before parliament rules for the government, pay, clothing, accoutrements, and necessities of such constables; and thereupon the justices appointed, subject to the approval of the secretary of state, a chief constable, who had the appointment, control, and disposition (subject to the approval of the justices) of the other constables, and a deputy and superintendent to be at the head of the constables in each division of the county. On these constables were conferred all the powers and duties of constables by the common law or statute.

At first the salaries and allowances and expenses of the Act were paid out of the county rate (2 & 3 Vict. c. 93), but in the following year (1840) the Act was amended and extended, and a separate police rate levied in the county. Provision was at the same time made for a superannuation fund and for "station houses and strong rooms," and for consolidating the police of a borough with the county; and on the other hand, as the number of constables needed may be different in different parts of the same county, it might be divided into police districts, each district paying for its own constables. Power is given to the chief constable to appoint (with the approval of the justices) additional constables at the cost of individuals, but subject to the orders of the chief constable.

In 1842 an important statute was passed enacting that for the future no appointment of a petty constable, head-borough, borsholder, tithing man, or peace officer of the like description should be made for any parish at any court-leet, except for purposes unconnected with the preservation of the peace, and providing, as a means of increasing the security of persons and property, for the appointment by justices of the peace in divisional petty sessions of fit persons or their substitutes to act as constables in the several parishes of England, and giving vestries an optional power of providing paid constables. The justices in quarter sessions were empowered to provide lock-up houses for the confinement of persons taken into custody by any constable and not yet committed for trial, or in execution of any sentence, or instead to appropriate for that purpose existing lock-up houses, strong rooms, or cages belonging to any parish (5 & 6 Vict. c. 109). Constables appointed under this Act were made subject to the authority of the chief constable or superintendent, if any, appointed under the Act of 1839.

Under the Acts of 1839 and 1840 the establishment of a paid county police force was optional with the justices. After a further interval of fifteen years it was found expedient, for the more effectual prevention and detection of crime, suppression of vagrancy, and maintenance of good order, that further provision should be made for securing an efficient police force throughout England and Wales, and the previous optional power became compulsory (the Police Act, 1856). In every county in which a constabulary had not been already established under the previous Acts for the whole of the county, the justices in quarter sessions were required to proceed to establish a sufficient police force for the whole of the county and to consolidate divisions so as to form one general county police establishment,—subject, however, to the power by the queen in council to require the justices to form separate police districts, as provided for, in the earlier Acts. The privy council might arrange terms of consolidation of a borough police with the county.

In 1869 provision was made for the abolition of the

old office of high constable (the High Constables Act, 1869); and the establishment of an efficient police having also rendered the general appointment of parish constables unnecessary, the appointment ceased, subject to the appointment by vestries of paid constables who are subject to the chief constable of the county (the Parish Constables Act, 1872). Thus under combined provisions the police system was established and has since continued throughout England.

In Scotland legislation for a system of police began early in the century by local Acts for Edinburgh and Glasgow, some containing provisions of great importance. The police of towns and populous places is now regulated chiefly by the General Police and Improvement (Scotland) Act, 1862, and the county police by an Act of 1857 (20 & 21 Vict. c. 72), under which counties are formed into police districts. Some details of the government, numbers and costs have been already given.

The police in Ireland comprises two forces—the Dublin metropolitan police and the royal Irish constabulary. Dublin was in 1806 formed into a district called "the police district of Dublin metropolis" (48 Geo. III. c. 140). After intermediate amendments in 1836, concurrently with the consolidation of police law for Ireland generally, the Dublin system was placed on the lines of Sir Robert Peel's Act of 1829 for the metropolis of London—the chief secretary of the lord lieutenant standing in the place of the secretary of state for the home department (6 & 7 Will. IV. c. 29); and six years later the systems were further assimilated (5 & 6 Vict. c. 22). Several alterations were made subsequently, and police courts regulated. The Dublin police is under the immediate direction of one commissioner and an assistant commissioner and the offices of receiver and secretary are consolidated. The royal Irish constabulary dates from 1836, when the laws relating to the constabulary force in Ireland were consolidated and a number of older Acts repealed (6 & 7 Will. IV. c. 13). This Act, although often amended, is the foundation of the existing police system in counties, towns and baronies throughout Ireland except in the Dublin metropolitan district. An inspector general, resident in Dublin and having an office there, and appointed by the lord lieutenant, has the general direction of the constabulary, and with the approbation of the lord lieutenant frames rules for their general government, classification, and distribution. In this way a uniform administration of police law prevails throughout Ireland without interfering with the Dublin metropolitan police. Under the inspector general there are a deputy inspector general and assistant inspectors general. The Irish constabulary is regarded as a semi-military force. Every man lives in barracks. It does not interfere with the Dublin metropolitan police, but a reserve force is established at a depot in Dublin. The strength and pay of the force have been already noticed.

Police forces have been formed in all the British colonies, including the Dominion of Canada, mainly on the lines established in the mother country, having for their basis of action the common law existing there.

The early legislation for Sydney followed very closely the metropolitan police Acts, and some of the existing Acts of the Australian colonies exhibit great skill. Colonial forces generally are sworn to serve the queen, and an Act of the colonial legislature of New South Wales in 1853 made provision for the engagement in Great Britain of persons to serve in the police force of New South Wales. The general features of the Australian police comprise a chief commissioner or other head for each colony or district, appointed by the governor in council, with various grades of officers as at home, some appointed by the governor and the rest by the head of the police. The expense of the police establishments is borne by the colonial revenue (5 & 6 Vict. c. 76, § 46; 13 & 14 Vict. c. 59, § 23).

Nearly the whole of British India is divided into police districts, the general arrangements of the system of the regular police resembling in most respects those of the English police, but differing in details in the different presidencies. All are in uniform, trained to the use of firearms, and drilled, and may be called upon to perform military duties. The superior officers are nearly all Europeans, and many of them are military officers. The rest are natives, in Bombay chiefly Mohammedans. The organization of the police was not dealt with by the criminal code which came into force in 1863, but the code is full of provisions tending to make the force efficient. By that code as well as by the former code the police have a legal sanction for doing what by

practice they do in England: they take evidence for their own information and guidance in the investigation of cases, and are clothed with the power to compel the attendance of witnesses and question them. The smallness of the number of the European magistrates and other circumstances make the police more important and relatively far more powerful in India than in England (Stephen). The difficulties in the way of ascertaining the truth, and investigating false statements and suppressed cases, are very great.

As regards the rural police of India every village headman, and the village watchman as well as the village police officer, are required by the code to communicate to the nearest magistrate or the officer in charge of the nearest police station, whichever is nearest, any information respecting offenders.

Reports indicating an increase in the number of dacoities and crimes of violence since 1880, especially in Rajputana, Central India and Hyderabad, are cited as proving the necessity for a system of detective police embracing the whole of India. A scheme for that purpose has been matured and will probably be carried out.

Taking Lower Bengal as an illustration of the existing system throughout India, the superior ranks of the police comprise an inspector general, deputies, district superintendents of different grades, assistant superintendents and probationers. The subordinate officers consist of inspectors of four grades, sub-inspectors (who are in charge of police stations), head constables and constables. The total budget grant for the year 1881-82 (the last examined) for the police department was 3,695,572 rupees [\$1,796,047.99] on a sanctioned strength of 78 superior officers, 3081 subordinate officers, and 14,588 constables, excluding the municipal police but including the civil police and frontier police of the Chittagong hill tracts and the railway police. The strength of the municipal police was 371 officers and 5702 constables. The cost of the force employed on purely police work was 2,154,600 [\$1,047,135.60] rupees—the cost per head of the total population being 6.2 pice [1.54 ct.]. The proportion of police to population was in Bengal proper 1 to 3933. The number of offences reported during the year was 104,153. The percentage of reported cases not inquired into is under four.

In India generally, including Assam and British Burmah, the total regular police of all kinds in 1881 was 147,200. The cost was £2,324,786 [\$11,258,459.96], of which £2,075,525 [\$10,087,051.50] was payable from imperial or provincial revenues, and the remainder from other sources. The rural police are not paid by the state, but by village cesses.

In Bengal and the Punjab there are 14 policemen to every 100 square miles, and in the Northwestern Provinces and Oudh 27. The ratio of these figures is explained partly by the greater density of population and partly by the frequency of crime.

The police force of the British empire, metropolitan, municipal and rural together, is about 210,000. Of this total, 51,000 are in the United Kingdom and 147,000 in India, the remainder being in the colonies and dependencies. If to this total be added the number of village police in India who are legally recognized, whose number is not less than 350,000, the grand total of the police for the empire is 560,000. Thus we have for the whole empire an average of one policeman to every 571 of the people and to every 16 square miles (Sir Richard Temple).

The United States of America have a system of police closely resembling that of England, and founded similarly on Acts of the legislature combined with the common law applicable to peace officers. Congress as well as the States separately may establish police regulations, and it is to be observed that the criminal law of England has been reproduced in various shapes in nearly all the States. The source of revenue for the maintenance of the police is taxation of real and personal property. Every State and every city in a State has its separate special administration. For the purposes of this article New York must suffice. The regulations of the police of Brooklyn, Philadelphia, and other cities present the same general features.

The police department of the city of New York consists of a "board of police" composed of four "commissioners" (appointed by the mayor with the consent of the board of aldermen) and the "police force" and officers appointed by the board. The board, consisting of the commissioners, is the head of the police department, and governs and controls its business; it is invested with and exercises all the powers conferred by law upon the police department, makes appointments, and by rules and regulations through a superintendent prescribes the general discipline of the department. The orders cannot, however, conflict with the

constitution of the United States nor with the constitution or laws of the State of New York.

The police force of the city comprises officers ranking as follows:—superintendent of the whole force, four inspectors (the whole area of the city being divided into four inspection districts, subdivided into precincts, with an inspector to each), sergeants and roundsmen, who are visiting officers—the body of the force being termed "patrolmen," with "overmen" at stations and prisons.

The force (clothed in uniform) is divided into as many companies as there are precincts, and such other companies and "squads" as the board may order. The superintendent is the chief executive officer of the force, subject to the orders, rules, and regulations of the board, and it is his duty to enforce in the city all the laws of the State and ordinances of the city, and the rules and regulations of the police board. The superintendent promulgates written or printed orders to the officers and members of the police force not inconsistent with law or the rules and regulations of the board. It is the duty of the police force at all times of the day and night within the city and county of New York, and they are accordingly empowered, to especially preserve the public peace; prevent crime; detect and arrest offenders; suppress riots and insurrections; protect the rights of persons and of property; guard the public health; preserve order at every primary and public election; remove nuisances existing in public streets, roads, places, and highways; repress and restrain disorderly houses and houses of ill-fame; arrest all street beggars and mendicants; provide a proper police attendance at every fire in order that the firemen, fire-engines, and property exposed may be suitably assisted or protected; assist, advise, and protect immigrants, strangers, and travellers in public streets, or at steamboat and ship landings or railroad stations; enforce any law relating to the suppression and punishment of crime, or to the observance of Sunday, or regarding pawnbrokers, or mock auctions, or emigration, or elections, or gambling, or intemperance, or lotteries, or lottery policies, or vagrants, or disorderly persons, or the public health, or any ordinance or resolution of common councils, within the said district, applicable to police, health, or criminal procedure.

Special regulations are made on these and other kindred subjects, such as the regulation of traffic, preventing obstructions, the visitation of places of amusement, public houses and drinking places, observation of servants in charge of houses, and of suspicious persons, lost children, processions, balls and parties, elections, etc., and the attendance of an adequate number of police at every assembly of citizens.

The arrest of persons with or without process does not call for special notices distinguished from the common law and statute law in England, and the practice as to the entry of charges and taking bail by the police is akin to the practice in the English metropolis, but the rules are somewhat stricter. A squad is organized for the sole purpose and duty of serving criminal process. Persons making complaint of a felony or misdemeanor may be required to make affirmation or oath which the police officers have power to administer. Charges against police, whether by members of the force or citizens, are made and dealt with under strict rules, and are tried upon written charges by one or more of the commissioners in power, a committee dismissing charges or directing their trial. Evidence is taken upon oath, and if the case is heard by less than three commissioners no judgment can be acted on until the witness is brought before and examined by all the commissioners. The board draws, by its president, on the treasurer of the city for the cost of arrest and conviction of criminals and others endangering the safety of the community and procuring information the use of which may prevent crime and enable the department to perform its important duties more successfully and with greater satisfaction to the public. The sum so drawn is charged as a "secret service fund." A place is provided in accordance with statute law for the detention of such witnesses as are unable to furnish security for their appearance in criminal proceedings.

The detective force, called the "detective squad," consists of a captain and other members assigned by the board to detective duty. This portion of the force has an office, as other portions of the police force, and is under the direct orders of the superintendent, to whom reports are made, and who in turn reports to the board. There is also a "special service squad" under the officer commanding the detective force.

There is a sanitary code, and a "sanitary police company" is set apart from the police force by the board of police, performing duties assigned by the board. The captain of the sanitary company assigns policemen to act as school officers. There are harbor police, a police steamboat.

and steam-boiler inspection squad to enforce the statute law on the subject, an "ordinance police squad" to enforce ordinances of the corporation, and a "property office."

Members of the force are subject to rules; at the discretion of the board, on written application, they are permitted to receive rewards or presents for services rendered by them in the discharge of duties which are both "meritorious and extraordinary," but for such only.

Admission to the force, examination, instruction, drill, and discipline are provided for by special regulations. The right of every member of the police force to entertain political or partisan opinions, and to express the same freely when such expression shall not concern the immediate discharge of his official duties, as well as the right of the elective franchise, is deemed sacred and inviolable; but no member of the force is permitted to be a delegate or representative to, or member of, or to take part in any political or partisan convention, whose purpose is the nomination of a candidate or candidates to any political office. Upon the days of election for public offices held under the laws of the State, he must do all within his power to preserve the peace, protect the integrity of the ballot box, enforce the rights of lawful voters, and prevent illegal and fraudulent voting.

The estimated salaries for the police of New York for 1884, comprising upwards of 2816 members of the force of all ranks, amounted to \$3,328,333, besides the salaries of the clerical force. The appropriations for the maintenance of the city government (including the police) are made by the board of estimate and apportionment, composed of the mayor, comptroller, president of the board of aldermen, and president of the department of taxes and assessments. Some police statistics are given in the article NEW YORK (*q. v.*).

Looked at from a general point of view, the police in France.

France may be regarded as divided into two great branches—administrative police (*la police administrative*) and judicial police (*la police judiciaire*),—the former having for its object the maintenance of order, and the latter charged with tracing out offenders, collecting the proofs, and delivering the presumed offenders to the tribunals charged by law with their trial and punishment.

Police duties are exercised under the minister of the interior, in the departments and municipalities by the prefects and sub-prefects, appointed by the president of the republic, and mayors, having as auxiliaries the commissaries of police and other officers (appointed by the president but under the orders of the prefects). One of the chief prerogatives of the administrative police is to make rules to ensure public order. Of these rules some embrace general interests of the state, these being regulations of high or grand police; others have no other object than the ruling of the particular district and its inhabitants, and are simply termed police regulations. According as it deals with the general interests of the state or only with those of a municipality, the administrative police is said to be general or municipal; and each of these branches admits of other divisions according to the subject. The *police générale*, besides more obvious matters, includes all matters relating to public health, the regulation of prostitution, the inspection of food, the carrying on of trades and manufactures; and in relation to the welfare of the state it embraces public meetings, banquets, societies and clubs, cafés and public places, and the enforcement of laws relating to the publication and distribution of printed or written matter, the sale of journals, the surveillance of strangers or fugitives, the system of passports, the sale of gunpowder and firearms, designs against the state, and a variety of such matters. In this way the police who look after the safety of the state is closely allied with political matters (*la police politique*). Under a government really representing the popular will the duties of the *police politique* are trifling or at least innocuous, but under a despotic government they become of the highest importance. It is matter of history which cannot be treated of here that under Louis XIV. and in succeeding times the most unpopular and unjustifiable use was made of police as a secret instrument for the purposes of despotic government. Napoleon availed himself largely of police instruments, especially through his minister Fouché. On the restoration of constitutional government under Louis Philippe police action was less dangerous, but the danger revived under the second empire.

The ministry of police created by the act of the Directory in 1796 was in 1818 suppressed as an independent office, and in 1852 it was united with the ministry of the interior.

The detection and punishment of crime is theoretically as well as practically regarded by the French as essentially a matter of public concern, and to be provided for by public officials appointed for that purpose, and on the other hand in every French criminal proceeding, from the most trifling to the most important, every person injured by the offence may make himself *partie civile*. It follows that in

many features the French police is organized in a different manner from the British, and has some very different duties (Stephen). An observation has been already cited, that neither in England nor in America is there a system of espionage by which private matters can be made the subject of police investigation or interference. On the other hand the English system is open to the observation that the police, in practice at least, are powerless to protect from annoyance in many matters essential to perfect rule. Short of absolute indecency or obscenity, printed matter of a scurrilous and offensive kind is openly sold in the streets without police interference; and, owing apparently to the much-abused maxim that an Englishman's house is his castle, the quiet and freedom from annoyance in the performance and fulfilling of the daily duties and engagements of life are not secured. The annoyance to which Carlyle was subject is only an illustration of the almost daily complaints that arise in the English metropolis. Although the noise of a bell may be the subject of indictment or injunction, the officers of police do not complain of or even remonstrate with an inconsiderate or selfish neighbor in such a matter, or even in still greater annoyances, such as those arising from animals kept in a state of confinement (not affecting public health), because the source of annoyance is within private territory, or because there is no summary mode of dealing with it. It is unreasonable that complainants should be told, as they are every day, and correctly, by magistrates, that the annoyances which render the enjoyment of life impracticable may be subject of indictment or injunction, but not of summary police intervention. The fear of drawing down ridicule akin to Verges's direction to the watch, "If you hear a child cry in the night, you must call to the nurse to bid her still it," probably stands unduly in the way of police interference with real nuisances.

It is not, however, in the minute details of regulation and inspection of the incidents of every-day life that the distinctions between the police systems of the two countries chiefly consist. Such distinctions have of late years greatly diminished; the intervention in all matters of health, for example, places the English system more akin to the French, and on the other hand all travellers of mature years can testify to the mitigation and even total cessation in France, and on the Continent generally, of the minute investigation of a stranger who is not a "suspect." "To the word espionage a stigma is attached," says Bentham. "Let us substitute the word inspection, which is unconnected with the same prejudices. If this inspection consists in the maintenance of an oppressive system of police, which subjects innocent actions to punishment, which condemns secretly and arbitrarily, it is natural that such a system and its agents should become odious. But if the inspection consists in the maintenance of a system of police for the preservation of the public tranquility and the execution of good laws, all its inspectors and all its guardians act a useful and salutary part; it is only the vicious who will have reason to complain, and it will be formidable to them alone." It is with reference to criminal matters and the *police judiciaire* that important distinctions exist between the French and English systems. In every *arrondissement* there is a *juge d'instruction* who makes the first formal inquiry in criminal cases; and in every tribunal of first instance, or *tribunal correctionnel*, there is a *procureur de la république* who with deputies forms the *ministère public* of that court. In the court of the *juges de paix* (who may be compared to police magistrates) the commissary of the police is the *ministère public*. The *juges de paix*, the *maire*, the commissaries of police, the *gendarmérie*, and in rural districts the *gardes champêtres* and the *gardes forestières*, are officers of the judicial police; and by the *Code d'Instruction Criminelle* all these officers, even the *juges d'instruction* are under the orders of the *procureur-général*. The vocations of these officers as well as the courts are briefly explained in the article FRANCE (vol. ix. p. 452).

Sergents de ville, in Paris now called *gardiens de la paix* (the name having been changed thus in September, 1870), are the nearest equivalents of English police constables and are not officers of the *police judiciaire*. Their powers in preserving the public peace closely resemble the common law powers and duties and protection of the English constable. Their reports of cases have not the authority of a *procès verbal*.

In Paris, as elsewhere, the *préfet de police* is at the head of the force, with *commissaires de police*, appointed by the president of the republic on the nomination of the minister of the interior, but acting under the orders of the prefect, and having both administrative and judicial duties. The commissaries see that the laws relating to good order and public safety are observed, and that the police orders are executed, and take special action in serious matters. As officers of the judicial police they are the auxiliaries of the

procureur of the republic in correctional and criminal police action, and in the ordinary police tribunal (*le tribunal de simple police*) they exercise the functions of magistrates.

The organization of the central administration (*administration centrale*) comprises three classes or functions which together constitute *la police*. First there is the office or cabinet of the prefect for the general police (*la police générale*), with three bureaux having for their special object the safety of the president of the republic, matters connected with the use of arms, various societies, the regulation and order of public ceremonies, theatres, amusements and entertainments, movements of troops, the military police (*la police militaire*), and various other matters; secondly, the judicial police (*la police judiciaire*) already spoken of, with five bureaux, in constant communication with the courts of judicature, and including the service of the prisons of the Seine, matters relating to aliens, and the protection of children; thirdly, the administrative police (*la police administrative*), with four bureaux, including everything relating to supplies, navigation, public carriages, animals, firemen, public health, and the enforcement of the law respecting the employment of young persons. Some minor matters are under the supervision of the prefect of the Seine. Concurrently with these divisions there is the municipal police, which comprises all the agents in enforcing police regulations in the streets or public thoroughfares, acting under the orders of a chief (*chef de la police municipale*) with a central bureau. The municipal police is divided into two principal branches—the service in uniform of the *gardiens de la paix*, and the service out of uniform of *inspecteurs de police*, the latter a comparatively small number.

For purposes of municipal police, Paris is divided into twenty *arrondissements* (corresponding in a great measure with the divisions of the metropolitan police of England), which the uniform police patrol.

The total police strength of the Paris *arrondissements*, according to the latest return, showed 5932 *gardiens de la paix*, each *arrondissement* officered by an *officier de paix* (an office peculiar to Paris), with 3 or 4 brigadiers and from 24 to 27 sous-brigadiers under his command. There are two divisional inspectors.

Besides these divisional *gardiens de la paix* police, there is a central administration consisting of 6 central brigades of 100 each, 4 of the brigades carrying out the orders of the prefecture at theatres, assemblies, races, and in the Bois de Boulogne, and elsewhere in the capital where their presence is required, while the 5th brigade regulates traffic generally, and the 6th prevents obstructions in the markets.

The *service de sûreté*, or detective department (out of uniform), with which is now amalgamated the *brigade des mœurs* (which deals with public morals, houses of ill fame, prostitutes, and so forth), comprises a commissary, principal inspectors, brigadiers, and 211 inspectors. There are a number of other branches of service including a fire brigade. The proportion of police to inhabitants as last estimated is 1 in 352.

The pay of the *gardiens de la paix* is from 1400 [\$254.80] to 1700 [\$309.40] francs; brigadiers, 2000 [\$364] francs; sous-brigadiers, 1800 [\$327.60] francs; *officiers de paix*, 3000 [\$546] to 6000 [\$1092] francs. The estimate of expenditure of the whole Paris police for 1884 was 23,952,631 [\$4,359,378.84] francs—of which the state contributed 7,693,825 [\$1,400,276.15] francs.

Whether the police of Paris are more effective than those of the English metropolis is doubted. Persons who are best entitled to express an opinion, having practical experience, think that, while a multitude of offices and officers for a multitude of subjects and stages of investigation—a system, in short, of bureaucracy—exists which creates an impression, the actual detection of grave offences is not commensurate with the display of attention.

It is impossible in the narrow limits of this article to go through all the police forces of Europe. It must suffice to allude to a few principal states, noting the police forces of their capitals as illustrating the systems. Taking the Berlin force as illustrative of the police system in the German empire, police duties are as various as in France; the system includes a political police controlling all matters relating to the press, societies, clubs, and public and social amusements. Police duties are carried out under the direction of the royal police presidency, the executive police force comprising a police colonel, with, besides commissaries of criminal investigations, captains, lieutenants, acting lieutenants, sergeant-majors, and a large body of constables (*Schutzmänner*). The total in 1883-4 amounted to 3441 executive officers, including criminal investigation officers, the political police, and the department for the supervision of prostitution. Taking the population of Berlin from the statistical bureau of 27th July, 1884, at 1,242,820, this gives 361 to each officer. The

pay of the police is principally provided from fiscal sources, and varies in an ascending scale from 1125 marks and lodging allowance for the lowest class of constable.

Taking Vienna in the same way as illustrative of the Austrian police it is to be observed that there are three branches—(1) administration; (2) public safety and judicial police; and (3) the Government police. At the head of the police service in Vienna there is a president of police, and at the head of each of the three branches there is an *Oberpolizeirath* or chief commissary. The head of the Government branch sometimes fills the office of president. Each of the branches is subdivided into departments at the head of which are *Polizeiräthe*. Passing over the subdivisions of the administrative branch, the public safety and judicial branch includes the following departments: the office for public safety, the central inquiry office, and the record office or *Evidenzbureau*. The Government police branch comprises three departments: the Government police office, the press office, and the *Vereinsbureau* or office for the registration of societies.

The *Sicherheitswache* or executive police of Vienna consists of a central inspector and chief, district, divisional, and other inspectors, with about 2500 constables *Sicherheitswachmänner*. The detective department comprises a chief and other inspectors, and 130 agents. In July, 1884, the proportion of police constables to the inhabitants was 1 to 436. In the latest return, the entire police service comprises 2816 persons, at a cost of 2,355,710 [\$1,144,875.06] florins—of which the state contributes 1,730,740 [\$837,679.44] florins, and the communes the greater part of the remainder. The pay of the constable ascends from 360 [\$174.96] florins with allowances of 90 [\$43.74] florins.

It is obvious that there is a general resemblance between the organization and scope of the police forces of Germany and Austria and of France.

In Belgian municipalities the burgomasters are the heads of the force, which is under their control. The administrator of public safety is, however, Belgium, specially instructed by the minister of justice to see that the laws and regulations affecting the police are properly carried out, and he can call on all public functionaries to act in furtherance of that object. The administrator of public safety is specially charged with the administration of the law in regard to aliens, and this law is applied, as in the case of Victor Hugo, to persons stirring up sedition. The duty of the *gendarmérie*, who constitute the horse and foot police, is generally to maintain internal order and peace. In Brussels as elsewhere the burgomaster is the head, but for executive purposes there is a chief commissary (subject, however, to the orders of the burgomaster), with assistant commissaries and commissaries of divisions and other officers, and central and other bureaux, with a body of agents (police constables) in each.

There are two main classes of police functions recognized by law, the administrative and the judicial police, the former engaged in the daily maintenance of peace and order and so preventing offences, the latter in the investigation of crime and tracing offenders; but the duties are necessarily performed to a great extent by the same agents. The two other functions of the judicial police are, however, limited to the same classes of officers, and they perform the same duties as in Paris,—the law in practice there being expressly adopted in Brussels.

In Brussels the police force numbers, according to the latest report, 485 of all ranks. For the population (162,489), this gives 1 to every 335 persons. Strictly speaking there is no detective branch so called, but the special and judicial officers are employed in detection as the necessity arises. The pay and establishment charges are defrayed by local taxation. The annual pay of a constable is 1500 francs.

While this article is going through the press the idea is put forward, in consequence of political disturbances, to place the police of the larger Belgian towns under the control of Government instead of that of the respective municipalities as at present, and establish a sort of prefecture in the police of Brussels. The attempt, if made, will probably meet with opposition from local authorities.

In Switzerland, which is sometimes classed with Belgium as among the least policed states of Europe, the laws of the cantons vary. In some respects Switzerland, they are stricter than in Belgium or even in France. Thus a *permis de séjour* is sometimes required where none is in practice necessary in Paris or Brussels.

In Italy there is in every province a prefect at the head of the police. See ITALY.

The police in the Netherlands, as regards the sources from which its powers are derived, is divided into the state police and the communal police, Netherlands.

the former forming part of the general executive government, and the latter, although regulated by the executive, enforcing general and local police legislation. Regulations for the state police are framed by the minister of justice. For the purposes of the state police the country is divided into five districts, with a director of police at the head of each district responsible for the control and government of the state police within it, and to see that the laws and ordinances for the safety and quietness of the state, the security of persons and property, and the equality of all before the law are carried out. The duty specially includes the supervision of strangers and their admission into and departure from the country, and extends even to the enforcement of shooting and fishing licenses. In each district there is an officer of justice who directs the prosecution of criminal offences.

At the head of the communal police stand the burgo-masters, and under them police commissaries entrusted with the observance of police regulations, whose appointment and removal rest with the crown, but they are paid by the commune. The whole of the communal police are bound to assist the state police; and, on the other hand, the latter assist the police, especially in the country districts. The duties of the officer of justice may be carried out by the commissary of police, who for the time being is an assistant officer of justice. In large communes the police force is divided into several grades. Besides commissaries, of whom one is chief, there are a chief inspector, classes of inspectors, and brigadiers; but the arrangements differ in almost every municipality.

The total strength of the police is 6000; at The Hague there is supposed to be one constable to 1000 inhabitants. Only in Amsterdam, Rotterdam, and The Hague are there special departments of detective police. Police salaries vary in different communes. The highest are at The Hague, and range from 600 [\$243, value of Dutch florins] florins for a third-class constable to 1800 [\$729 value of Dutch florins] florins for a chief inspector. The cost of the state police and the expenses incurred in prosecutions for crime are defrayed by the state. The expenses of the communal police are paid out of local rates on houses and land.

An official Russian document specially obtained for this article affords the following scanty particulars regarding the police in European Russia.

At the head of a police district there is a police master, who has subordinate officers on his staff. A number of constables are appointed, depending on the population. Large towns are subdivided into districts with inspectors and assistants, smaller towns with an assistant inspector. In villages police duties are executed by the inhabitants elected for that purpose, constituting "hundreds" or "tenths" according to the number of inhabitants. There is a control over the villages by the police of the district, and the governor general has a controlling power over all, including the police master. Besides the ordinary police there are police brigades in large towns with duties of a special kind, as attending parades and fêtes. Each member of the brigade has five hundred inhabitants to look after or control. In the capitals there is a secret police having a staff in St. Petersburg of a chief and his assistant, four clerks, and twenty inspectors, and in Moscow of a chief, two clerks, and twelve inspectors.

The principal active duties of the Russian police comprise the enforcement of police laws and the suppression of nuisances, disturbances, and crime. The details of these duties are laid down in a special Act, which is subdivided into different statutes, taken from the criminal code. The provincial towns are governed by a special law, passed in 1876, as supplementary to the already existing law. The towns provide the funds for the maintenance of the police. Laws of 1853 regulated the lodgings and necessities for the whole police staff according to their rank; but a change has been introduced since 1873, and many officers receive payment in the place of lodgings. Police pay varies from 200 [\$154] roubles upwards.

In closing this article, it is well to observe that the distinction between the exercise of judicial power and police functions should be always borne in mind. "The functions of justice and those of the police must be apt in many points to run into one another, especially as the business would be very badly managed if the same persons whose more particular duty it is to act as officers of the police were not upon occasion to act in the capacity of officers of justice. The idea, however, of the two functions may still be kept distinct" (Bentham). The employment of police powers in the ante-judicial part of criminal process,

which previously to the establishment of a police force in England was thought to require an apology as founded on convenience and utility rather than on principle, has become a necessity.

The necessity for a police force as part of any system of orderly government is exemplified by its recent introduction into Egypt. Amid differences of opinion on every subject, and even on the administration of the force and its duties, the abstract propriety of a police force is apparently beyond dispute.

In every country the difficult question, apart from any as to the extent of interference with the freedom of individual action, arises in actual police administration—*Quis custodiet ipsos custodes?*

By whatever name the head of a police force is known, whether as commissioner, chief constable, superintendent, or otherwise, the efficient performance of his duty involves inquiry and judgment upon that inquiry. The character and efficiency of his force must largely depend upon the insight as well as vigor brought to bear upon the individual members of that force.

In relation to the public generally a perfect police code must be full of restraints, with coextensive powers of inquiry, even in matters that do not involve punishment. The extent to which these restraints and powers are applied greatly depends on time and place. Precautions which are necessary, Bentham observes, at certain periods of danger and trouble, ought not to be continued in a period of quietness, and care should be taken not to shock the national spirit. One nation would not endure what is borne by another. (J. E. D.)

POLIGNAC, an ancient French family which had its seat in the Cevennes near Puy-en-Velay (Haute-Loire). Cardinal MELCHOIR DE POLIGNAC (1661-1742) was a younger son of Armand XVI., marquis de Polignac, and at an early age achieved distinction as a diplomatist. In 1695 he was sent as ambassador to Poland, where he contrived to bring about the election of the prince of Conti as successor to John Sobieski (1697). The subsequent failure of this intrigue led to his temporary disgrace; but in 1702 he was restored to favor, and in 1712 he was sent as the plenipotentiary of Louis XIV. to the congress of Utrecht. During the regency he became involved in the Cellamare plot, and was relegated to Flanders for three years. From 1721 to 1732 he acted for France at the Vatican. In 1726 he received the archbishopric of Auch, and he died at Paris in 1742. He left unfinished a metrical refutation of Lucretius which was published after his death by the Abbé de Rothelin (*Anti-Lucretius*, 1745), and had considerable vogue in its day. Count JULES DE POLIGNAC (ob. 1817), grand-nephew of the preceding, was created duke by Louis XVI. in 1780, and in 1782 was made postmaster-general. His position and influence at court were largely due to his wife, the bosom friend of Marie Antoinette; the duke and duchess alike shared the unpopularity of the court, and were among the first who were compelled to "emigrate" in 1789. The duchess died shortly after the queen, but her husband, who had received an estate from Catherine II. in the Ukraine, survived till 1817. Of their three sons the second, Prince JULES DE POLIGNAC (1780-1847), held various offices after the restoration of the Bourbons, received from the pope his title of "Prince" in 1820, and in 1823 was made ambassador to the court of St. James's. In August 8, 1829, he was called by Charles X. to the ministry of foreign affairs, and in the following November he became president of the council. On the revolution of July, 1830, he fled for his life, but after wandering for some time among the wilds of Normandy was arrested at Granville. His trial before the chamber of peers resulted in his condemnation to perpetual imprisonment (at Ham), but he benefited by the amnesty of 1836, when the sentence was commuted to one of exile. During his captivity he wrote *Considérations politiques* (1832).

He afterwards spent some years in England, but finally was permitted to re-enter France on condition that he did not take up his abode in Paris. He died at St. Germain on March 29, 1847.

POLILLO. See PHILIPPINE ISLANDS.

POLITIAN (1454-1494). Angelo Ambrogini, known in literary annals as ANGELO POLIZIANO or POLITIANUS from his birth-place, was born at Montepulciano in Tuscany in the year 1454. His father, Benedetto, a jurist of good family and distinguished ability, was murdered by political antagonists for adopting the cause of Piero de' Medici in Montepulciano; and this circumstance gave his eldest son, Angelo, a claim on the family of Medici. At the age of ten the boy came to prosecute his studies at Florence, where he learned Latin under Christoforo Landino, and Greek under Argyropoulos and Andronikos Kallistos. From Marsilio Ficino he imbibed the rudiments of philosophy. The precocity of his genius for scholarship and poetry was early manifested. At thirteen years of age he began to circulate Latin letters; at seventeen he sent forth essays in Greek versification; at eighteen he published an edition of Catullus. In 1470 he won for himself the title of *Homeriens juvenis* by translating four books of the *Iliad* into Latin hexameters. Lorenzo de' Medici, who was then the autocrat of Florence and the chief patron of learning in Italy, took Poliziano into his household, made him the tutor of his children, and secured him a distinguished post in the university of Florence. Before he reached the age of thirty, Poliziano expounded the humanities with almost unexampled lustre even for that epoch of brilliant professors. Among his pupils could be numbered the chief students of Europe, the men who were destined to carry to their homes the *spolia opima* of Italian culture. Not to mention Italians, it will suffice to record the names of the German Reuchlin, the English Grocyn and Linacre, and the Portuguese Tassinus. Poliziano had few advantages of person to recommend him. He was ungainly in form, with eyes that squinted, and a nose of disproportionate length. Yet his voice was rich and capable of fine modulation; his eloquence, ease of utterance, and copious stream of erudition were incomparable. It was the method of professors at that period to read the Greek and Latin authors with their class, dictating philological and critical notes, amending corrupt passages in the received texts, offering elucidations of the matter and pouring forth stores of acquired knowledge regarding the laws, manners, religious and philosophical opinions of the ancients. Poliziano covered nearly the whole ground of classical literature during the years of his professorship, and published the notes of his courses upon Ovid, Suetonius, Statius, the younger Pliny, Quintilian, and the writers of Augustan histories. He also undertook a recension of the text of the *Products* of Justinian, which formed the subject of one of his courses; and this recension, though it does not rank high in the scale of juristic erudition, gave an impulse to the scholarly criticism of the Roman code. At the same time he was busy as a translator from the Greek. His versions of Epictetus, Herodian, Hippocrates, Galen, Plutarch's *Eroticus*, and Plato's *Charmides* delighted contemporaries by a certain limpid fluency of Latin style and grace of manner which distinguished him also as an original writer. Of these learned labors the most universally acceptable to the public of that time were a series of discursive essays on philology and criticism, first published in 1489 under the title of *Miscellanea*. They had an immediate, a lasting, and a wide renown, encouraging the scholars of the next century and a half to throw their occasional discoveries in the field of scholarship into a form at once so attractive and so instructive. Poliziano was not, however, contented with these simply professorial and scholastic compositions. Nature had endowed him with literary and poetic gifts of the highest order. These he devoted to the composition of

Latin and Greek verses, which count among the best of those produced by men of modern times in rivalry with ancient authors. The *Manto*, in which he pronounced a panegyric of Virgil; the *Ambrà*, which contains a beautiful idyllic sketch of Tuscan landscape, and a studied eulogy of Homer; the *Rusticus*, which celebrated the pleasures of country life in no frigid or scholastic spirit; and the *Nutricia*, which was intended to serve as a general introduction to the study of ancient and modern poetry,—these are the masterpieces of Poliziano in Latin verse, displaying an authenticity of inspiration, a sincerity of feeling, and a command of metrical resources which mark them out as original productions of poetic genius rather than as merely professorial incubrations. Exception may be taken to their style, when compared with the best work of the Augustan or even of the Silver age. But what renders them always noteworthy to the student of modern humanistic literature is that they are in no sense imitative or conventional, but that they convey the genuine thoughts and emotions of a born poet in Latin diction and in metre moulded to suit the characteristics of the singer's temperament.

Poliziano was great as a scholar, as a professor, as a critic, and as a Latin poet at an age when the classics were still studied with the passion of assimilative curiosity, and not with the scientific industry of a later period. He was the representative hero of that age of scholarship in which students drew their ideal of life from antiquity and fondly dreamed that they might so restore the past as to compete with the classics in production and bequeath a golden age of resuscitated paganism to the modern world. Yet he was even greater as an Italian poet. Between Boccaccio and Ariosto, no single poet in the mother tongue of Italy deserves so high a place as Poliziano. What he might have achieved in this department of literature had he lived at a period less preoccupied with humanistic studies, and had he found a congenial sphere for his activity, can only be guessed. As it is, we must reckon him as decidedly the foremost and indubitably the most highly gifted among the Italian poets who obeyed Lorenzo de' Medici's demand for a resuscitation of the vulgar literature. Lorenzo led the way himself, and Poliziano was more a follower in his path than an initiator. Yet what Poliziano produced, impelled by a courtly wish to satisfy his patron's whim, proves his own immeasurable superiority as an artist. His principal Italian works are the stanzas called *La Giostra*, written upon Giuliano de' Medici's victory in a tournament; the *Orfeo*, a lyrical drama performed at Mantua with musical accompaniment; and a collection of fugitive pieces, reproducing various forms of Tuscan popular poetry. *La Giostra* had no plan, and remained imperfect; but it demonstrated the capacities of the octave stanza for rich, harmonious, and sonorous metrical effect. The *Orfeo* is a slight piece of work, thrown off at a heat, yet abounding in unpremeditated lyrical beauties, and containing in itself the germ both of the pastoral play and of the opera. The Tuscan songs are distinguished by a "roseate fluency," an exquisite charm of half romantic half humorous abandonment to fancy, which mark them out as improvisations of genius. It may be added that in all these departments of Italian composition Poliziano showed how the taste and learning of a classical scholar could be engrafted on the stock of the vernacular, and how the highest perfection of artistic form might be attained in Italian without a sacrifice of native spontaneity and natural flow of language.

It is difficult to combine in one view the several aspects presented to us by this many-sided man of literary genius. At a period when humanism took the lead in forming Italian character and giving tone to European culture, he climbed with facility to the height of achievement in all the branches of scholarship which were then most seriously prized—in varied

knowledge of ancient authors, in critical capacity, in rhetorical and poetical exuberance. This was enough at that epoch to direct the attention of all the learned men of Europe on Poliziano. At the same time, almost against his own inclination, certainly with very little enthusiasm on his part, he lent himself so successfully to Lorenzo de' Medici's scheme for resuscitating the decayed literature of Tuscany that his slightest Italian effusions exercised a potent influence on the immediate future. He appears before us as the dictator of Italian culture in a double capacity—as the man who most perfectly expressed the Italian conception of humanism, and brought erudition into accord with the pursuit of noble and harmonious form, and also as the man whose vernacular compositions were more significant than any others of the great revolution in favor of Italian poetry which culminated in Ariosto. Beyond the sphere of pure scholarship and pure literature Poliziano did not venture. He was present, indeed, at the attack made by the Pazzi conspirators on the persons of Lorenzo and Giuliano de' Medici, and wrote an interesting account of its partial success. He also contributed a curious document on the death of Lorenzo de' Medici to the students of Florentine history. But he was not, like many other humanists of his age, concerned in public affairs of state or

diplomacy, and he held no office except that of professor at Florence. His private life was also uneventful. He passed it as a house-friend and dependant of the Medici, as the idol of the learned world, and as a simple man of letters for whom (with truly Tuscan devotion to the Saturnian country) rural pleasures were always acceptable. He was never married; and his morals incurred suspicion, to which his own Greek verses lend a certain amount of plausible coloring. In character Poliziano was decidedly inferior to the intellectual and literary eminence which he displayed. He died half broken hearted by the loss of his friend and patron Lorenzo de' Medici, in 1494, at the age of forty, just before the wave of foreign invasion which was gathering in France swept over Italy.

For the life and works of Politian, consult F. O. Mencken (Leipsic, 1736), a vast repository of accumulated erudition; Jac. Mähly, *Angelus Politianus* (Leipsic, 1864); Carducci's edition of the Italian poems (Florence, Barbera, 1863); Del Lungo's edition of the Italian prose works and Latin and Greek poems (Florence, Barbera, 1867); the *Opera Omnia* (Basel, 1554); Greswell's *English Life of Politian*; Roscoe's *Lorenzo de' Medici*; Von Keumont's *Life of Lorenzo de' Medici*; Symonds's *Renaissance in Italy*, and translations from Poliziano's Italian poems in his *Sketches and Studies in Italy*, which include the *Orfeo*. POLITICAL ECONOMY.

THE present condition of the study of political economy seems to prescribe, as most suitable for these pages, a treatment of the subject different from that adopted in relation to other departments of knowledge. There prevails wide-spread dissatisfaction with the existing state of economic science, and much difference of opinion both as to its method and as to its doctrines. There is, in fact, reason to believe that it has now entered on a transition stage, and is destined ere long to undergo a considerable transformation. Hence it has appeared to be unseasonable, and therefore inexpedient, to attempt in this place a new dogmatic treatise on political economy. What is known as the "orthodox" or "classical" system, though in our time very generally called in question, is to be found set out in numerous text-books accessible to every one. Again, some of the most important special branches of economics are so fully explained and discussed in other parts of the present work (see BANKING, EXCHANGE, FINANCE, MONEY, etc.) as to dispense with any further treatment of them here. It has been thought that the mode of handling the subject most appropriate to the circumstances of the case, and likely to be most profitable, would be that of tracing historically from a general point of view the course of speculation regarding economic phenomena, and contemplating the successive forms of opinion concerning them as products of the periods at which they were respectively evolved.

Such a study is in harmony with the best intellectual tendencies of our age, which is, more than anything else, characterized by the universal supremacy of the historical spirit. To such a degree has this spirit permeated all our modes of thinking that with respect to every branch of knowledge, no less than with respect to every institution and every form of human activity, we almost instinctively ask, not merely what is its existing condition, but what were its earliest discoverable germs, and what has been the course of its development? The assertion of J. B. Say that the history of political economy is of little value, being for the most part a record of absurd and justly exploded opinions, belongs to a system of ideas already obsolete, and requires at the present time no formal refutation. It deserves notice only as reminding us that we must discriminate between history and antiquarianism: what

from the first had no significance it is mere pedantry to study now. We need concern ourselves only with those modes of thinking which have prevailed largely and seriously influenced practice in the past, or in which we can discover the roots of the present and the future.

When we thus place ourselves at the point of view of history, it becomes unnecessary to discuss the definition of political economy, or to enlarge on its method, at the outset. It will suffice to conceive it as the theory of social wealth, or to accept provisionally Say's definition which makes it the science of the production, distribution, and consumption of wealth. Any supplementary ideas which require to be taken into account will be suggested in the progress of our survey, and the determination of the proper method of economic research will be treated as one of the principal results of the historical evolution of the science.

The history of political economy must of course be distinguished from the economic history of mankind, or of any separate portion of our race. The study of the succession of economic facts themselves is one thing; the study of the succession of theoretic ideas concerning the facts is another. And it is with the latter alone that we are here directly concerned. But these two branches of research, though distinct, yet stand in the closest relation to each other. The rise and the form of economic doctrines have been largely conditioned by the practical situation, needs, and tendencies of the corresponding epochs. With each important social change new economic questions have presented themselves; and the theories prevailing in each period have owed much of their influence to the fact that they seemed to offer solutions of the urgent problems of the age. Again, every thinker, however in some respects he may stand above or before his contemporaries, is yet a child of his time, and cannot be isolated from the social medium in which he lives and moves. He will necessarily be affected by the circumstances which surround him, and in particular by the practical exigencies of which his fellows feel the strain. This connection of theory with practice has its advantages and its dangers. It tends to give a real and positive character to theoretic inquiry; but it may also be expected to produce exaggerations in doctrine, to lend undue prominence to

particular sides of the truth, and to make transitory situations or temporary expedients be regarded as universally normal conditions.

There are other relations which we must not overlook in tracing the progress of economic opinion. The several branches of the science of society are so closely connected that the history of no one of them can with perfect rationality be treated apart, though such a treatment is recommended—indeed necessitated—by practical utility. The movement of economic thought is constantly and powerfully affected by the prevalent mode of thinking, and even the habitual tone of sentiment, on social subjects generally. All the intellectual manifestations of a period in relation to human questions have a kindred character, and bear a certain stamp of homogeneity, which is vaguely present to our minds when we speak of the spirit of the age. Social speculation again, and economic research as one branch of it, is both through its philosophic method and through its doctrine under the influence of those simpler sciences which in the order of development precede the social, especially of the science of organic nature.

It is of the highest importance to bear in mind these several relations of economic research both to external circumstance and to other spheres of contemporary thought, because by keeping them in view we shall be led to form less absolute and therefore juster estimates of the successive phases of opinion. Instead of merely praising or blaming these according to the degrees of their accordance with a predetermined standard of doctrine, we shall view them as elements in an ordered series, to be studied mainly with respect to their filiation, their opportuneness, and their influences. We shall not regard each new step in this theoretic development as implying an unconditional negation of earlier views, which often had a relative justification, resting, as they did, on a real, though narrower, basis of experience, or assuming the existence of a different social order. Nor shall we consider all the theoretic positions now occupied as definitive; for the practical system of life which they tacitly assume is itself susceptible of change, and destined, without doubt, more or less to undergo it. Within the limits of a sketch like the present these considerations cannot be fully worked out; but an effort will be made to keep them in view, and to mark the relations here indicated, wherever their influence is specially important or interesting.

The particular situation and tendencies of the several thinkers whose names are associated with economic doctrines have, of course, modified in a greater or less degree the spirit or form of those doctrines. Their relation to special predecessors, their native temperament, their early training, their religious prepossessions and political partialities, have all had their effects. To these we shall in some remarkable instances direct attention; but, in the main, they are, for our present purpose, secondary and subordinate. The *ensemble* must preponderate over the individual; and the constructors of theories must be regarded as organs of a common intellectual and social movement.

The history of economic inquiry is most naturally divided into the three great periods of (1) the ancient, (2) the mediæval, and (3) the modern worlds. In the two former, this branch of study could exist only in a rudimentary state. It is evident that for any considerable development of social theory two conditions must be fulfilled. First, the phenomena must have exhibited themselves on a sufficiently extended scale to supply adequate matter for observation, and afford a satisfactory basis for scientific generalizations; and, secondly, whilst the spectacle is thus provided, the spectator must have been trained for his task, and armed with the appropriate aids and instruments of research, that is to say, there must have been such a previous cultivation of the less complex sciences as

will have both furnished the necessary data of doctrine and prepared the proper methods of investigation. Sociology requires to use for its purposes theorems which belong to the domains of physics and biology, and which it must borrow from their professors; and, on the logical side, the methods which it has to employ—deductive, observational, comparative—must have been previously shaped in the cultivation of mathematics and the study of the inorganic world or of organisms less complex than the social. Hence it is plain that, though some laws or tendencies of society must have been forced on men's attention in every age by practical exigencies which could not be postponed, and though the questions thus raised must have received some empirical solution, a really scientific sociology must be the product of a very advanced stage of intellectual development. And this is true of the economic, as of other branches of social theory. We shall therefore content ourselves with a general outline of the character of economic thought in antiquity and the Middle Ages, and of the conditions which determined that character.

ANCIENT TIMES.

The Oriental Theocracies.—The earliest surviving expressions of thought on economic subjects have come down to us from the Oriental theocracies. The general spirit of the corresponding type of social life consisted in taking imitation for the fundamental principle of education, and consolidating nascent civilization by heredity of the different functions and professions, or even by a system of castes, hierarchically subordinated to each other according to the nature of their respective offices, under the common supreme direction of the sacerdotal caste. This last was charged with the traditional stock of conceptions, and their application for purposes of discipline. It sought to realize a complete regulation of human life in all its departments on the basis of this transmitted body of practical ideas. Conservation is the principal task of this social order, and its most remarkable quality is stability, which tends to degenerate into stagnation. But there can be no doubt that the useful arts were long, though slowly, progressive under this regime, from which they were inherited by the later civilizations—the system of classes or castes maintaining the degree of division of labor which had been reached in those early periods. The eminent members of the corporations which presided over the theocracies without doubt gave much earnest thought to the conduct of industry, which, unlike war, did not imperil their political pre-eminence by developing a rival class. But conceiving life as a whole, and making its regulation their primary aim, they naturally considered most the social reactions which industry is fitted to exercise. The moral side of economics is the one they habitually contemplate, or (what is not the same) the economic side of morals. They abound in those warnings against greed and the haste to be rich which religion and philosophy have in all ages seen to be necessary. They insist on honesty in mutual dealings, on just weights and measures, on the faithful observance of contracts. They admonish against the pride and arrogance apt to be generated by riches, against undue prodigality and self-indulgence, and enforce the duties of justice and beneficence towards servants and inferiors. Whilst, in accordance with the theological spirit, the personal acquisition of wealth is in general thesis represented as determined by divine wills, its dependence on individual diligence and thrift is emphatically taught. There is indeed in the fully developed theocratic systems a tendency to carry precept, which there differs little from command, to an excessive degree of minuteness—to prescribe in detail the time, the mode, and the accompaniments of almost every act of every member of the community. This system of exaggerated surveillance is connected with the union, or rather confusion, of the spiritual and

temporal powers, whence it results that many parts of the government of society are conducted by direct injunction or restraint, which at a later stage are intrusted to general intellectual and moral influences.

Greek and Roman Antiquity.—The practical economic enterprises of Greek and Roman antiquity could not, even independently of any special adverse influences, have competed in magnitude of scale or variety of resource with those of modern times. The unadvanced condition of physical science prevented a large application of the less obvious natural powers to production, or the extensive use of machinery, which has acquired such an immense development as a factor in modern industry. The imperfection of geographical knowledge and of the means of communication and transport were impediments to the growth of foreign commerce. These obstacles arose necessarily out of the mere immaturity of the industrial life of the periods in question. But more deeply rooted impediments to a vigorous and expansive economic practical system existed in the characteristic principles of the civilization of antiquity. Some writers have attempted to set aside the distinction between the ancient and modern worlds as imaginary or unimportant, and, whilst admitting the broad separation between ourselves and the theocratic peoples of the East, to represent the Greeks and Romans as standing on a substantially similar ground of thought, feeling, and action with the Western populations of our own time. But this is a serious error, arising from the same too exclusive preoccupation with the cultivated classes and with the mere speculative intellect which has often led to an undue disparagement of the Middle Ages. There is this essential difference between the spirit and life of ancient and of modern communities, that the former were organized for war, the latter during their whole history have increasingly tended to be organized for industry, as their practical end and aim. The profound influence of these different conditions on every form of human activity must never be overlooked or forgotten. With the military constitution of ancient societies the institution of slavery was essentially connected. Far from being an excrescence on the contemporary system of life, as it was in the modern West Indies or the United States of America, it was so entirely in harmony with that life that the most eminent thinkers regarded it as no less indispensable than inevitable. It does, indeed, seem to have been a temporary necessity, and on the whole, regard being had to what might have taken its place, a relative good. But it was attended with manifold evils. It led to the prevalence amongst the citizen class of a contempt for industrial occupations; every form of production, with a partial exception in favor of agriculture, was branded as unworthy of a free man—the only noble forms of activity being those directly connected with public life, whether military or administrative. Labor was degraded by the relegation of most departments of it to the servile class, above whom the free artisans were but little elevated in general esteem. The agents of production, being for the most part destitute of intellectual cultivation and excluded from any share in civic ideas, interests, or efforts, were unfitted in character as well as by position for the habits of skilful combination and vigorous initiation which the progress of industry demands. To this must be added that the comparative insecurity of life and property arising out of military habits, and the consequent risks which attended accumulation, were grave obstructions to the formation of large capitals, and to the establishment of an effective system of credit. These causes conspired with the undeveloped state of knowledge and of social relations in giving to the economic life of the ancients the limitation and monotony which contrast so strongly with the inexhaustible resource, the ceaseless expansion, and the thousandfold variety of the same activities in the modern world. It is, of course, absurd to expect in-

compatible qualities in any social system; each system must be estimated according to the work it has to do. Now the historical vocation of the ancient civilization was to be accomplished, not through industry, but through war, which was in the end to create a condition of things admitting of its own elimination and of the foundation of a regime based on pacific activity.

The Greeks.—This office was, however, reserved for Rome, as the final result of her system of conquest; the military activity of Greece, though continuous, was incoherent and sterile, except in the defence against Persia, and did not issue in the accomplishment of any such social mission. It was, doubtless, the inadequacy of the warrior life, under these conditions, to absorb the faculties of the race, that threw the energies of its most eminent members into the channel of intellectual activity, and produced a singularly rapid evolution of the æsthetic, philosophic, and scientific germs transmitted by the theocratic societies.

In the *Works and Days* of Hesiod, we find an order of thinking in the economic sphere very similar to that of the theocracies. With a recognition of the divine disposing power, and traditional rules of sacerdotal origin, is combined practical sagacity embodied in precept or proverbial saying. But the development of abstract thought, beginning from the time of Thales, soon gives to Greek culture its characteristic form, and marks a new epoch in the intellectual history of mankind.

The movement was now begun, destined to mould the whole future of humanity, which, gradually sapping the old hereditary structure of theological convictions, tended to the substitution of rational theories in every department of speculation. The eminent Greek thinkers, while taking a deep interest in the rise of positive science, and most of them studying the only science—that of geometry—then assuming its definitive character, were led by the social exigencies which always powerfully affect great minds to study with special care the nature of man and the conditions of his existence in society. These studies were indeed essentially premature; a long development of the inorganic and vital sciences was necessary before sociology or morals could attain their normal constitution. But by their prosecution amongst the Greeks a noble intellectual activity was kept alive, and many of those partial lights obtained for which mankind cannot afford to wait. Economic inquiries, along with others, tended towards rationality; Plutus was dethroned and terrestrial substituted for supernatural agencies. But such inquiries, resting on no sufficiently large basis of practical life, could not attain any considerable results. The military constitution of society, and the existence of slavery, which was related to it, leading, as has been shown, to a low estimate of productive industry, turned away the habitual attention of thinkers from that domain. On the other hand, the absorption of citizens in the life of the state, and their preoccupation with party struggles, brought questions relating to politics, properly so called, into special prominence. The principal writers on social subjects are therefore almost exclusively occupied with the examination and comparison of political constitutions, and with the search after the education best adapted to train the citizen for public functions. And we find, accordingly, in them no systematic or adequate handling of economic questions—only some happy ideas and striking partial anticipations of later research.

In their thinking on such questions, as on all sociological subjects, the following general features are observable.

1. The individual is conceived as subordinated to the state, through which alone his nature can be developed and completed, and to the maintenance and service of which all his efforts must be directed. The great aim of all political thought is the formation of

good citizens; every social question is studied primarily from the ethical and educational point of view. The citizen is not regarded as a producer, but only as a possessor, of material wealth; and this wealth is not esteemed for its own sake or for the enjoyments it procures, but for the higher moral and public aims to which it may be made subservient.

2. The state, therefore, claims and exercises a controlling and regulating authority over every sphere of social life, including the economic, in order to bring individual action into harmony with the good of the whole.

3. With these fundamental notions is combined a tendency to attribute to institutions and to legislation an unlimited efficacy, as if society had no spontaneous tendencies, but would obey any external impulse, if impressed upon it with sufficient force and continuity.

Every eminent social speculator had his ideal state, which approximated to or diverged from the actual or possible, according to the degree in which a sense of reality and a positive habit of thinking characterized the author.

The most celebrated of these ideal systems is that of Plato. In it the Greek idea of the subordination of the individual to the state appears in its most extreme form. In that class of the citizens of his republic who represent the highest type of life, community of property and of wives is established, as the most effective means of suppressing the sense of private interest, and consecrating the individual entirely to the public service. It cannot perhaps be truly said that his scheme was incapable of realization in an ancient community favorably situated for the purpose. But it would soon be broken to pieces by the forces which would be developed in an industrial society. It has, however, been the fruitful parent of modern Utopias, specially attractive as it is to minds in which the literary instinct is stronger than the scientific judgment, in consequence of the freshness and brilliancy of Plato's exposition and the unrivalled charm of his style. Mixed with what we should call the chimerical ideas in his work, there are many striking and elevated moral conceptions, and, what is more to our present purpose, some just economic analyses. In particular, he gives a correct account of the division and combination of employments, as they naturally arise in society. The foundation of the social organization he traces, perhaps, too exclusively to economic grounds, not giving sufficient weight to the disinterested social impulses in men which tend to draw and bind them together. But he explains clearly how the different wants and capacities of individuals demand and give rise to mutual services, and how, by the restriction of each to the sort of occupation to which, by his position, abilities, and training, he is best adapted, everything needful for the whole is more easily and better produced or effected. In the spirit of all the ancient legislators he desires a self-sufficing state, protected from unnecessary contacts with foreign populations, which might tend to break down its internal organization or to deteriorate the national character. Hence he discountenances foreign trade, and with this view removes his ideal city to some distance from the sea. The limits of its territory are rigidly fixed and the population is restricted by the prohibition of early marriages, by the exposure of infants, and by the maintenance of a determinate number of individual lots of land in the hands of the citizens who cultivate the soil. These precautions are inspired more by political and moral motives than by the Malthusian fear of failure of subsistence. Plato aims, as far as possible, at equality of property amongst the families of the community which are engaged in the immediate prosecution of industry. This last class, as distinguished from the governing and military classes, he holds, according to the spirit of his age, in but little esteem; he regards their habitual occupations as tending to the degradation of the mind and the enfeeblement of the body, and rendering those who follow them unfit for the higher duties of men and citizens. The lowest forms of labor he would commit to foreigners and slaves. Again in the spirit of ancient theory, he wishes (*Legg.*, v. 12) to banish the precious metals, as far as practicable, from use in internal commerce, and forbids the lending of money on interest, leaving indeed to the free will of the debtor even the repayment of the capital of the loan. All economic dealings he subjects to active control on the part of the Government, not merely to prevent violence and fraud, but to check the growth of luxurious habits, and secure to the population of the state a due supply of the necessities and comforts of life.

Contrasted with the exaggerated idealism of Plato is the somewhat limited but eminently practical genius of Xenophon. In him the man of action predominates, but he has also a large element of the speculative tendency and talent of the Greek. His treatise entitled *Œconomies* is well worth reading for the interesting and animated picture it presents of some aspects of contemporary life, and is justly praised by Sismondi for the spirit of mild philanthropy and tender piety which breathes through it. But it scarcely passes beyond the bounds of domestic economy, though within that limit its author exhibits much sound sense and sagacity. His precepts for the judicious conduct of private property do not concern us here, nor his wise suggestions for the government of the family and its dependants. Yet it is in this narrower sphere and in general in the concrete domain that his chief excellence lies; to economics in their wider aspects he does not contribute much. He shares the ordinary preference of his fellow countrymen for agriculture over other employments, and is, indeed, enthusiastic in his praises of it as developing patriotic and religious feeling and a respect for property, as the best preparation for military life, and as leaving sufficient time and thought disposable to admit of considerable intellectual and political activity. Yet his practical sense leads him to attribute greater importance than most other Greek writers to manufactures, and still more to trade, to enter more largely on questions relating to their conditions and development, and to bespeak for them the countenance and protection of the state. Though his views on the nature of money are vague and in some respects erroneous, he sees that its export in exchange for commodities will not impoverish the community. He also insists on the necessity, with a view to a flourishing commerce with other countries, of peace, of a courteous and respectful treatment of foreign traders, and of a prompt and equitable decision of their legal suits. The institution of slavery he of course recognizes and does not disapprove; he even recommends, for the increase of the Attic revenues, the hiring out of slaves by the state for labor in the mines, after branding them to prevent their escape, the number of slaves being constantly increased by fresh purchases out of the gains of the enterprise.

Almost the whole system of Greek ideas up to the time of Aristotle is represented in his encyclopaedic construction. Mathematical and astronomical science was largely developed at a later stage, but in the field of social studies no higher point was ever attained by the Greeks than is reached in the writings of this great thinker. Both his gifts and his situation eminently favored him in the treatment of these subjects. He combined in rare measure a capacity for keen observation with generalizing power, and sobriety of judgment with ardor for the public good. All that was original or significant in the political life of Hellas had run its course before his time or under his own eyes, and he had thus a large basis of varied experience on which to ground his conclusions. Standing outside the actual movement of contemporary public life, he occupied the position of thoughtful spectator and impartial judge. He could not indeed, for reasons already stated, any more than other Greek speculators, attain a fully normal attitude in these researches. Nor could he pass beyond the sphere of what is now called statical sociology; the idea of laws of the historical development of social phenomena he scarcely apprehended, except in some small degree in relation to the succession of political forms. But there is to be found in his writings a remarkable body of sound and valuable thoughts on the constitution and working of the social organism. The special notices of economic subjects are neither so numerous nor so detailed as we should desire. Like all the Greek thinkers, he recognizes but one doctrine of the state, under which ethics, politics proper, and economics take their place as departments bearing to each other a very close relation, and having indeed their lines of demarcation from each other not very distinctly marked. When wealth comes under consideration, it is studied not as an end in itself, but with a view to the higher elements and ultimate aims of the collective life.

The origin of society he traces, not to economic necessities, but to natural social impulses in the human constitution. The nature of the social union, when thus established, being determined by the partly spontaneous partly systematic combination of diverse activities, he respects the independence of the latter whilst seeking to effect their convergence. He therefore opposes himself to the suppression of personal freedom and initiative, and the excessive subordination of the individual to the state, and rejects the community of property and wives proposed by Plato for his governing class. The principle of private property he regards as deeply rooted in man, and the evils which are alleged to result from the corresponding social ordinance he

thinks ought really to be attributed either to the imperfections of our nature or to the vices of other public institutions. Community of goods must, in his view, tend to neglect of the common interest and to the disturbance of social harmony.

Of the several classes which provide for the different wants of the society, those who are occupied directly with its material needs—the immediate cultivators of the soil, the mechanics and artificers—are excluded from any share in the government of the state, as being without the necessary leisure and cultivation, and apt to be debased by the nature of their occupations. In a celebrated passage he propounds a theory of slavery, in which it is based on the universality of the relation between command and obedience, and on the natural division by which the ruling is marked off from the subject race. He regards the slave as having no independent will, but as an “animated tool” in the hands of his master; and in his subjection to such control, if only it be intelligent, Aristotle holds that the true well-being of the inferior as well as of the superior is to be found. This view, so shocking to our modern sentiment, is of course not personal to Aristotle; it is simply the theoretic presentation of the facts of Greek life, in which the maintenance of a body of citizens pursuing the higher culture and devoted to the tasks of war and government was founded on the systematic degradation of a wronged and despised class, excluded from all the higher offices of human beings and sacrificed to the maintenance of a special type of society.

The methods of economic acquisition are divided by Aristotle into two, one of which has for its aim the appropriation of natural products and their application to the material uses of the household; under this head come hunting, fishing, cattle-rearing, and agriculture. With this “natural economy,” as it may be called, is, in some sense, contrasted the other method to which Aristotle gives the name of “chrematistic,” in which an active exchange of products goes on, and money comes into operation as its medium and regulator. A certain measure of this “money economy,” as it may be termed in opposition to the preceding and simpler form of industrial life, is accepted by Aristotle as a necessary extension of the latter, arising out of increased activity of intercourse, and satisfying real wants. But its development on the great scale, founded on the thirst for enjoyment and the unlimited desire of gain, he condemns as unworthy and corrupting. Though his views on this subject appear to be principally based on moral grounds, there are some indications of his having entertained the erroneous opinion held by the physiocrats of the 18th century, that agriculture alone (with the other branches of natural economy) is truly productive, whilst the other kinds of industry, which either modify the products of nature or distribute them by way of exchange, however convenient and useful they may be, make no addition to the wealth of the community.

He rightly regards money as altogether different from wealth, illustrating the difference by the story of Midas. And he seems to have seen that money, though its use rests on a social convention, must be composed of a material possessing an independent value of its own. That his views on capital were indistinct appears from his famous argument against interest on loans, which is based on the idea that money is barren and cannot produce money.

Like the other Greek social philosophers, Aristotle recommends to the care of Governments the preservation of a due proportion between the extent of the civic territory and its population, and relies on pre-nuptial continence, late marriages, and the prevention or destruction of births for the due limitation of the number of citizens, the insufficiency of the latter being dangerous to the independence and its superabundance to the tranquillity and good order of the state.

The Romans.—Notwithstanding the eminently practical, realistic, and utilitarian character of the Romans, there was no energetic exercise of their powers in the economic field; they developed no large and many-sided system of production and exchange. Their historic mission was military and political, and the national energies were mainly devoted to the public service at home and in the field. To agriculture, indeed, much attention was given from the earliest times, and on it was founded the existence of the hardy population which won the first steps in the march to universal dominion. But in the course of their history the cultivation of the soil by a native yeomanry gave place to the introduction on a great scale of slave laborers, acquired by their foreign conquests; and for the small properties of the earlier period were substituted

the vast estates—the *latifundia*—which, in the judgment of Pliny, were the ruin of Italy. The industrial arts and commerce (the latter, at least when not conducted on a great scale) they regarded as ignoble pursuits, unworthy of free citizens; and this feeling of contempt was not merely a prejudice of narrow or uninstructed minds, but was shared by Cicero (*De Off.* i. 42) and others among the most liberal spirits of the nation. As might be expected from the want of speculative originality among the Romans, there is little evidence of serious theoretic inquiry on economic subjects. Their ideas on these as on other social questions were for the most part borrowed from the Greek thinkers. Such traces of economic thought as do occur are to be found in (1) the philosophers, (2) the writers *de re rustica*, and (3) the jurists. It must, however, be admitted that many of the passages in these authors referred to by those who assert the claim of the Romans to a more prominent place in the history of the science often contain only obvious truths or vague generalities.

In the philosophers, whom Cicero, Seneca, and the elder Pliny sufficiently represent (the last indeed being rather a learned encyclopædist or polyhistor than a philosopher), we find a general consciousness of the decay of industry, the relaxation of morals, and the growing spirit of self-indulgence amongst their contemporaries, who are represented as deeply tainted with the imported vices of the conquered nations. This sentiment, both in these writers and in the poetry and miscellaneous literature of their times, is accompanied by a half-factitious enthusiasm for agriculture and an exaggerated estimate of country life and of early Roman habits, which are principally, no doubt, to be regarded as a form of protest against the evils of the present, and, from this point of view, remind us of the declamations of Rousseau in a not dissimilar age. But there is little of large or just thinking on the economic evils of the time and their proper remedies. Pliny, still further in the spirit of Rousseau, is of opinion that the introduction of gold as a medium of exchange was a thing to be deplored, and that the age of barter was preferable to that of money. He expresses views on the necessity of preventing the efflux of money similar to those of the modern mercantile school—views which Cicero also, though not so clearly, appears to have entertained. Cato, Varro, and Columella concern themselves more with the technical precepts of husbandry than with the general conditions of industrial success and social well-being. But the two last named have the great merit of having seen and proclaimed the superior value of free to slave labor, and Columella is convinced that to the use of the latter the decline of the agricultural economy of the Romans was in a great measure to be attributed. These three writers agree in the belief that it was chiefly by the revival and reform of agriculture that the threatening inroads of moral corruption could be stayed, the old Roman virtues fostered, and the foundations of the commonwealth strengthened. Their attitude is thus similar to that of the French physiocrats invoking the improvement and zealous pursuit of agriculture alike against the material evils and the social degeneracy of their time. The question of the comparative merits of the large and small systems of cultivation appears to have been much discussed in the old Roman, as in the modern European world; Columella is a decided advocate of the *petite culture*. The jurists were led by the coincidence which sometimes takes place between their point of view and that of economic science to make certain classifications and establish some more or less refined distinctions which the modern economists have either adopted from them or used independently. They appear also (though this has been disputed, Neri and Carli maintaining the affirmative, Pagnini the negative) to have had correct notions of the nature of money as having necessarily a value of its own, determined by economic conditions, and therefore incapable of being impressed upon it by convention or arbitrarily altered by public authority. But in general we find in these writers, as might be expected, not so much the results of independent thought as documents illustrating the facts of Roman economic life, and the historical policy of the nation with respect to economic subjects. From the latter point of view they are of much interest; and by the information they supply as to the course of legislation relating to property generally, to sumptuary control, to the restrictions imposed on spendthrifts, to slavery, to the encouragement of population, and the like, they give us much clearer insight than we should otherwise possess into influences long potent in the history of Rome and of the

Western world at large. But, as it is with the more limited field of systematic thought on political economy that we are here occupied, we cannot enter into these subjects. One matter, however, ought to be adverted to, because it was not only repeatedly dealt with by legislation, but is treated more or less fully by all Roman writers of note, namely, the interest on money loans. The rate was fixed by the laws of the Twelve Tables; but lending on interest was afterwards (B.C. 341) entirely prohibited by the Genucian Law. In the legislation of Justinian, rates were sanctioned varying from four to eight per cent. according to the nature of the case, the latter being fixed as the ordinary mercantile rate, whilst compound interest was forbidden. The Roman theorists almost without exception disapprove of lending on interest altogether. Cato, as Cicero tells us, thought it as bad as murder ("Quid fenerari? Quid hominem occidere?" *De Off.* ii. 25); and Cicero, Seneca, Pliny, Columella all join in condemning it. It is not difficult to see how in early states of society the trade of money-lending becomes, and not unjustly, the object of popular odium; but that these writers, at a period when commercial enterprise had made such considerable progress, should continue to reprobate it argues very imperfect or confused ideas on the nature and functions of capital. It is probable that practice took little heed either of these speculative ideas or of legislation on the subject, which experience shows can always be easily evaded. The traffic in money seems to have gone on all through Roman history, and the rate to have fluctuated according to the condition of the market.

Looking back on the history of ancient economic speculation, we see that, as might be anticipated *a priori*, the results attained in that field by the Greek and Roman writers were very scanty. As Dühring has well remarked, the questions with which the science has to do were regarded by the ancient thinkers rather from their political than their properly economic side. This we have already pointed out with respect to their treatment of the subject of population, and the same may be seen in the case of the doctrine of the division of labor, with which Plato and Aristotle are in some degree occupied. They regard that principle as a basis of social classification, or use it in showing that society is founded on a spontaneous co-operation of diverse activities. From the strictly economic point of view, there are three important propositions which can be enunciated respecting that division: (1) that its extension within any branch of production makes the products cheaper; (2) that it is limited by the extent of the market; and (3) that it can be carried farther in manufactures than in agriculture. But we shall look in vain for these propositions in the ancient writers; the first alone might be *inferred* from their discussions of the subject. It has been the tendency especially of German scholars to magnify unduly the extent and value of the contributions of antiquity to economic knowledge. The Greek and Roman authors ought certainly not to be omitted in any account of the evolution of this branch of study. But it must be kept steadily in view that we find in them only first hints or rudiments of general economic truths, and that the science is essentially a modern one. We shall indeed see hereafter that it could not have attained its definitive constitution before our own time.

MIDDLE AGES.

The Middle Ages (400–1300 A.D.) form a period of great significance in the economic, as in the general, history of Europe. They represent a vast transition, in which the germs of a new world were deposited, but in which little was fully elaborated. There is scarcely anything in the later movement of European society which we do not find there, though as yet, for the most part, crude and undeveloped. The mediæval period was the object of contemptuous depreciation on the part of the liberal schools of the last century, principally because it contributed so little to literature. But there are things more important to mankind than literature; and the great men of the Middle Ages had enough to do in other fields to occupy their utmost energies. The development of the Catholic institutions and

the gradual establishment and maintenance of a settled order after the dissolution of the Western empire absorbed the powers of the thinkers and practical men of several centuries. The first mediæval phase, from the commencement of the 5th century to the end of the 7th, was occupied with the painful and stormy struggle towards the foundation of the new ecclesiastical and civil system; three more centuries were filled with the work of its consolidation and defence against the assaults of nomad populations; only in the final phase, during the 11th, 12th, and 13th centuries, when the unity of the West was founded by the collective action against impending Moslem invasion, did it enjoy a sufficiently secure and stable existence to exhibit its essential character, and produce its noblest personal types. The elaboration of feudalism was, indeed, in progress during the whole period, showing itself in the decomposition of power and the hierarchical subordination of its several grades, the movement being only temporarily suspended during the second phase by the necessary defensive concentration under Charlemagne. But not before the first century of the last phase was the feudal system fully constituted. In like manner, only in the final phase could the effort of Catholicism after a universal discipline be carried out on the great scale—an effort forever admirable, though necessarily on the whole unsuccessful.

No large or varied economic activity was possible under the ascendancy of feudalism. That organization, as has been abundantly shown by philosophical historians, was indispensable for the preservation of order and for public defence, and contributed important elements to general civilization. But, whilst recognizing it as opportune and relatively beneficent, we must not expect from it advantages inconsistent with its essential nature and historical office. The class which predominated in it was not sympathetic with industry, and held the handicrafts in contempt, except those subservient to war or rural sports. The whole practical life of the society was founded on territorial property; the wealth of the lord consisted in the produce of his lands and the dues paid to him in kind; this wealth was spent in supporting a body of retainers whose services were repaid by their maintenance. There could be little room for manufactures, and less for commerce; and agriculture was carried on with a view to the wants of the family, or at most of the immediate neighborhood, not to those of a wider market. The economy of the period was therefore simple, and, in the absence of special motors from without, unprogressive.

In the latter portion of the Middle Ages several circumstances came into action which greatly modified these conditions. The crusades undoubtedly produced a powerful economic effect by transferring in many cases the possessions of the feudal chiefs to the industrious classes, whilst by bringing different nations and races into contact, by enlarging the horizon and widening the conceptions of the populations, as well as by affording a special stimulus to navigation, they tended to give a new activity to international trade. The independence of the towns and the rising importance of the burgher class supplied a counterpoise to the power of the land aristocracy; and the strength of these new social elements was increased by the corporate constitution given to the urban industries, the police of the towns being also founded on the trade guilds, as that of the country districts was on the feudal relations. The increasing demand of the towns for the products of agriculture gave to the prosecution of that art a more extended and speculative character; and this again led to improved methods of transport and communication. But the range of commercial enterprise continued everywhere narrow, except in some favored centres, such as the Italian republics, in which, however, the growth of the normal habits of industrial life was impeded or perverted

by military ambition, which was not, in the case of those communities, checked as it was elsewhere by the pressure of an aristocratic class.

Every great change of opinion on the destinies of man and the guiding principles of conduct must react on the sphere of material interests; and the Catholic religion had a powerful influence on the economic life of the Middle Ages. Christianity inculcates, perhaps, no more effectively than the older religions the special economic virtues of industry, thrift, fidelity to engagements, obedience to lawful authority; but it brought out more forcibly and presented more persistently the higher aims of life, and so produced a more elevated way of viewing the different social relations. It purified domestic life, a reform which has the most important economic results. It taught the doctrine of fundamental human equality, heightened the dignity of labor, and preached with quite a new emphasis the obligations of love, compassion, and forgiveness, and the claims of the poor. The constant presentation to the general mind and conscience of these ideas, the dogmatic bases of which were scarcely as yet assailed by skepticism, must have had a powerful effect in moralizing life. But to the influence of Christianity as a moral doctrine was added that of the church as an organization, charged with the application of that doctrine to men's daily transactions. Besides the teachings of the sacred books, there was a mass of ecclesiastical legislation providing specific prescriptions for the conduct of the faithful. And this legislation dealt with the economic as with other provinces of social activity. In the *Corpus Juris Canonici*, which condenses the result of centuries of study and effort, along with much else is set out what we may call the Catholic economic theory, if we understand by theory, not a reasoned explanation of phenomena, but a body of ideas leading to prescriptions for the guidance of conduct. Life is here looked at from the point of view of spiritual interests; the aim is to establish and maintain amongst men a true kingdom of God.

The canonists are friendly to the notion of a community of goods from the side of sentiment ("Dulcissima rerum possessio communis est"), though they regard the distinction of *meum* and *tuum* as an institution necessitated by the fallen state of man. In cases of need the public authority is justified in re-establishing *pro hac vice* the primitive community. The care of the poor is not a matter of free choice; the relief of their necessities is *debitum legale*. *Avaritia* is idolatry; *cupiditas*, even when it does not grasp at what is another's, is the root of all evil, and ought to be not merely regulated but eradicated. Agriculture and handiwork are viewed as legitimate modes of earning food and clothing; but trade is regarded with disfavor, because it was held almost certainly to lead to fraud: of agriculture it was said, "Deo non displicet"; but of the merchant, "Deo placere non potest." The seller was bound to fix the price of his wares, not according to the market rate, as determined by supply and demand, but according to their intrinsic value (*justum pretium*). He must not conceal the faults of his merchandise, nor take advantage of the need or ignorance of the buyer to obtain from him more than the fair price. Interest on money is forbidden; the prohibition of usury is, indeed, as Roscher says, the centre of the whole canonistic system of economy, as well as the foundation of a great part of the ecclesiastical jurisdiction. The question whether a transaction was or was not usurious turning mainly on the intentions of the parties; the innocence or blameworthiness of dealings in which money was lent became rightfully a subject of determination for the church, either by her casuists or in her courts.

The foregoing principles point towards a noble ideal, but by their ascetic exaggeration they worked in some directions as an impediment to industrial progress. Thus, whilst, with the increase of production, a greater

division of labor and a larger employment of borrowed capital naturally followed, the laws on usury tended to hinder this expansion. Hence they were undermined by various exceptions, or evaded by fictitious transactions. These laws were in fact dictated by, and adapted to, early conditions—to a state of society in which money loans were commonly sought either with a view to wasteful pleasures or for the relief of such urgent distress as ought rather to have been the object of Christian beneficence. But they were quite unsuited to a period in which capital was borrowed for ends useful to the public, for the extension of enterprise and the employment of labor. The absolute theological spirit in this, as in other instances, could not admit the modification in rules of conduct demanded by a new social situation; and vulgar good sense better understood what were the fundamental conditions of industrial life.

When the intellectual activity previously repressed by the more urgent claims of social preoccupations tended to revive towards the close of the mediæval period, the want of a rational appreciation of the whole of human affairs was felt, and was temporarily met by the adoption of the results of the best Greek speculation. Hence we find in the writings of St. Thomas Aquinas the political and economic doctrines of Aristotle reproduced with a partial infusion of Christian elements. His adherence to his master's point of view is strikingly shown by the fact that he accepts (at least if he is the author of the *De Regimine Principum*) his theory of slavery, though by the action of the forces of his own time the last relics of that institution were being eliminated from European society.

This great change—the enfranchisement of the working classes—was the most important practical outcome of the Middle Ages. The first step in this movement was the transformation of slavery, properly so called, into serfdom. The latter is, by its nature, a transitory condition. The serf was bound to the soil, had fixed domestic relations, and participated in the religious life of the society; and the tendency of all his circumstances, as well as of the opinions and sentiments of the time, was in the direction of liberation. This issue was, indeed, not so speedily reached by the rural as by the urban workman. Already in the second phase serfdom is abolished in the cities and towns, whilst agricultural serfdom does not disappear before the third. The latter revolution is attributed by Adam Smith to the operation of selfish interests, that of the proprietor on the one hand, who discovered the superior productiveness of cultivation by free tenants, and that of the sovereign on the other, who, jealous of the great lords, encouraged the encroachments of the vassals on their authority. But that the church deserves a share of the merit seems beyond doubt—moral impulses, as often happens, conspiring with political and economic motives. The serfs were treated best on the ecclesiastical estates, and the members of the priesthood, both by their doctrine and by their situation since the Northern conquests, were constituted patrons and guardians of the oppressed or subject classes.

Out of the liberation of the serfs rose the first lineaments of the hierarchical constitution of modern industry in the separation between the entrepreneurs and the workers. The personal enfranchisement of the latter, stimulating activity and developing initiative, led to accumulations, which were further promoted by the establishment of order and good government by the civic corporations which grew out of the enfranchisement. Thus an active capitalist class came into existence. It appeared first in commerce, the inhabitants of the trading cities importing expensive luxuries from foreign countries, or the improved manufactures of richer communities, for which the great proprietors gladly exchanged the raw produce of their lands. In performing the office of carriers, too, be-

tween different countries, these cities had an increasing field for commercial enterprise. At a later period, as Adam Smith has shown, commerce promoted the growth of manufactures, which were either produced for foreign sale, or made from foreign materials, or imitated from the work of foreign artificers. But the first important development of handicrafts in modern Europe belongs to the 14th and 15th centuries, and the rise of manufacturing entrepreneurs is not conspicuous within the Middle Ages properly so called. Agriculture, of course, lags behind; though the feudal lords tend to transform themselves into directors of agricultural enterprise, their habits and prejudices retard such a movement, and the advance of rural industry proceeds slowly. It does, however, proceed, partly by the stimulation arising from the desire to procure the finer objects of manufacture imported from abroad or produced by increased skill at home, partly by the expenditure on the land of capital amassed in the prosecution of urban industries.

Some of the trade corporations in the cities appear to have been of great antiquity; but it was in the 13th century that they rose to importance by being legally recognized and regulated. These corporations have been much too absolutely condemned by most of the economists, who insist on applying to the Middle Ages the ideas of the 18th and 19th centuries. They were, it is true, unfitted for modern times, and it was necessary that they should disappear; their existence indeed was quite unduly prolonged. But they were at first in several respects highly beneficial. They were a valuable rallying point for the new industrial forces, which were strengthened by the rise of the *esprit de corps* which they fostered. They improved technical skill by the precautions which were taken for the solidity and finished execution of the wares produced in each locality, and it was with a view to the advancement of the industrial arts that St. Louis undertook the better organization of the trades of Paris. The corporations also encouraged good moral habits through the sort of spontaneous surveillance which they exercised, and they tended to develop the social sentiment within the limits of each profession, in times when a larger public spirit could scarcely yet be looked for.

MODERN TIMES.

The close of the Middle Ages, as Comte has shown, must be placed at the end, not of the 15th, but of the 13th century. The modern period, which then began, is filled by a development exhibiting three successive phases, and issuing in the state of things which characterizes our own epoch. During the 14th and 15th centuries the Catholic-feudal system was breaking down by the mutual conflicts of its own official members, whilst the constituent elements of a new order were rising beneath it. On the practical side the antagonists matched against each other were the crown and the feudal chiefs; and these rival powers sought to strengthen themselves by forming alliances with the towns and the industrial forces they represented. The movements of this phase can scarcely be said to find an echo in any contemporary economic literature. In the second phase of the modern period, which opens with the beginning of the 16th century, the spontaneous collapse of the mediæval structure is followed by a series of systematic assaults which still further disorganize it. During this phase the central temporal power, which has made a great advance in stability and resources, lays hold of the rising elements of manufactures and commerce, and seeks, whilst satisfying the popular enthusiasm for their promotion, to use them for political ends, and make them subserve its own strength and splendor by furnishing the treasure necessary for military success. With this practical effort and the social tendencies on which it rests the mercantile school of political economy, which then obtains a spontaneous ascendancy, is in close relation. Whilst

partially succeeding in the policy we have indicated, the European Governments yet on the whole necessarily fail, their origin and nature disqualifying them for the task of guiding the industrial movement; and the discredit of the spiritual power, with which most of them are confederate, further weakens and undermines them. In the last phase, which coincides approximately with the 18th century, the tendency to a completely new system, both temporal and spiritual, becomes decisively pronounced, first in the philosophy and general literature of the period, and then in the great French explosion. The universal critical doctrine, which had been announced by the Protestantism of the previous phase, and systematized in England towards the close of that phase, is propagated and popularized, especially by French writers. The spirit of individualism inherent in the doctrine was eminently adapted to the wants of the time, and the general favor with which the dogmas of the social contract and *laissez faire* were received indicated a just sentiment of the conditions proper to the contemporary situation of European societies. So long as a new coherent system of thought and life could not be introduced, what was to be desired was a large and active development of personal energy under no further control of the old social powers than would suffice to prevent anarchy. Governments were therefore rightly called on to abandon any effective direction of the social movement, and, as far as possible, to restrict their intervention to the maintenance of material order. This policy was, from its nature, of temporary application only; but the negative school, according to its ordinary spirit, erected what was merely a transitory and exceptional necessity into a permanent and normal law. The unanimous European movement towards the liberation of effort, which sometimes rose to the height of a public passion, had various sides, corresponding to the different aspects of thought and life; and of the economic side the French physiocrats were the first theoretic representatives on the large scale, though the office they undertook was, both in its destructive and organic provinces, more thoroughly and effectively done by Adam Smith, who must be regarded as continuing and completing their work.

It must be admitted that with the whole modern movement serious moral evils were almost necessarily connected. The general discipline which the Middle Ages had sought to institute and had partially succeeded in establishing, though on precarious bases, having broken down, the sentiment of duty was weakened along with the spirit of *ensemble* which is its natural ally, and individualism in doctrine tended to encourage egoism in action. In the economic field this result is specially conspicuous. National selfishness and private cupidity increasingly dominate; and the higher and lower industrial classes tend to separation and even to mutual hostility. The new elements—science and industry—which were gradually acquiring ascendancy bore indeed in their bosom an ultimate discipline more efficacious and stable than that which had been dissolved; but the final synthesis was long too remote, and too indeterminate in its nature, to be seen through the dispersive and seemingly incoherent growth of those elements. Now, however, that synthesis is becoming appreciable; and it is the effort towards it, and towards the practical system to be founded on it, that gives its peculiar character to the period in which we live. And to this spontaneous *nus* of society corresponds, as we shall see, a new form of economic doctrine, in which it tends to be absorbed into general sociology and subordinated to morals.

It will be the object of the following pages to verify and illustrate in detail the scheme here broadly indicated, and to point out the manner in which the respective features of the several successive modern phases find their counterpart and reflection in the historical development of economic speculation.

FIRST MODERN PHASE.

The first phase was marked, on the one hand, by the spontaneous decomposition of the mediæval system, and, on the other, by the rise of several important elements of the new order. The spiritual power became less apt as well as less able to fulfil its moral office, and the social movement was more and more left to the irregular impulses of individual energy, often enlisted in the service of ambition and cupidity. Strong Governments were formed, which served to maintain material order amidst the growing intellectual and moral disorder. The universal admission of the commons as an element in the political system showed the growing strength of the industrial forces, as did also in another way the insurrections of the working classes. The decisive prevalence of peaceful activity was indicated by the rise of the institution of paid armies—at first temporary, afterwards permanent—which prevented the interruption or distraction of labor by devoting a determinate minority of the population to martial operations and exercises. Manufactures became increasingly important; and in this branch of industry the distinction between the entrepreneur and the workers was first firmly established, whilst fixed relations between these were made possible by the restriction of military training and service to a special profession. Navigation was facilitated by the use of the mariner's compass. The art of printing showed how the intellectual movement and the industrial development were destined to be brought into relation with each other and to work towards common ends. Public credit rose in Florence, Venice, and Genoa long before Holland and England attained any great financial importance. Just at the close of the phase, the discovery of America and of the new route to the East, whilst revolutionizing the course of trade, prepared the way for the establishment of colonies, which contributed powerfully to the growing preponderance of industrial life, and pointed to its ultimate universality. It is doubtless due to the equivocal nature of the stage, standing between the mediæval and the fully characterized modern period, that on the theoretic side we find nothing corresponding to this marvellous practical ferment and expansion. The general political doctrine of Aquinas was retained, with merely subordinate modifications. The only special economic question which seems to have received particular attention was that of the nature and functions of money, the importance of which began to be felt as payments in service or in kind were discontinued, and regular systems of taxation began to be introduced.

Roscher, and after him Wolowski, have called attention to Nicole Oresme, who died bishop of Lisieux in 1382. Roscher pronounces him a great economist. His *Tractatus de Origine, Natura, Jure, et Mutationibus Monetarium* (reprinted by Wolowski, 1864) contains a theory of money which is almost entirely correct according to the views of the 19th century, and is stated with such brevity, clearness, and simplicity of language as, more than anything else, show the work to be from the hand of a master.

SECOND MODERN PHASE: MERCANTILE SYSTEM.

Throughout the first modern phase the rise of the new social forces had been essentially spontaneous; in the second they became the object of systematic encouragement on the part of Governments, which, now that the financial methods of the Middle Ages no longer sufficed, could not further their military and political ends by any other means than increased taxation, implying augmented wealth of the community. Industry thus became a permanent interest of European Governments, and even tended to become the principal object of their policy. In natural harmony with this state of facts, the mercantile system arose and grew, attaining its highest development about the middle of the 17th century.

The mercantile doctrine, stated in its most extreme

form, makes wealth and money identical, and regards it therefore as the great object of a community so to conduct its dealings with other nations as to attract to itself the largest possible share of the precious metals. Each country must seek to export the utmost possible quantity of its own manufactures, and to import as little as possible of those of other countries, receiving the difference of the two values in gold and silver. This difference is called the balance of trade, and the balance is favorable when more money is received than is paid. Governments must resort to all available expedients—prohibition of, or high duties on, the importation of foreign wares, bounties on the export of home manufactures, restrictions on the export of the precious metals—for the purpose of securing such a balance.

But this statement of the doctrine, though current in the text books, does not represent correctly the views of all who must be classed as belonging to the mercantile school. Many of the members of that school were much too clear-sighted to entertain the belief, which the modern student feels difficulty in supposing any class of thinkers to have professed, that wealth consists exclusively of gold and silver. The mercantilists may be best described, as Roscher has remarked, not by any definite economic theorem which they held in common, but by a set of theoretic tendencies, commonly found in combination, though severally prevailing in different degrees in different minds. These tendencies may be enumerated as follows: (1) towards overestimating the importance of possessing a large amount of the precious metals; (2) towards an undue exaltation (a) of foreign trade over domestic, and (b) of the industry which works up materials over that which provides them; (3) towards attaching too high a value to a dense population as an element of national strength; and (4) towards invoking the action of the state in furthering artificially the attainment of the several ends thus proposed as desirable.

If we consider the contemporary position of affairs in western Europe, we shall have no difficulty in understanding how these tendencies would inevitably arise. The discoveries in the New World had led to a large development of the European currencies. The old feudal economy, founded principally on dealings in kind, had given way before the new "money economy," and the dimensions of the latter were everywhere expanding. Circulation was becoming more rapid, distant communications more frequent, city life and movable property more important. The mercantilists were impressed by the fact that money is wealth *sui generis*, that it is at all times in universal demand, and that it puts into the hands of its possessor the power of acquiring all other commodities. The period, again, was marked by the formation of great states, with powerful governments at their head. These governments required men and money for the maintenance of permanent armies, which, especially for the religious and Italian wars, were kept up on a great scale. Court expenses, too, were more lavish than ever before, and a larger number of civil officials was employed. The royal domains and dues were insufficient to meet these requirements, and taxation grew with the demands of the monarchies. Statesmen saw that for their own political ends industry must flourish. But manufactures make possible a denser population and a higher total value of exports than agriculture; they open a less limited and more promptly extensible field to enterprise. Hence they became the object of special Governmental favor and patronage, whilst agriculture fell comparatively into the background. The growth of manufactures reacted on commerce, to which a new and mighty arena had been opened by the establishment of colonies. These were viewed simply as estates to be worked for the advantage of the mother countries, and the aim of statesmen was to make the colonial trade a new source of public revenue. Each nation, as a whole, working for its own power,

and the greater ones for predominance, they entered into a competitive struggle in the economic no less than in the political field, success in the former being indeed, by the rulers, regarded as instrumental to pre-eminence in the latter. A national economic interest came to exist, of which the Government made itself the representative head. States became a sort of artificial hothouses for the rearing of urban industries. Production was subjected to systematic regulation, with the object of securing the goodness and cheapness of the exported articles, and so maintaining the place of the nation in foreign markets. The industrial control was exercised, in part directly by the state, but largely also through privileged corporations and trading companies. High duties on imports were resorted to, at first perhaps mainly for revenue, but afterwards in the interest of national production. Commercial treaties were a principal object of diplomacy, the end in view being to exclude the competition of other nations in foreign markets, whilst in the home market as little room as possible was given for the introduction of anything but raw materials from abroad. The colonies were prohibited from trading with other European nations than the parent country, to which they supplied either the precious metals or raw produce purchased with home manufactures. It is evident that what is known as the mercantile doctrine was essentially the theoretic counterpart of the practical activities of the time, and that nations and Governments were led to it, not by any form of scientific thought, but by the force of outward circumstance, and the observation of facts which lay on the surface.

And yet, if we regard the question from the highest point of view of philosophic history, we must pronounce the universal enthusiasm of this second modern phase for manufactures and commerce to have been essentially just, as leading the nations into the main avenues of general social development. If the thought of the period, instead of being impelled by contemporary circumstances, could have been guided by sociological prevision, it must have entered with zeal upon the same path which it empirically selected. The organization of agricultural industry could not at that period make any marked progress, for the direction of its operations was still in the hands of the feudal class, which could not in general really learn the habits of industrial life, or place itself in sufficient harmony with the workers on its domains. The industry of the towns had to precede that of the country, and the latter had to be developed mainly through the indirect action of the former. And it is plain that it was in the life of the manufacturing proletariat, whose labors are necessarily the most continuous and the most social, that a systematic discipline could at a later period be first applied, to be afterwards extended to the rural populations.

That the efforts of Governments for the furtherance of manufactures and commerce were really effective towards that end is admitted by Adam Smith, and cannot reasonably be doubted, though free trade doctrinaires have often denied it. Technical skill must have been promoted by their encouragements; whilst new forms of national production were fostered by attracting workmen from other countries, and by lightening the burden of taxation on struggling industries. Communication and transport by land and sea were more rapidly improved with a view to facilitate traffic; and, not the least important effect, the social dignity of the industrial professions was enhanced relatively to that of the classes before exclusively dominant.

It has often been asked to whom the foundation of the mercantile system, in the region whether of thought or of practice, is to be attributed. But the question admits of no absolute answer. That mode of conceiving economic facts arises spontaneously in unsentient minds, and ideas suggested by it are to be found in the Greek and Latin writers. The policy which it dictates

was, as we have shown, inspired by the situation of the European nations at the opening of the modern period. Such a policy had been already in some degree practiced in the 14th and 15th centuries, thus preceding any formal exposition or defence of its speculative basis. At the commencement of the 16th century it began to exercise a widely extended influence. Charles V. adopted it, and his example contributed much to its predominance. Henry VIII. and Elizabeth conformed their measures to it. The leading states soon entered on a universal competition, in which each power brought into play all its political and financial resources for the purpose of securing to itself manufacturing and commercial preponderance. Through almost the whole of the 17th century the prize, so far as commerce was concerned, remained in the possession of Holland, Italy having lost her former ascendancy by the opening of the new maritime routes, and Spain and Germany being depressed by protracted wars and internal dissensions. The admiring envy of Holland felt by English politicians and economists appears in such writers as Raleigh, Mun, Child, and Temple; and how strongly the same spectacle acted on French policy is shown by a well-known letter of Colbert to M. de Pomponne, ambassador to the Dutch States. Cromwell, by his Navigation Act, which destroyed the carrying trade of Holland and founded the English empire of the sea, and Colbert, by his whole economic policy, domestic and international, were the chief practical representatives of the mercantile system. From the latter great statesman the Italian publicist Mengotti gave to that system the name of *Colbertismo*; but it would be an error to consider the French minister as having absolutely accepted its dogmas. He regarded his measures as temporary only, and spoke of protective duties as crutches by the help of which manufacturers might learn to walk and then throw them away. The policy of exclusions had been previously pursued by Sully, partly with a view to the accumulation of a royal treasure, but chiefly from his special enthusiasm for agriculture, and his dislike of the introduction of foreign luxuries as detrimental to the national character. Colbert's tariff of 1664 not merely simplified but considerably reduced the existing duties; the tariff of 1667 indeed increased them, but that was really a political measure directed against the Dutch. It seems certain that France owed in a large measure to his policy the vast development of trade and manufactures which so much impressed the imagination of contemporary Europe, and of which we hear so much from English writers of the time of Petty. But this policy had also undeniably its dark side. Industry was forced by such systematic regulation to follow invariable courses, instead of adapting itself to changing tastes and popular demand. Nor was it free to simplify the processes of production, or to introduce increased division of labor and improved appliances. Spontaneity, initiation, and invention were repressed or discouraged, and thus ulterior sacrificed in a great measure to immediate results. The more enlightened statesmen, and Colbert in particular, endeavored, it is true, to minimize these disadvantages by procuring, often at great expense, and communicating to the trades through inspectors nominated by the Government, information respecting improved processes employed elsewhere in the several arts; but this, though in some degree a real, was certainly on the whole, and in the long run, an insufficient compensation.

We must not expect from the writers of this stage any exposition of political economy as a whole; the publications which appeared were for the most part evoked by special exigencies and related to particular questions, usually of a practical kind, which arose out of the great movements of the time. They were in fact of the nature of counsels to the Governments of states, pointing out how best they might develop the productive powers at their disposal and increase the

resources of their respective countries. They are conceived (as List claims for them) strictly in the spirit of national economy, and cosmopolitanism is essentially foreign to them. On these monographs the mercantile theory sometimes had little influence, the problems discussed not involving its tenets. But it must in most cases be taken to be the scheme of fundamental doctrine (so far as it was ever entitled to such a description) which in the last resort underlies the writer's conclusions.

The rise of prices following on the discovery of the American mines was one of the subjects which first attracted the attention of theorists. This rise brought about a great and gradually increasing disturbance of existing economic relations, and so produced much perplexity and anxiety, which were all the more felt because the cause of the change was not understood. To this was added the loss and inconvenience arising from the debasement of the currency often resorted to by sovereigns as well as by republican states. Italy suffered most from this latter abuse, which was multiplied by her political divisions. It was this evil which called forth the work of Count Gasparo Scaruffi (*Discorso sopra le monete e della vera proporzione fra l'oro e l'argento*, 1582). In this he put forward the bold idea of a universal money,

everywhere identical in size, shape, composition, and designation. The project was, of course, premature, and was not adopted even by the Italian princes to whom the author specially appealed, but the reform is one which, doubtless, the future will see realized. Gian Donato Turbolo, master of the Neapolitan mint, in his *Discorsi e Relazioni*, 1629, protested against any tampering with the currency. Another treatise relating to the subject of money was that of the Florentine Bernardo Davanzati, otherwise known as the able translator of Tacitus, *Lezioni delle Monete*, 1588. It is a slight and somewhat superficial production, only remarkable as written with conciseness and elegance of style.

A French writer who dealt with the question of money, but from a different point of view, was Jean Bodin. In his *Réponse aux paradoxes de M. Malestroit touchant l'encherissement de toutes les choses et des monnaies*, 1568, and in his *Discours sur le haussement et diminution des monnaies*, 1578, he showed a more rational appreciation than many of his contemporaries of the causes of the revolution in prices and the relation of the variations in money to the market values of wares in general as well as to the wages of labor. He saw that the amount of money in circulation did not constitute the wealth of the community, and that the prohibition of the export of the precious metals was useless, because rendered inoperative by the necessities of trade. Bodin is no inconsiderable figure in the literary history of the epoch, and did not confine his attention to economic problems; in his *Six livres de la République*, about 1576, he studies the general conditions of the prosperity and stability of states. In harmony with the conditions of his age, he approves of absolute Governments as the most competent to ensure the security and well-being of their subjects. He enters into an elaborate defence of individual property against Plato and More, rather perhaps because the scheme of his work required the treatment of that theme than because it was practically urgent in his day, when the excesses of the Anabaptists had produced a strong feeling against communistic doctrines. He is under the general influence of the mercantilist views, and approves of energetic governmental interference in industrial matters, of high taxes on foreign manufactures and low duties on raw materials and articles of food, and attaches great importance to a dense population. But he is not a blind follower of the system; he wishes for unlimited freedom of trade in many cases, and he is in advance of his more eminent contemporary Montaigne in perceiving that the gain of one nation is not necessarily the loss of another. To the public finances, which he calls the sinews of the state, he devotes much attention and insists on the duties of the Government in respect to the right adjustment of taxation. In general he deserves the praise of steadily keeping in view the higher aims and interests of society in connection with the regulation and development of its material life.

Correct views as to the cause of the general rise of prices are also put forward by the English writer, W. S. (William Stafford), in his *Briefve Conceipte of English Policy*, published in 1581 and dedicated to Queen Elizabeth. It is in the form of a dialogue, and is written with liveliness and spirit. The author seems to have been acquainted with the writings of Bodin. He has just ideas as to the nature of money and fully understands the evils arising from a debased coinage. He describes in

detail the way in which the several interests in the country had been affected by such debasement in previous reigns, as well as by the change in the value of the precious metals. The great popular grievance of his day, the conversion of arable land into pasture, he attributes chiefly to the restrictions on the export of corn, which he desires to see abolished. But in regard to manufactures he is at the same point of view with the later mercantilists, and proposes the exclusion of all foreign wares which might as well be provided at home, and the prohibition of the export of raw materials intended to be worked up abroad.

Out of the question of money, too, arose the first remarkable German production on political economy which had an original national character and addressed the public in the native tongue. pamphlets. Duke George of the Ernestine Saxon line was inclined (1530) to introduce a debasement of the currency. A pamphlet, *Gemeine Stymmen von der Muntze*, was published in opposition to this proceeding, under the auspices of the Albertine branch, whose policy was sounder in the economic sphere no less than in that of ecclesiastical affairs. A reply appeared justifying the Ernestine project. This was followed by a rejoinder from the Albertine side. The Ernestine pamphlet is described by Roscher as ill-written, obscure, inflated, and, as might be expected from the thesis it maintained, sophistical. But it is interesting as containing a statement of the fundamental principles of the mercantile system more than one hundred years before the publication of Mun's book and forty-six before that of Bodin's *Six livres de la République*. The Albertine tracts, according to Roscher, exhibit such sound views of the conditions and evidences of national wealth, of the nature of money and trade, and of the rights and duties of governments in relation to economic action, that he regards the unknown author as entitled to a place beside Raleigh and the other English "colonial theorists" of the end of the 16th and beginning of the 17th century.

In connection with the same subject of money we meet the great name of Copernicus. His treatise *De monetæ cudendæ ratione*, 1526 (first printed in Copernicus, 1816), was written by order of King Sigismund I., and is an exposition of the principles on which it was proposed to reform the currency of the Prussian provinces of Poland. It advocates unity of the monetary system throughout the entire state, with strict integrity in the quality of the coin, and the charge of a seigniorage sufficient to cover the expenses of mintage.

Antonio Serra is regarded by some as the creator of modern political economy. He was a native of Cosenza in Calabria. His *Breve Trattato delle cause che possono fare abbondare li regni d'oro e d'argento dove non sono miniere*, 1613, was written during his imprisonment, which is believed to have been due to his having taken part in the conspiracy of Campanella for the liberation of Naples from the Spanish yoke and the establishment of a republican government. This work, long overlooked, was brought into notice in the following century by Galiani and others. Its title alone would sufficiently indicate that the author had adopted the principles of the mercantile system, and in fact in this treatise the essential doctrines of that system are expounded in a tolerably formal and consecutive manner. He strongly insists on the superiority of manufactures over agriculture as a source of national wealth, and uses in support of this view the prosperity of Genoa, Florence, and Venice, as contrasted with the depressed condition of Naples. With larger insight than many of the mercantilists exhibit, he points out the importance, towards the acquisition of wealth, not alone of favorable external conditions, but of energetic character and industrious habits in a population, as well as of a stable government and a good administration of the laws.

The first systematic treatise on our science which proceeded from a French author was the *Traité de l'Economie Politique*, published by Montchrétien Watteville, de Watteville in 1615. The use of the title, says Roscher, now for the first time given to the science, was in itself an important service, since even Bacon understood by "Economia" only the theory of domestic management. The general tendencies and aims of the period are seen in the fact that this treatise, notwithstanding the comprehensive name it bears, does not deal with agriculture at all, but only with the mechanical arts, navigation, commerce, and public finance. The author is filled with the then dominant enthusiasm for foreign trade and colonies. He advocates the control by princes of the industry of their subjects, and condemns the too great freedom, which, in his opinion to their own detriment, the Governments of Spain, Portugal, and Holland had given to trade. His book may be regarded as a formal exposition of the principles of the mercantile system for the use of Frenchmen.

A similar office was performed in England by Thomas Mun. In his two works, *A Discourse of Trade from England unto the East Indies*, 2d ed., 1621, and especially in *England's Treasure by Foreign Trade*, 1664 (posthumous), we have for the first time a clear and systematic statement of the theory of the balance of trade, as well as of the means by which, according to the author's view, a favorable balance could be secured for England. The great object of the economic policy of a state, according to him, should be so to manage its export of manufactures, its direct and carrying trade, and its customs duties as to attract to itself money from abroad. He was, however, opposed to the prohibition of the export of the precious metals in exchange for foreign wares, but on the ground, fully according with his general principles, that those wares might afterwards be re-exported and might then bring back more treasure than had been originally expended in their purchase; the first export of money might be, as he said, the seed-time, of which the ultimate receipt of a larger amount would be the harvest. He saw, too, that it is inexpedient to have too much money circulating in a country, as this enhances the prices of commodities, and so makes them less salable to foreigners, but he is favorable to the formation and maintenance of a state treasure.¹

One of the most remarkable of the modern mercantilists was Sir Josiah Child (*Brief Observations concerning Trade and the Interest of Money*, 1668, and *A New Discourse of Trade*, 1668 and 1690). He was one of those who held up Holland as a model for the imitation of his fellow-countrymen. He is strongly impressed with the importance for national wealth and well-being of a low rate of interest, which he says is to commerce and agriculture what the soil is to the body, and which he held to be the "causa ensans of all the other causes of the riches of the Dutch people." Instead of regarding such low rate as dependent on determinate conditions which should be allowed to evolve themselves spontaneously, he thinks it should be created and maintained by public authority. Child, whilst adhering to the doctrine of the balance of trade, observes that a people cannot always sell to foreigners without ever buying from them, and denies that the export of the precious metals is necessarily detrimental. He has the ordinary mercantilist partiality for a numerous population. He advocates the reservation by the mother country of the sole right of trade with her colonies, and, under certain limitations, the formation of privileged trading companies. As to the Navigation Act, he takes up a position not unlike that afterwards occupied by Adam Smith, regarding that measure much more favorably from the political than from the economic point of view. It will be seen that he is somewhat eclectic in his opinions; but he cannot properly be regarded, though some have attributed to him that character, as a precursor of the free-trade school of the 18th century.

Two other eclectics may be here mentioned, in whom just views are mingled with mercantilist prejudices—Sir William Temple and Charles Davenant. The former in his *Observations upon the United Provinces of the Netherlands*, 1672, and his *Essay on the Trade of Ireland*, 1673, has many excellent remarks on fundamental economic principles, as on the functions of labor and of saving in the production of national wealth; but he is infected with the errors of the theory of the balance of trade. He follows the lead of Raleigh and Child in urging his fellow-countrymen to imitate the example of the Dutch in their economic policy—advice which in his case was founded on his observations during a lengthened residence in Holland as ambassador to the States. Davenant, in his *Essay on the East-India Trade*, 1696-97, *Essay on the Probable Ways of making the People Gainers in the Balance of Trade*, 1699, etc., also takes up an eclectic position, combining some correct views on wealth and money with mercantilist notions on trade, and recommending Governmental restrictions on colonial commerce as strongly as he advocates freedom of exchange at home.

Whilst the mercantile system represented the prevalent form of economic thought in the 17th century, and was alone dominant in the region of practical statesmanship, there was growing up, side by side with it, a body

of opinion, different and indeed hostile in character, which was destined ultimately to drive it from the field. The new ideas were first developed in England, though it was in France that in the following century they took hold of the public mind, and became a power in politics. That they should first show themselves here, and afterwards be extended, applied, and propagated throughout Europe by French writers, belongs to the order of things according to which the general negative doctrine in morals and politics, undoubtedly of English origin, found its chief home in France, and was thence diffused in widening circles through the civilized world. In England this movement of economic thought took the shape mainly of individual criticism of the prevalent doctrines, founded on a truer analysis of facts and conceptions; in France it was penetrated with a powerful social sentiment, furnished the creed of a party, and inspired a protest against institutions and an urgent demand for practical reform.

Regarded from the theoretic side, the characteristic features of the new direction were the following. The view of at least the extreme mercantilists that national wealth depends on the accumulation of the precious metals is proved to be false, and the gifts of nature and the labor of man are shown to be its real sources. The exaggerated estimate of the importance of foreign commerce is reduced, and attention is once more turned to agriculture and the conditions of its successful prosecution. On the side of practical policy, a so-called favorable balance of trade is seen not to be the true object of a nation's or a statesman's efforts, but the procuring for the whole population in the fullest measure the enjoyment of the necessities and conveniences of life. And—what more than anything else contrasts the new system with the old—the elaborate apparatus of prohibitions, protective duties, bounties, monopolies, and privileged corporations, which the European Governments had created in the supposed interests of manufactures and trade, is denounced or deprecated as more an impediment than a furtherance, and the freedom of industry is insisted on as the one thing needful. This circle of ideas, of course, emerges only gradually, and its earliest representatives in economic literature in general apprehend it imperfectly and advocate it with reserve; but it rises steadily in importance, being more and more favored by the highest minds, and finding an increasing body of supporters amongst the intelligent public.

Some occasional traits of an economic scheme in harmony with these new tendencies are to be found in Hobbes. The *De Cive* and *Leviathan* of Hobbes. But the efficacy of that great thinker lay rather in the general philosophic field; and by systematizing, for the first time, the whole negative doctrine, he gave a powerful impulse towards the demolition of the existing social order, which was destined, as we shall see, to have momentous consequences in the economic no less than in the strictly political department of things.

A writer of no such extended range, but of much sagacity and good sense, was SIR WILLIAM PETTY (q.v.), author of a number of pieces containing germs of a sound economic doctrine. A leading thought in his writings is that "labor is the father and active principle of wealth, lands are the mother." He divides a population into two classes, the productive and the unproductive, according as they are or are not occupied in producing useful material things. The value of any commodity depends, he says, anticipating Ricardo, on the amount of labor necessary for its production. He is desirous of obtaining a universal measure of value, and chooses as his unit the average food of the cheapest kind required for a man's daily sustenance. He understands the nature of the rent of land as the excess of price over the cost of production. He disapproves of the attempt to fix by authority a maximum rate of interest, and is generally opposed to Governmental interference with the course of industry. He sees that a country requires for its exchanges a definite quantity of money and may have too much of it, and condemns the prohibition of its exportation. He holds that one only of the precious metals must be the foundation of

¹ Writers of less importance who followed the same direction were Sir Thomas Culepeper (*A Tract against the High Rate of Usury*, 1623, and *Useful Remark on High Interest*, 1641); Sir Dudley Digges (*Defence of Trade*, 1615); G. Malynes (*Consuetudo vel Lex Mercatoria*, 1622); E. Misselden (*Circle of Commerce*, 1623); Samuel Fortrey (*England's Interest and Improvement*, 1663 and 1673); and John Pollexfen (*England and India inconsistent in their Manufactures*, 1697).

the currency, the other circulating as an ordinary article of merchandise. Petty's name is specially associated with the progress of statistics, with which he was much occupied, and which he called by the name of political arithmetic. Relying on the results of such inquiries, he set himself strongly against the opinion which had been advanced by the author of *Britannia Longuena* (1680), Fortrey, Roger Coke, and other writers, that the prosperity of England was on the decline.

The most thorough-going and emphatic assertion of the free-trade doctrine against the system of prohibitions which had gained strength by the North.

Revolution was contained in Sir Dudley North's *Discourses upon Trade*, 1691. He shows that wealth may exist independently of gold or silver, its source being human industry, applied either to the cultivation of the soil or to manufactures. The precious metals, however, are one element of national wealth, and perform highly important offices. Money may exist in excess, as well as in defect, in a country; and the quantity of it required for the purposes of trade will vary with circumstances; its ebb and flow will regulate themselves spontaneously. It is a mistake to suppose that stagnation of trade arises from want of money; it must arise either from a glut of the home market, or from a disturbance of foreign commerce, or from diminished consumption caused by poverty. The export of money in the course of traffic, instead of diminishing, increases the national wealth, trade being only an exchange of superfluities. Nations are related to the world just in the same way as cities to the state or as families to the city. North emphasizes more than his predecessors the value of the home trade. With respect to the interest of capital, he maintains that it depends, like the price of any commodity, on the proportion of demand and supply, and that a low rate is a result of the relative increase of capital, and cannot be brought about by arbitrary regulations, as had been proposed by Child and others. In arguing the question of free trade, he urges that individuals often take their private interest as the measure of good and evil, and would for its sake debar others from their equal right of buying and selling, but that every advantage given to one interest or branch of trade over another is injurious to the public. No trade is unprofitable to the public; if it were, it would be given up; when trades thrive, so does the public, of which they form a part. Prices must determine themselves, and cannot be fixed by law; and all forcible interference with them does harm instead of good. No people can become rich by state regulations,—only by peace, industry, freedom, and unimpeded economic activity. It will be seen how closely North's view of things approaches to that embodied some eighty years later in Adam Smith's great work.

Locke is represented by Roscher as, along with Petty and Locke.

North, making up the "triumvirate" of eminent British economists of this period who laid the foundations of a new and more rational doctrine than that of the mercantilists. But this view of his claims seems capable of being accepted only with considerable deductions. His specially economic writings are *Considerations of the lowering of Interest and raising the value of Money*, 1691, and *Further Considerations*, 1695. Though Leibnitz declared with respect to these treatises that nothing more solid or intelligent could be said on their subject, it is difficult absolutely to adopt that verdict. Locke's spirit of sober observation and patient analysis led him indeed to some just conclusions; and he is entitled to the credit of having energetically resisted the debasement of the currency, which was then recommended by some who were held to be eminent practical authorities. But he falls into errors which show that he had not by any means completely emancipated himself from the ideas of the mercantile system. He attaches far too much importance to money as such. He says expressly that riches consist in a plenty of gold and silver, that is, as he explains, in having more in proportion of those metals than the rest of the world or than our neighbors. "In a country not furnished with mines, there are but two ways of growing rich, either conquest or commerce." Hence he accepts the doctrine of the balance of trade. He shows that the rate of interest can no more be fixed by law than the rent of houses or the hire of ships, and opposes Child's demand for legislative interference with it. But he erroneously attributed the fall of the rate which had taken place generally in Europe to the increase of the quantity of gold and silver by the discovery of the American mines. He sets too absolute a value on a numerous population, in this point agreeing with Petty. On wages he observes that the rate must be such as to cover the indispensable wants of the laborer; when the price of subsistence rises, wages must rise in a like ratio, or the working population must come on the poor-rates. The fall of the rent of land he regards as a sure sign of the decline of national wealth. "Taxes,

however contrived, and out of whose hands soever immediately taken, do, in a country where their great fund is in land, for the most part terminate upon land." In this last proposition we see a foreshadowing of the *impôt unique* of the physiocrats. Whatever may have been Locke's direct economic services, his principal importance, like that of Hobbes, lies in his general philosophic and political principles, which powerfully affected French and indeed European thought, exciting a spirit of opposition to arbitrary power, and laying the foundation of the doctrine developed in the *Contrat Social*.¹

THIRD MODERN PHASE: SYSTEM OF NATURAL LIBERTY.

Both in England and France the ruling powers had already begun to be alarmed by the subversive tendencies which appeared inherent in the modern movement, and took up in consequence an attitude of resistance. Reaction became triumphant in France during the latter half of the reign of Louis XIV. under the disastrous influence of Madame de Maintenon. In England, after the transaction of 1688, by which the government was consolidated on the double basis of aristocratic power and official orthodoxy, the state policy became not so much retrograde as stationary, industrial conquest being put forward to satisfy the middle class and wean it from the pursuit of a social renovation. In both countries there was for some time a noticeable check in the intellectual development, and Roscher and others have observed that, in economic studies particularly, the first three decades of the 18th century were a period of general stagnation, eclecticism for the most part taking the place of originality. The movement was, however, soon to be resumed, but with an altered and more formidable character. The negative doctrine, which had risen and taken a definite form in England, was diffused and popularized in France, where it became evident, even before the decisive explosion, that the only possible issue lay in a radical social transformation. The partial schools of Voltaire and Rousseau in different ways led up to a violent crisis, whilst taking little thought of the conditions of a system which could replace the old; but the more complete and organic school, of which Diderot is the best representative, looked through freedom to reorganization. Its constructive aim is shown by the design of the *Encyclopédie*,—a project, however, which could have only a temporary success, because no real synthesis was forthcoming, and this joint production of minds often divergent could possess no more than an external unity. It was with this great school that the physiocrats were specially connected; and, in common with its other members, whilst pushing towards an entire change of the existing system, they yet would gladly have avoided political demolition through the exercise of a royal dictatorship, or contemplated it only as the necessary condition of a new and better order of things. But, though marked off by such tendencies from the purely revolutionary sects, their method and fundamental ideas were negative, resting, as they did, essentially on the basis of the *jus nature*. We shall follow in detail these French developments in their special relation to economic science, and afterwards notice the corresponding movements in other European countries which showed themselves before the appearance of Adam Smith, or were at least unaffected by his influence.

¹ Minor English writers who followed the new economic direction were Lewis Roberts, *Treasure of Traffick*, 1641; Rice Vaughan, *Discourse of Coin and Coinage*, 1675; Nicholas Barbon, *Discourse concerning Coining the new money lighter*, 1696, in which some of Locke's errors were pointed out; and the author of an anonymous book entitled *Considerations on the East India Trade*, 1701. Practical questions much debated at this period were those connected with banking, on which a lengthened controversy took place, S. Lamb, W. Potter, F. Cradocke, M. Lewis, M. Godfrey, R. Murray, H. Chamberlen, and W. Paterson, founder of the Bank of England (1694), producing many pamphlets on the subject; and the management of the poor, which was treated by Locke, Sir Matthew Hale, R. Haines, T. Firmin, and others.

1. Before Adam Smith.

France.—The more liberal, as well as more rational, principles put forward by the English thinkers of the new type began, early in the 18th century, to find an echo in France, where the clearer and more vigorous intellects were prepared for their reception by a sense of the great evils which exaggerated mercantilism, serving as instrument of political ambition, had produced in that country. The impoverished condition of the agricultural population, the oppressive weight and unequal imposition of taxation, and the unsound state of the public finances had produced a general feeling of disquiet, and led several distinguished writers to protest strongly against the policy of Colbert and to demand a complete reform.

The most important amongst them was Pierre Boisguillebert, whose whole life was devoted to these controversies. In his statistical writings (*Détail de la France sous le règne présent*, 1697; *Factum de la France*, 1707) he brings out in gloomy colors the dark side of the age of Louis XIV., and in his theoretic works (*Traité de la nature et du commerce des grains*; *Dissertations sur la nature des richesses de l'argent et des tributs*; and *Essai sur la rareté de l'argent*) he appears as an earnest, even passionate antagonist of the mercantile school. He insists again and again on the fact that national wealth does not consist in gold and silver, but in useful things, foremost among which are the products of agriculture. He even goes so far as to speak of "argent criminel," which from being the slave of trade, as it ought to be, had become its tyrant. He sets the "genuinely French Sully" far above the "Italianizing Colbert," and condemns all arbitrary regulations affecting either foreign or internal commerce, especially as regards the corn trade. National wealth does not depend on Governments, whose interference does more harm than good; the natural laws of the economic order of things cannot be violated or neglected with impunity; the interests of the several classes of society in a system of freedom are identical, and those of individuals coincide with that of the state. A similar solidarity exists between different nations; in their economic dealings they are related to the world as individual towns to a nation, and not merely plenty, but peace and harmony, will result from their unfettered intercourse. Men he divides into two classes—those who do nothing and enjoy everything, and those who labor from morning to night often without earning a bare subsistence; the latter he would favor in every way. Here we catch the breath of popular sympathy which fills the social atmosphere of the 18th century. He dwells with special emphasis on the claims of agriculture, which had in France fallen into unmerited neglect, and with a view to its improvement calls for a reform in taxation. He would replace indirect taxes by taxes on income, and would restore the payment of taxes in kind, with the object of securing equality of burden and eliminating every element of the arbitrary. He has some interesting views of a general character; thus he approximates to a correct conception of agricultural rent; and he points to the order in which human wants follow each other,—those of necessity, convenience, comfort, superfluity, and ostentation succeeding in the order named, and ceasing in the inverse order to be felt as wealth decreases. The depreciating tone in which Voltaire speaks of Boisguillebert (*Siècle de Louis XIV.*, chap. 30) is certainly not justified; he had a great economic talent, and his writings contain important germs of truth. But he appears to have exerted little influence, theoretical or practical, in his own time.

The same general line of thought was followed by the illustrious Vauban in his economic tracts, especially that bearing the title of *Projet d'une dixme Royale*, 1707. He is deeply impressed with the deplorable condition of the working classes of France in his day. He urges that the aim of the Government should be the welfare of all orders of the community; that all are entitled to like favor and furtherance; that the often despised and wronged lower class is the basis of the social organization; that labor is the foundation of all wealth, and agriculture the most important species of labor; that the most essential condition of successful industry is freedom; and that all unnecessary or excessive restrictions on manufactures and commerce should be swept away. He protests in particular against the inequalities of taxation, and the exemptions and privileges enjoyed by the higher ranks. With the exception of some duties on consumption he would abolish all the existing taxes, and substitute for them a single tax on income and land, impartially applied to all classes, which he describes under the name of "Dixme

Royale," that is to say, a tenth in kind of all agricultural produce, and a tenth of money income chargeable on manufacturers and traders.

The liberal and humane spirit of Fénelon led him to aspire after freedom of commerce with foreign nations, and to preach the doctrine that the true superiority of one state over another lies in the number indeed, but also in the morality, intelligence, and industrious habits of its population. The *Télémaque*, in which these views were presented in an attractive form, was welcomed and read amongst all ranks and classes, and was thus an effective organ for the propagation of opinion.

After these writers there is a marked blank in the field of French economic thought, broken only by the *Réflexions Politiques sur les Finances et le Commerce* (1738) of Dutot, a pupil of Law, and the semi-mercantilist *Essais Politiques sur le Commerce* (1731) of Mélon, till we come to the great name of Montesquieu. The *Esprit des Loix*, so far as it deals with economic subjects, is written upon the whole from a point of view adverse to the mercantile system, especially in his treatment of money, though in his observations on colonies and elsewhere he falls in with the ideas of that system. His immortal service, however, was not rendered by any special research, but by his enforcement of the doctrine of natural laws regulating social no less than physical phenomena. There is no other thinker of importance on economic subjects in France till the appearance of the physiocrats, which marks an epoch in the history of the science.

The heads of the physiocratic school were François Quesnay (1694-1774) and Jean Claude Marie Vincent, sieur de Gournay (1712-1759). The principles of the school had been put forward in 1755 by Cantillon, a French merchant of Irish extraction (*Essai sur la nature du Commerce en général*), whose biography Jevons has elucidated, and whom he regards as the true founder of political economy; but it was in the hands of Quesnay and Gournay that they acquired a systematic form, and became the creed of a united group of thinkers and practical men, bent on carrying them into action. The members of the group called themselves "les économistes," but it is more convenient, because unambiguous, to designate them by the name "physiocrates," invented by Dupont de Nemours, who was one of their number. In this name, intended to express the fundamental idea of the school, much more is implied than the subjection of the phenomena of the social, and in particular the economic, world to fixed relations of co-existence and succession. This is the positive doctrine which lies at the bottom of all true science. But the law of nature referred to in the title of the sect was something quite different. The theological dogma which represented all the movements of the universe as directed by divine wisdom and benevolence to the production of the greatest possible sum of happiness had been transformed in the hands of the metaphysicians into the conception of a *jus nature*, a harmonious and beneficial code established by the favorite entity of these thinkers, Nature, antecedent to human institutions, and furnishing the model to which they should be made to conform. This idea, which Buckle apparently supposes to have been an invention of Hutcheson's, had come down through Roman juridical theory from the speculations of Greece. It was taken in hand by the modern negative school from Hobbes to Rousseau, and used as a powerful weapon of assault upon the existing order of society, with which the "natural" order was perpetually contrasted as offering the perfect type from which fact had deplorably diverged. The theory received different applications according to the diversity of minds or circumstances. By some it was directed against the artificial manners of the times, by others against contemporary political institutions; it was specially employed by the physiocrats in criticising the economic practice of European Governments.

The general political doctrine is as follows. Society is composed of a number of individuals all having the same natural rights. If all do not possess (as some members of the negative school maintained) equal capacities, each can at least best understand his own

interest, and is led by nature to follow it. The social union is really a contract between these individuals, the object of which is the limitation of the natural freedom of each, just so far as it is inconsistent with the rights of the others. Government, though necessary, is a necessary evil; and the governing power appointed by consent should be limited to the amount of interference absolutely required to secure the fulfilment of the contract. In the economic sphere, this implies the right of the individual to such natural enjoyments as he can acquire by his labor. That labor, therefore should be undisturbed and unfettered; and its fruits should be guaranteed to the possessor; in other words, property should be sacred. Each citizen must be allowed to make the most of his labor; and therefore freedom of exchange should be ensured, and competition in the market should be unrestricted, no monopolies or privileges being permitted to exist.

The physiocrats then proceed with the economic analysis as follows. Only those labors are truly "productive" which add to the quantity of raw materials available for the purposes of man; and the real annual addition to the wealth of the community consists of the excess of the mass of agricultural products (including, of course, metals) over their cost of production. On the amount of this "produit net" depends the well-being of the community, and the possibility of its advance in civilization. The manufacturer merely gives a new form to the materials extracted from the earth; the higher value of the object, after it has passed through his hands, only represents the quantity of provisions and other materials used and consumed in its elaboration. Commerce does nothing more than transfer the wealth already existing from one hand to another; what the trading classes gain thereby is acquired at the cost of the nation, and it is desirable that its amount should be as small as possible. The occupations of the manufacturer and merchant, as well as the liberal professions, and every kind of personal service, are "useful" indeed, but they are "sterile," drawing their income, not from any fund which they themselves create, but from the superfluous earnings of the agriculturist. Perfect freedom of trade not only rests, as we have already seen, on the foundation of natural right, but is also recommended by the consideration that it makes the "produit net," on which all wealth and general progress depend, as large as possible. "Laissez faire, laissez passer" should therefore be the motto of Governments. The revenue of the state, which must be derived altogether from this net product, ought to be raised in the most direct and simplest way,—namely, by a single impost of the nature of a land tax.

The special doctrine relating to the exclusive productiveness of agriculture arose out of a confusion between "value" on the one hand and "matter and energy" on the other. Smith and others have shown that the attempt to fix the character of "sterility" on manufactures and commerce was founded in error. And the proposal of a single *impôt territorial* falls to the ground with the doctrine on which it was based. But such influence as the school exerted depended little, if at all, on these peculiar tenets, which indeed some of its members did not hold. The effective result of its teaching was mainly destructive. It continued in a more systematic form the efforts in favor of the freedom of industry already begun in England and France. The essential historical office of the physiocrats was to discredit radically the methods followed by the European Governments in their dealings with industry. For such criticism as theirs there was, indeed, ample room: the policy of Colbert, which could be only temporarily useful, had been abusively extended and intensified; Governmental action had intruded itself into the minutest details of business, and every process of manufacture and transaction of trade was hampered by legislative restrictions. It was to be expected that the reformers should, in the spirit of the

negative philosophy, exaggerate the vices of established systems; and there can be no doubt that they condemned too absolutely the economic action of the state, both in principle and in its historic manifestations, and pushed the "laissez faire" doctrine beyond its just limits. But this was a necessary incident of their connection with the revolutionary movement, of which they really formed one wing. In the course of that movement, the primitive social contract, the sovereignty of the people, and other dogmas now seen to be untenable were habitually invoked in the region of politics proper, and had a transitory utility as ready and effective instruments of warfare. And so also in the economic sphere the doctrines of natural rights of buying and selling, of the sufficiency of enlightened selfishness as a guide in mutual dealings, of the certainty that each member of the society will understand and follow his true interests, and of the coincidence of those interests with the public welfare, though they will not bear a dispassionate examination, were temporarily useful as convenient and serviceable weapons for the overthrow of the established order. The tendency of the school was undoubtedly to consecrate the spirit of individualism, and the state of non-government. But this tendency, which may with justice be severely condemned in economists of the present time, was then excusable because inevitable. And whilst it now impedes the work of reconstruction which is for us the order of the day, it then aided the process of social demolition, which was the necessary, though deplorable, condition of a new organization.

These conclusions as to the revolutionary tendencies of the school are not at all affected by the fact that the form of government preferred by Quesnay and some of his chief followers was what they called a legal despotism, which should embrace within itself both the legislative and the executive function. The reason for this preference was that an enlightened central power could more promptly and efficaciously introduce the policy they advocated than an assembly representing divergent opinions, and fettered by constitutional checks and limitations. Turgot, as we know, used the absolute power of the crown to carry into effect some of his measures for the liberation of industry, though he ultimately failed because unsustained by the requisite force of character in Louis XVI. But what the physiocratic idea with respect to the normal method of government was appears from Quesnay's advice to the dauphin, that when he became king he should "do nothing, but let the laws rule," the laws having been of course first brought into conformity with the *jus nature*. The partiality of the school for agriculture was in harmony with the sentiment in favor of "nature" and primitive simplicity which then showed itself in so many forms in France, especially in combination with the revolutionary spirit, and of which Rousseau was the most eloquent exponent. It was also associated in these writers with a just indignation at the wretched state in which the rural laborers of France had been left by the scandalous neglect of the superior orders of society—a state of which the terrible picture drawn by La Bruyère is an indestructible record. The members of the physiocratic group were undoubtedly men of thorough uprightness, and inspired with a sincere desire for the public good, especially for the material and moral elevation of the working classes. Quesnay was physician to Louis XV., and resided in the palace at Versailles; but in the midst of that corrupt court he maintained his integrity, and spoke with manly frankness what he believed to be the truth. And never did any statesman devote himself with greater singleness of purpose or more earnest endeavor to the service of his country than Turgot, who was the principal practical representative of the school.

The publications in which Quesnay expounded his system were the following—two articles, on "Fermiers" and on "Grains," in the *Encyclopédie* of Diderot and D'Alembert (1756, 1757); a discourse on the

law of nature in the *Physiocratie* of Dupont de Nemours (1768); *Maximes générales de gouvernement économique d'un royaume agricole* (1758), and the simultaneously published *Tableau Économique avec son explication, ou Extrait des Économies Royales de Sully* (with the celebrated motto "pauvres paysans, pauvre royaume; pauvre royaume, pauvre roi"); *Dialogue sur le commerce et les travaux des artisans*; and other minor pieces. The *Tableau Économique*, though on account of its dryness and abstract form it met with little general favor, may be considered the principal manifesto of the school. It was regarded by the followers of Quesnay as entitled to a place amongst the foremost products of human wisdom, and is named by the elder Mirabeau, in a passage quoted by Adam Smith, as one of the three great inventions which have contributed most to the stability of political societies, the other two being those of writing and of money. Its object was to exhibit by means of certain formulas the way in which the products of agriculture, which is the only source of wealth, would in a state of perfect liberty be distributed among the several classes of the community (namely, the productive classes of the proprietors and cultivators of land, and the unproductive class composed of manufacturers and merchants), and to represent by other formulas the modes of distribution which take place under systems of Governmental restraint and regulation, with the evil results arising to the whole society from different degrees of such violations of the natural order. It follows from Quesnay's theoretic views that the one thing deserving the solicitude of the practical economist and the statesman is the increase of the net product; and he infers also what Smith afterwards affirmed on not quite the same ground, that the interest of the landowner is "strictly and indissolubly connected with the general interest of the society."

Jean V. Gournay, as we have seen, was regarded as one of the founders of the school, and appears to have exercised some influence even upon the formation of Quesnay's own opinions. With the exception of a translation of Sir Josiah Child, Gournay wrote nothing but memoirs addressed to ministers, which have not seen the light; but we have a full statement of his views in the *Éloge* dedicated to his memory by his illustrious friend Turgot. Whilst Quesnay had spent his youth amidst rural scenes, and had been early familiar with the labors of the field, Gournay had been bred as a merchant, and had passed from the counting-house to the office of intendant of commerce. They thus approached the study of political economy from different sides, and this diversity of their antecedents may in part explain the amount of divergence which existed between their views. Gournay softened the rigor of Quesnay's system, and brought it nearer to the truth, by rejecting what Smith calls its "capital error"—the doctrine, namely, of the unproductiveness of manufactures and commerce. He directed his efforts to the assertion and vindication of the principle of industrial liberty, and it was by him that this principle was formulated in the phrase, since so often heard for good and for evil, "Laissez faire, laissez passer." One of the earliest and most complete adherents of the physiocratic school, as well as an ardent and unwearied propagator of its doctrines, was Victor Mirabeau, whose sincere and independent, though somewhat perverse and whimsical, character is familiar to English readers through Carlyle's essay on his more celebrated son. He had expressed some physiocratic views earlier than Quesnay, but owned the latter for his spiritual father, and adopted most of his opinions, the principal difference being that he was favorable to the *petite* as opposed to the *grande* culture which latter was preferred by his chief as giving, not indeed the largest gross, but the largest net product. Mirabeau's principal writings were *Ami des Hommes, ou traité sur la population* (1756, 1760), *Théorie de l'impôt* (1760), *Les Économiques* (1769), and *Philosophie rurale, ou Économie générale et politique de l'Agriculture* (1763).

The last of these was the earliest complete exposition of the physiocratic system. Another earnest and persevering apostle of the system was Dupont de Nemours (1739-1817), known by his treatises *De l'exportation et de l'importation des grains* (1764), *De l'origine et du progrès d'une science nouvelle* (1767), *Du commerce de la Compagnie des Indes* (1767), and especially by his more comprehensive work *Physiocratie, ou Constitution naturelle du gouvernement le plus avantageux au genre humain* (1768), the title of this work gave, as has been already mentioned, a name to the school. Another formal exposition of it was produced by Mercier-Larivière, under the title *L'Ordre naturel et essentiel des sociétés politiques* (1767), a title which is interesting as embodying the idea of the *jus*

naturæ. Both he and Dupont de Nemours professed to study human communities, not only in relation to their economic, but also to their political and general social aspects; but, notwithstanding these larger pretensions, their views were commonly restricted in the main to the economic sphere; at least material considerations decidedly preponderated in their inquiries, as was naively indicated by Larivière when he said, "Property, security, liberty—these comprise the whole social order; the right of property is a tree of which all the institutions of society are branches."

The most eminent member of the group was without doubt Anne Robert Jacques Turgot (1727-1781). This is not the place to speak of his noble practical activity, first as intendant of Limoges, and afterwards for a brief period as finance minister, or of the circumstances which led to his removal from office, and the consequent failure of his efforts for the salvation of France. His economic views are explained in the introductions to his edicts and ordinances, in letters and occasional papers, but especially in his *Réflexions sur la formation et la distribution des richesses* (1766). This is a condensed but eminently clear and attractive exposition of the fundamental principles of political economy, as they were conceived by the physiocrats. It embodies, indeed, the erroneous no less than the sound doctrines of that school; but several subjects, especially the various forms of land-economy, the different employments of capital, and the legitimacy of interest, are handled in a generally just as well as striking manner; and the mode of presentation of the ideas, and the luminous arrangement of the whole, are Turgot's own. The treatise, which contains a surprising amount of matter in proportion to its length, must always retain a place among the classics of the science.

The physiocratic school never obtained much direct popular influence, even in its native country, though it strongly attracted many of the more gifted and earnest minds. Its members, writing on dry subjects in an austere and often heavy style, did not find acceptance with a public which demanded before all things charm of manner in those who addressed it. When Morellet, one of their number, entered the lists with Galiani, it was seen how *esprit* and eloquence could triumph over science, solid indeed, but clumsy in its movements. The physiocratic tenets, which were in fact partially erroneous, were regarded by many as chimerical, and were ridiculed in the contemporary literature, as, for example, the *impôt unique* by Voltaire in his *L'homme aux quarante écus*, which was directed in particular against Mercier-Larivière. It was justly objected to the group that they were too absolute in their view of things; they supposed, as Smith remarks in speaking of Quesnay, that the body politic could thrive only under one precise régime,—that, namely, which they recommended,—and thought their doctrines universally and immediately applicable in practice. They did not, as theorists, sufficiently take into account national diversities, or different stages in social development; nor did they, as politicians, adequately estimate the impediments which ignorance, prejudice, and interested opposition present to enlightened statesmanship. It is possible that Turgot himself, as Grimm suggests, owed his failure in part to the too unbending rigor of his policy and the absence of any attempt at conciliation. Be this as it may, his defeat helped to impair the credit of his principles, which were represented as having been tried and found wanting.

The physiocratic system, after guiding in some degree the policy of the Constituent Assembly, and awakening a few echoes here and there in foreign countries, soon ceased to exist as a living power; but the good elements it comprised were not lost to mankind, being incorporated into the sounder and more complete construction of Adam Smith.

Italy.—In Italy, as in the other European nations, there was little activity in the economic field during the first half of the 18th century. It was then, however, that a really remarkable man appeared, the archdeacon Salustio Antonio Bandini Bandini (1677-1760), author of the *Discorso sulla Marenmma Sicnese*, written in 1737, but not published till 1775. The object of the work was to raise the

Maremma from the wretched condition into which it had fallen through the decay of agriculture. This decay he showed to be, at least in part, the result of the wretched fiscal system which was in force; and his book led to important reforms in Tuscany, where his name is held in high honor. Not only by Pecchio and other Italian writers, but by Roscher also, he is alleged to have anticipated some leading doctrines of the physiocrats, but this claim is disputed. There was a remarkable renaissance of economic studies in Italy during the latter half of the century, partly due to French influence, and partly, it would appear, to improved government in the northern states.

The movement at first followed the lines of the mercantile school. Thus, in Antonio Broggia's *Trattati dei tributi e delle monete del governo politico della società* (1743), and Girolamo Belloni's *Dissertazione sopra il commercio* (1750), which seems to have had a success and reputation much above its merits, mercantilist tendencies decidedly preponderate. But the most distinguished writer who represented that economic doctrine in

Italy in the last century was Antonio Genovesi, a Neapolitan (1712-1769). He felt deeply the depressed intellectual and moral state of his fellow-countrymen, and aspired after a revival of philosophy and reform of education as the first condition of progress and well-being. With the object of protecting him from the theological persecutions which threatened him on account of his advanced opinions, Bartolomeo Intieri, of whom we shall hear again in relation to Galiani, founded in 1755, expressly for Genovesi, a chair of commerce and mechanics, one of the conditions of foundation being that it should never be filled by a monk. This was the first professorship of economics established in Europe; the second was founded at Stockholm in 1758, and the third in Lombardy ten years later, for Beccaria. The fruit of the labors of Genovesi in this chair was his *Lezioni di commercio, ossia di economia civile* (1769), which contained the first systematic treatment of the whole subject which had appeared in Italy. As the model for Italian imitation he held up England, a country for which, says Pecchio, he had a predilection almost amounting to fanaticism. He does not rise above the false economic system which England then pursued; but he rejects some of the grosser errors of the school to which he belonged; he advocates the freedom of the corn trade, and deprecates regulation of the interest on loans. In the spirit of his age, he denounces the relics of mediæval institutions, such as entails and

tenures in mortmain, as impediments to the national prosperity. Ferdinando Galiani was another distinguished disciple of the mercantile school. Before he had completed his twenty-first year he published a work on money (*Della moneta libri cinque*, 1750), the principles of which are supposed to have been dictated by two experienced practical men, the marquis Rinuccini and Bartolomeo Intieri, whose name we have already met. But his reputation was made by a book written in French and published in Paris, where he was secretary of embassy, in 1770, namely, his *Dialogues sur le commerce des blés*. This work, by its light and pleasing style, and the vivacious wit with which it abounded, delighted Voltaire, who spoke of it as a book in the production of which Plato and Molière might have been combined! The author, says Pecchio, treated his arid subject as Fontenelle did the vortices of Descartes, or Algarotti the Newtonian system of the world. The question at issue was that of the freedom of the corn trade, then much agitated, and, in particular, the policy of the royal edict of 1764, which permitted the exportation of grain so long as the price had not arrived at a certain height. The general principle he maintains is that the best system in regard to this trade is to have no system,—countries differently circumstanced requiring, according to him, different modes of treatment. This seems a lame and impotent conclusion from the side of science; yet doubtless the physiocrats, with whom his controversy lay, prescribed on this, as on other subjects, rules too rigid for the safe guidance of statesmen, and Galiani may have rendered a real service by protesting against their absolute solutions of practical problems. He fell, however, into some of the most serious errors of the mercantilists,—holding, as indeed did also Voltaire and even Verri, that one country cannot gain without another losing, and in his earlier treatise going so far as to defend the action of Governments in debasing the currency.

Amongst the Italian economists who were most under the influence of the modern spirit, and in closest harmony with the general movement which

was impelling the Western nations towards a new social order, Cesare Beccaria (1738-1794) holds a foremost place. He is best known by his celebrated treatise *Dei delitti e delle pene*, by which Voltaire said he had made himself a benefactor of all Europe, and which, we are told, has been translated into twenty-two languages. The empress Catherine having invited him to fix his residence at St. Petersburg, the Austrian Government of Lombardy, in order to keep him at home, established expressly for him a chair of political economy; and in his *Elementi di economia pubblica* (1769-1771; not published, however, till 1804) are embodied his teachings as professor. The work is unfinished; he had divided the whole subject under the heads of agriculture, manufactures, commerce, taxation, government; but he has treated adequately only the first two heads, and the last two not at all, having been called to take part in the councils of the state. He was in some degree under the influence of physiocratic ideas, and holds that agriculture is the only strictly productive form of industry, whilst manufacturers and artisans are a sterile class. He was strongly opposed to monopolies and privileges, and to corporations in arts and trades; in general he warmly advocated internal industrial freedom, though in regard to foreign commerce a protectionist. In the special case of the corn trade he was not, any more than Galiani, a partisan of absolute liberty. His exposition of economic principles is concise and sententious, and he often states correctly the most important considerations relating to his subject without adding the developments which would be desirable to assist comprehension and strengthen conviction. Thus on "production capital" (*capitali fondatori*), as distinct from "revenue capital," in its application to agriculture, he presents in a condensed form essentially the same explanations as Turgot about the same time gave; and on the division of labor and the circumstances which cause different rates of wages in different employments, he in substance comes near to Smith, but without the fulness of illustration which is so attractive a feature of the *Wealth of Nations*. Pietro Verri (1728-1797), an intimate and life-long friend of Beccaria, was for

Verri.

twenty-five years one of the principal directors of the administration of Lombardy, in which capacity he originated many economic and other reforms. In his *Riflessioni sulle leggi vincolanti, principalmente nel commercio d'grani* (written in 1769, printed in 1796), he considers the question of the regulation of the corn trade both historically and in the light of theoretic principles, and arrives at the conclusion that liberty is the best remedy against famine and against excessive fluctuations of price. He is generally opposed to Governmental interference with internal commerce, as well as to trade corporations, and the attempts to limit prices or fix the rate of interest, but is in favor of the protection of national industry by a judiciously framed tariff. These views are explained in his *Meditazioni sull'economia politica* (1771), an elementary treatise on the science, which was received with favor, and translated into several foreign languages. A primary principle with him is what he calls the augmentation of reproduction—that is, in Smith's language, of "the annual produce of the land and labor" of a nation; and by its tendency to promote or to restrict this augmentation he tests every enactment and institution. Accordingly, unlike Beccaria, he prefers the *petite* to the *grande culture*, as giving a larger total produce. In dealing with taxation, he rejects the physiocratic proposal of a single *impôt territorial*. Giovanni R. Carli (1720-1795), also an official promoter of the reforms in the government of Austrian

Carli.

Lombardy, beside learned and sound treatises on money, was author of *Ragionamenti sopra i bilanci economici delle nazioni*, in which he shows the falsity of the notion that a state gains or loses in foreign commerce according to the so-called balance of trade. In his letter to Pompeo Neri *Sull' libero commercio de' grani* (1771), he takes up a position similar to that of Galiani, regarding the question of the freedom of the corn trade as not so much a scientific as an administrative one, to be dealt with differently under different local or other conditions. Rejecting the physiocratic doctrine of the exclusive productiveness of agriculture, he illustrates in an interesting way the necessity of various economic classes in a society, and the reflex agency of manufactures in stimulating the cultivation of the soil. Giambattista Vasco (1733-1796), wrote discourses on several questions proposed by academies and sovereigns. In these he condemns trade corporations and the attempts by Governments to fix the price of bread and to limit the interest on loans. In advocating the system of a peasant proprietary, he suggests that the law should determine the minimum and maximum portions of land which a citizen should be permitted to possess. He also, with a view to prevent the undue accumulation of

Vasco.

property, proposes the abolition of the right of bequest, and the equal division of the inheritance amongst the children of the deceased. Gaetano Filangieri (1752-1788), one of the Italian writers of the last century whose names are most widely known throughout Europe, devoted to economic questions the second book of his *Scienza della legislazione* (5 vols., 1780-1785). Filled with reforming ardor and a passionate patriotism, he employed his vehement eloquence in denouncing all the abuses of his time. Apparently without any knowledge of Adam Smith, he insists on unlimited freedom of trade, calls for the abolition of the mediæval institutions which impeded production and national well-being, and condemns the colonial system then followed by England, Spain and Holland. He prophesies, as Raynal and Genovesi had done before him, that all America would one day be independent, a prediction which probably helped to elicit Benjamin Franklin's tribute of admiration for his work. Rather a propagator than a discoverer, he sometimes adopted from others erroneous opinions, as, for example, when he approves the *impôt unique* of the physiocrats. On the whole, however, he represents the most advanced political and social tendencies of his age; whilst strongly contrasted with Beccaria in temperament and style, he was a

worthy laborer in the same cause of national and universal progress. Ludovico Ricci (1742-1799) was author of an able report *Sulla riforma degli istituti pii della città di Modena* (1787). He treated the subject of poor relief and charitable institutions in so general a way that the work possesses a universal and permanent interest. He dwells on the evils of indiscriminate relief as tending to increase the misery it seeks to remove, and as lowering the moral character of a population. He exposes especially the abuses connected with lying-in and foundling hospitals. There is much in him which is akin to the views of Malthus; like him he is opposed to any state provision for the destitute, who ought, he thinks, to be left to voluntary private beneficence.

Paoletti. Ferdinando Paoletti (1717-1801) was an excellent and public-spirited priest, who did much for the diffusion of intelligence amongst the agricultural population of Tuscany, and for the lightening of the taxes which pressed upon them. He corresponded with Mirabeau ("Friend of Men"), and appears to have accepted the physiocratic doctrines, at least in their general substance. He was author of *Pensieri sopra l'agricoltura* (1769), and of *I veri mezzi di render felice le società* (1772); in the latter he advocates the freedom of the corn trade. The tract *Il Colbertismo* (1791) by Count Francesco Mengotti is a vigorous protest against the extreme policy of prohibition and protection, which may still be read with interest. Mengotti also wrote (1791) a treatise *Del commercio de' Romani*, directed mainly against the exaggerations of Huet in his *Histoire du commerce et de la navigation des anciens* (1716), and useful as marking the broad difference between the ancient and modern civilizations.

Here lastly may be mentioned another Italian thinker who, eminently original and even eccentric, cannot easily be classed among his contemporaries, though some Continental writers of our own century have exhibited similar modes of thought. This was Giammaria Ortes (1713-1790). He is opposed to the liberalist tendencies of his time, but does not espouse the doctrines of the mercantile system, rejecting the theory of the balance of trade and demanding commercial freedom. It is in the Middle Ages that he finds his social and economic type. He advocates the maintenance of church property, is averse to the ascendancy of the money power, and has the mediæval dislike for interest on loans. He entertains the singular idea that the wealth of communities is always and everywhere in a fixed ratio to their population, the latter being determined by the former. Poverty, therefore, necessarily waits on wealth, and the rich, in becoming so, only gain what the poor lose. Those who are interested in the improvement of the condition of the people labor in vain, so long as they direct their efforts to the increase of the sum of the national wealth, which it is beyond their power to alter, instead of to the distribution of that wealth, which it is possible to modify. The true remedy for poverty lies in mitigating the gain-pursuing propensities in the rich and in men of business. Ortes studied in a separate work the subject of population; he formulates its increase as "geometrical," but recognizes that, as a limit is set to such increase amongst the lower animals by mutual destruction, so is it in the human species by "reason"—the "prudential restraint" of which Malthus afterwards made so much. He regards the institution of celibacy as no less necessary and advantageous than that of marriage. He enunciates what has since been known as the "law of

diminishing returns to agricultural industry." He was careless as to the diffusion of his writings; and hence they remained almost unknown till they were included in the Custodi collection of Italian economists, when they attracted much attention by the combined sagacity and waywardness which marked their author's intellectual character.

Spain.—The same breath of a new era which was in the air elsewhere in Europe made itself felt also in Spain.

In the earlier part of the 18th century Geronimo Ustariz had written his *Teorica y Practica del Comercio y Marina* (1724; published, 1740; Eng. transl. by Ustariz. John Kippax, 1751; French by Forbounais, 1753), in which he carries mercantile principles to their utmost extreme.

The reforming spirit of the latter half of the century was best represented in that country by Pedro Rodríguez, Count of Campomanes (1723-1802). He pursued with ardor the same studies and in some degree the same policy as his illustrious contemporary Turgot, without, however, having arrived at so advanced a point of view. He was author of *Respuesta fiscal sobre abolir la tasa y establecer el comercio de granos* (1764), *Discurso sobre el fomento de industria popular* (1774), and *Discurso sobre la educacion de los artesanos y su fomento* (1775). By means of these writings, justly eulogized by Robertson, as well as by his personal efforts as minister, he sought to establish the freedom of the corn trade, to remove the hindrances to industry arising from mediæval survivals, to give a large development to manufactures, and to liberate agriculture from the odious burdens to which it was subject. He saw that, notwithstanding the enlightened administration of Charles III., Spain still suffered from the evil results of the blind confidence reposed by her people in her gold mines, and enforced the lesson that the real sources of the wealth and power of his country must be sought, not in America, but in her own industry.

In both Italy and Spain, as is well observed by Comte, the impulse towards social change took principally the direction of economic reform, because the pressure exercised by Governments prevented so large a measure of free speculation in the fields of philosophy and general politics as was possible in France. In Italy, it may be added, the traditions of the great industrial past of the northern cities of that country also tended to fix attention chiefly on the economic side of public policy and legislation.

Germany.—We have seen that in Italy and England political economy had its beginnings in the study of practical questions relating chiefly to money or to foreign commerce. In Germany it arose (as Roscher has shown) out of the so-called cameralistic sciences. From the end of the Middle Ages there existed in most German countries a council, known as the Kammer (Lat. *camera*), which was occupied with the management of the public domain and the guardianship of regal rights. The emperor Maximilian found this institution existing in Burgundy, and established, in imitation of it, aulic councils at Innsbruck and Vienna in 1498 and 1501. Not only finance and taxation, but questions also of economic police, came to be intrusted to these bodies. A special preparation became necessary for their members, and chairs of cameralistic science were founded in universities for the teaching of the appropriate body of doctrine. One side of the instruction thus given borrowed its materials from the sciences of external nature, dealing, as it did, with forestry, mining, general technology, and the like; the other related to the conditions of national prosperity as depending on human relations and institutions; and out of the latter German political economy was at first developed.

In no country had mercantilist views a stronger hold than in Germany, though in none, in the period we are now considering, did the system of the balance of trade receive a less extensive practical application. All the leading German economists of the 17th century—Bornitz, Besold, Klock, Becher, Horneck, Seckendorf, and Schröder—stand on the common basis of the mercantile doctrine. And the same may be said of the writers of the first half of the 18th

century in general, and notably of Justi (d. 1771), who was the author of the first systematic German treatise on political economy, a work which, from its currency as a text book, had much effect on the formation of opinion. Only in Zincke (1692-1769) do we find occasional expressions of a circle of ideas at variance with the dominant system, and pointing in the direction of industrial freedom.

But these writers, except from a national point of view, are unimportant, not having exercised any influence on the general movement of European thought.

The principles of the physiocratic system met with a certain amount of favor in Germany. Karl Friedrich, margrave of Baden, wrote for the use of his sons an *Abrégé des principes d'Economie Politique*, 1772, which is in harmony with the doctrines of that system. It possesses, however, little scientific value. Schlettwein (1731-1802) and Mauvillon (1743-1794) were followers of the same school. Theodor Schmalz (1764-1831), who is commonly named as "the last of the physiocrats," may be here mentioned, though somewhat out of the historic order. He compares Colbertism with the Ptolemaic system, physiocracy with the Copernican. Adam Smith he represents as the Tycho Brahe of political economy,—a man of eminent powers, who could not resist the force of truth in the physiocrats, but partly could not divest himself of rooted prejudices, and partly was ambitious of the fame of a discoverer and a reconciler of divergent systems. Though Smith was now "the fashion," Schmalz could not doubt that Quesnay's doctrine was alone true, and would ere long be triumphant everywhere.

Just before the appearance of Smith, as in England Stuart, and in Italy Genovesi, so in Austria Sonnenfels. Sonnenfels (1733-1817), the first distinguished economist of that country, sought to present the mercantile system in a modified and more enlightened form; and his work (*Grundsätze der Polizei, Handlung, und Finanz*, 1765; 8th ed., 1822) exercised even during a considerable part of the present century much influence on opinion and on policy in Austria.

But the greatest German economist of the 18th century was, in Roscher's opinion, Justus Möser (1720-1794, the author of *Patriotische Phantasieen* 1774), a series of fragments, which, Goethe nevertheless declares, form, "ein wahrhaftes Ganzes." The poet was much influenced by Möser in his youth, and has eulogized in the *Dichtung und Wahrheit* his spirit, intellect, and character, and his thorough insight into all that goes on in the social world. Whilst others occupied themselves with larger and more prominent public affairs and transactions, Möser observed and reproduced the common daily life of his nation, and the thousand "little things" which compose the texture of popular existence. He has been compared to Franklin for the homeliness, verve, and freshness of his writings. In opinions he is akin to the Italian Ortes. He is opposed to the whole spirit of the "Aufklärung," and to the liberal and rationalistic direction of which Smith's work became afterwards the expression. He is not merely conservative but reactionary, manifesting a preference for mediæval institutions such as the trade guilds, and, like Carlyle in our own time, seeing advantages even in serfdom, when compared with the sort of freedom enjoyed by the modern drudge. He has a marked antipathy for the growth of the money power and of manufactures on the large scale, and for the highly developed division of labor. He is opposed to absolute private property in land, and would gladly see revived such a system of restrictions as in the interest of the state, the commune, and the family were imposed on mediæval ownership. In his wayward and caustic style, he often criticizes effectively the doctrinaire narrowness of his contemporaries, throws out many striking ideas, and in particular sheds real light on the economic phenomena and general social conditions of the Middle Ages.

2. Adam Smith, with his Immediate Predecessors and his Followers.

England.—The stagnation in economic inquiry which showed itself in England in the early part of the 18th century was not broken by any notable manifestation before 1735, when Bishop Berkeley put forward in his *Querist*, with much force and point, views opposed to those of the mercantile school on the nature of national wealth and the functions of money, though not without an admixture of grave error. But soon a more decisive advance was made. Whilst in

France the physiocrats were working after their own fashion towards the construction of a definitive system of political economy, a Scottish thinker of the first order was elucidating, in a series of short but pregnant essays, some of the fundamental conceptions of the science. What had been written on these questions in the English language before his time had remained almost altogether within the limits of the directly practical sphere. With Locke, indeed, the general system of the modern critical philosophy had come into relation with economic inquiry, but only in a partial and indeterminate way. But in Hume the most advanced form of this philosophy was represented, and his appearance in the field of economics decisively marks the tendency of the latter order of speculation to place itself in connection with the largest and deepest thought on human nature and general human history. Most of the essays here referred to first appeared in 1752, in a volume entitled *Political Discourses*, and the number was completed in the collection of *Essays and Treatises on Several Subjects*, published in the following year. The most important of them are those on Commerce, on Money, on Interest, and on the Balance of Trade. Yet these should not be separated from the rest, for, notwithstanding the unconnected form of these little treatises, there runs through them a profound unity of thought, so that they indeed compose in a certain sense an economic system. They exhibit in full measure Hume's wonderful acuteness and subtlety, which indeed sometimes dispose him to paradox, in combination with the breadth, the absence of prejudice, and the social sympathies which so eminently distinguish him; and they offer, besides, the charm of his easy and natural style and his rare power of lucid exposition.

In the essay on money he refutes the mercantilist error, which tended to confound it with wealth. "Men and commodities," he says, "are the real strength of any community." "In the national stock of labor consists all real power and riches." Money is only the oil which makes the movements of the mechanism of commerce more smooth and easy. He shows that, from the domestic as distinguished from the international point of view, the absolute quantity of money, supposed as of fixed amount, in a country is of no consequence, whilst an excessive quantity, larger, that is, than is required for the interchange of commodities, may be injurious as raising prices and driving foreigners from the home markets. He goes so far, in one or two places, as to assert that the value of money is chiefly fictitious or conventional, a position which cannot be defended; but it must not be pressed against him, as he builds nothing on it. He has some very ingenious observations (since, however, questioned by J. S. Mill) on the effects of the increase of money in a country in stimulating industry during the interval which takes place before the additional amount is sufficiently diffused to alter the whole scale of prices. He shows that the fear of the money of an industrious community being lost to it by passing into foreign countries is groundless, and that, under a system of freedom, the distribution of the precious metals which is adapted to the requirements of trade will spontaneously establish itself. "In short, a Government has great reason to preserve with care its people and its manufactures; its money it may safely trust to the course of human affairs without fear or jealousy."

A very important service was rendered by his treatment of the rate of interest. He exposes the erroneous idea often entertained that it depends on the quantity of money in a country, and shows that the reduction of it must in general be the result of "the increase of industry and frugality, of arts and commerce," so that it may serve as a barometer, its lowness being an almost infallible sign of the flourishing condition of a people. It may be observed in passing that in the essay devoted to this subject he brings out a principle of human nature which economists too often overlook, "the constant and insatiable desire of the mind for exercise and employment," and the consequent action of *ennui* in prompting to exertion.

With respect to commerce, he points to its natural foundation in what has since been called "the territorial division of labor," and proves that the prosperity of one nation, instead of being a hindrance, is a help to that of its neighbors. "Not only as a man, but as a British subject," he says, "I pray for the flourishing commerce of Germany,

Spain, Italy, and even France itself." He condemns the "numberless bars, obstructions, and imposts which all nations of Europe, and none more than England, have put upon trade." Yet on the question of protection to national industry he is not quite at the free-trade point of view, for he approves of a tax on German linen as encouraging home manufactures, and of a tax on brandy as increasing the sale of rum and supporting our southern colonies. Indeed it has been justly observed that there are in him several traces of a refined mercantilism, and that he represents a state of opinion in which the transition from the old to the new views is not yet completely effected.

We cannot do more than refer to the essay on taxes, in which, amongst other things, he repudiates the *impôt unique* of the physiocrats, and to that on public credit, in which he criticises the "new paradox that public incumbrances are of themselves advantageous, independent of the necessity of contracting them," and objects, perhaps too absolutely, to the modern expedient of raising the money required for national enterprises by way of loan, and so shifting our burdens upon the shoulders of posterity.

The characteristics of Hume which are most important in the history of economic investigation are (1) his practice of bringing economic facts into connection with all the weighty interests of social and political life, and (2) his tendency to introduce the historical spirit into the study of those facts. He admirably illustrates the mutual action of the several branches of industry, and the influences of progress in the arts of production and in commerce on general civilization, exhibits the striking contrasts of the ancient and modern system of life (see especially the essay *On the Populousness of Ancient Nations*), and considers almost every phenomenon which comes under discussion in its relations to the contemporary stage of social development. It cannot be doubted that Hume exercised a most important influence on Adam Smith, who in the *Wealth of Nations* calls him "by far the most illustrious philosopher and historian of the present age," and who esteemed his character so highly that, after a friendship of many years had been terminated by Hume's decease, he declared him to have "approached as nearly to the idea of a perfectly wise and virtuous man as perhaps the nature of human frailty will permit."

Josiah Tucker, dean of Gloucester (d. 1799), holds a distinguished place among the immediate predecessors of Smith. Most of his numerous productions had direct reference to contemporary questions, and, though marked by much sagacity and penetration are deficient in permanent interest. In some of these he urged the impolicy of restrictions on the trade of Ireland, advocated a union of that country with England, and recommended the recognition of the independence of the United States of America. The most important of his general economic views are those relating to international commerce. He is an ardent supporter of free-trade doctrines, which he bases on the principle that there is between nations no necessary antagonism, but rather a harmony, of interests, and that their several natural advantages and different aptitudes naturally prompt them to exchange. He had not, however, got quite clear of mercantilism, and favored bounties on exported manufactures and the encouragement of population by a tax on celibacy. Dupont, and after him Blanqui, represent Tucker as a follower of the physiocrats, but there seems to be no ground for this opinion except his agreement with them on the subject of the freedom of trade. Turgot translated into French his *Important Questions on Commerce* (1755).

In 1767 was published Sir James Steuart's *Inquiry into the Principles of Political Economy*. This was one of the most unfortunate of books. It was the most complete and systematic survey of the science from the point of view of moderate mercantilism which had appeared in England. Steuart was a man of no ordinary abilities, and had prepared himself for his task by long and serious study. But the time for the mercantile doctrines was past, and the system of natural liberty was in possession of an intellectual ascendancy which foreshadowed its political triumph. Nine years later the *Wealth of Nations* was given to the world, a work as superior to Steuart's in attractiveness of style as in scientific soundness. Thus the latter was predestined to fail, and in fact never exercised any considerable theoretic or practical influence. Smith never quotes or mentions it; being acquainted with Steuart, whose conver-

sation he said was better than his book, he probably wished to keep clear of controversy with him. The German economists have examined Steuart's treatise more carefully than English writers have commonly done; and they recognize its high merits, especially in relation to the theory of value and the subject of population. They have also pointed out that, in the spirit of the best recent research, he has dwelt on the special characters which distinguish the economies proper to different nations and different grades in social progress.

Coming now to the great name of Adam Smith (1723-1790), it is of the highest importance that we should rightly understand his position and justly estimate his claims. It is plainly contrary to fact to represent him, as some have done, as the creator of political economy. The subject of social wealth had always in some degree, and increasingly in recent times, engaged the attention of philosophic minds. The study had even indisputably assumed a systematic character, and, from being an assemblage of fragmentary disquisitions on particular questions of national interest, had taken the form, notably in Turgot's *Réflexions*, of an organized body of doctrine. The truth is that Smith took up the science when it was already considerably advanced; and it was this very circumstance which enabled him, by the production of a classical treatise, to render most of his predecessors obsolete. But, whilst all the economic labors of the preceding centuries prepared the way for him, they did not anticipate his work. His appearance at an earlier stage, or without those previous labors, would be inconceivable; but he built on the foundation which had been laid by others much of his own that was precious and enduring.

Even those who do not fall into the error of making Smith the creator of the science, often separate him too broadly from Quesnay and his followers, and represent the history of modern economics as consisting of the successive rise and reign of three doctrines—the mercantile, the physiocratic, and the Smithian. The last two are, it is true, at variance in some even important respects. But it is evident, and Smith himself felt, that their agreements were much more fundamental than their differences; and, if we regard them as historical forces, they must be considered as working towards identical ends. They both urged society towards the abolition of the previously prevailing industrial policy of European Governments; and their arguments against that policy rested essentially on the same grounds. Whilst Smith's criticism was more searching and complete, he also analyzed more correctly than the physiocrats some classes of economic phenomena,—in particular dispelling the illusions into which they had fallen with respect to the unproductive nature of manufactures and commerce. Their school disappeared from the scientific field, not merely because it met with a political check in the person of Turgot, but because, as we have already said, the *Wealth of Nations* absorbed into itself all that was valuable in their teaching, whilst it continued more effectually the impulse they had given to the necessary work of demolition.

The history of economic opinion in modern times, down to the third decade of our own century, is, in fact, strictly bipartite. The first stage is filled with the mercantile system, which, as we have shown, was rather a practical policy than a speculative doctrine, and which came into existence as the spontaneous growth of social conditions acting on minds not trained to scientific habits. The second stage is occupied with the gradual rise and ultimate ascendancy of another system founded on the idea of the right of the individual to an unimpeded sphere for the exercise of his economic activity. With the latter, which is best designated as the "system of natural liberty," we ought to associate the memory of the physiocrats as well as that of Smith, without, however, maintaining their services to have been equal to his.

The teaching of political economy was in the Scottish

Adam
Smith.

universities associated with that of moral philosophy. Smith, as we are told, conceived the entire subject he had to treat in his public lectures as divisible into four heads, the first of which was natural theology, the second ethics, the third jurisprudence; whilst in the fourth "he examined those political regulations which are founded upon expediency, and which are calculated to increase the riches, the power, and the prosperity of a state." The last two branches of inquiry are regarded as forming but a single body of doctrine in the well-known passage of the *Theory of Moral Sentiments* in which the author promises to give in another discourse "an account of the general principles of law and government, and of the different revolutions they have undergone in the different ages and periods of society, not only in what concerns justice, but in what concerns police, revenue, and arms, and whatever else is the subject of law." This shows how little it was Smith's habit to separate (except provisionally), in his conceptions or his researches, the economic phenomena of society from all the rest. The words above quoted have, indeed, been not unjustly described as containing "an anticipation, wonderful for his period, of general sociology, both statical and dynamical, an anticipation which becomes still more remarkable when we learn from his literary executors that he had formed the plan of a connected history of the liberal sciences and elegant arts, which must have added to the branches of social study already enumerated a view of the intellectual progress of society." Though these large designs were never carried out in their integrity, as indeed at that period they could not have been adequately realized, it has resulted from them that, though economic phenomena form the special subject of the *Wealth of Nations*, Smith yet incorporated into that work much that relates to the other social aspects, incurring thereby the censure of some of his followers, who insist with pedantic narrowness on the strict isolation of the economic domain.

There has been much discussion on the question—What is the scientific method followed by Smith in his great work? By some it is considered to have been purely deductive, a view which Buckle has perhaps carried to the greatest extreme. He asserts that in Scotland the inductive method was unknown, that the inductive philosophy exercised no influence on Scottish thinkers; and, though Smith spent some of the most important years of his youth in England, where the inductive method was supreme, and though he was widely read in general philosophical literature, he yet thinks he adopted the deductive method because it was habitually followed in Scotland,—and this though Buckle maintains that it is the only appropriate, or even possible, method in political economy, which surely would have been a sufficient reason for choosing it. That the inductive spirit exercised no influence on Scottish philosophers is certainly not true; as will be presently shown, Montesquieu, whose method is essentially inductive, was in Smith's time studied with quite peculiar care and regarded with special veneration by Smith's fellow-countrymen. As to Smith himself, what may justly be said of him is that the deductive bent was certainly not the predominant character of his mind, nor did his great excellence lie in the "dialectic skill" which Buckle ascribes to him. What strikes us most in his book is his wide and keen observation of social facts, and his perpetual tendency to dwell on these and elicit their significance, instead of drawing conclusions from abstract principles by elaborate chains of reasoning. It is this habit of his mind which gives us, in reading him, so strong and abiding a sense of being in contact with the realities of life.

That Smith does, however, largely employ the deductive method is certain; and that method is quite legitimate when the premises from which the deduction sets out are known universal facts of human nature and properties of external objects. Whether this

mode of proceeding will carry us far may indeed well be doubted; but its soundness cannot be disputed. But there is another vicious species of deduction which, as Cliffe Leslie has shown, seriously tainted the philosophy of Smith,—in which the premises are not facts ascertained by observation, but the same *a priori* assumptions, half theological half metaphysical, respecting a supposed harmonious and beneficent natural order of things which we found in the physiocrats, and which, as we saw, were embodied in the name of that sect. In his view Nature has made provision for social well-being by the principle of the human constitution which prompts every man to better his condition: the individual aims only at his private gain, but in doing so is "led by an invisible hand" to promote the public good, which was no part of his intention; human institutions, by interfering with the action of this principle in the name of the public interest, defeat their own end; but when all systems of preference or restraint are taken away, "the obvious and simple system of natural liberty establishes itself of its own accord." This theory is, of course, not explicitly presented by Smith as a foundation of his economic doctrines, but it is really the secret substratum on which they rest. Yet, whilst such latent postulates warped his view of things, they did not entirely determine his method. His native bent towards the study of things as they are preserved him from extravagances into which many of his followers have fallen. But besides this, as Leslie has pointed out, the influence of Montesquieu tended to counterbalance the theoretic prepossessions produced by the doctrine of the *ius naturalæ*. That great thinker, though he could not, at his period, understand the historical method which is truly appropriate to sociological inquiry, yet founded his conclusions on induction. It is true, as Comte has remarked, that his accumulation of facts, borrowed from the most different states of civilization, and not subjected to philosophic criticism, necessarily remained on the whole sterile, or at least could not essentially advance the study of society much beyond the point at which he found it. His merit, as we have before mentioned, lay in the recognition of the subjection of all social phenomena to natural laws, not in the discovery of those laws. But this limitation was overlooked by the philosophers of the time of Smith, who were much attracted by the system he followed of tracing social facts to the special circumstances, physical or moral, of the communities in which they were observed. Leslie has shown that Lord Kaimes, Dalmory, and Millar—contemporaries of Smith, and the last his pupil—were influenced by Montesquieu; and he might have added the more eminent name of Ferguson, whose respect and admiration for the great Frenchman are expressed in striking terms in his *History of Civil Society*. We are even informed that Smith himself in his later years was occupied in preparing a commentary on the *Esprit des Lois*. He was thus affected by two different and incongruous systems of thought,—one setting out from an imaginary code of nature intended for the benefit of man, and leading to an optimistic view of the economic constitution founded on enlightened self-interest; the other following inductive processes, and seeking to explain the several states in which human societies are found existing, as results of circumstances or institutions which have been in actual operation. And we find accordingly in his great work a combination of these two modes of treatment—inductive inquiry on the one hand, and, on the other, *a priori* speculation founded on the "Nature" hypothesis. The latter vicious proceeding has in some of his followers been greatly aggravated, while the countervailing spirit of inductive investigation has fallen into the background, and indeed the necessity or utility of any such investigation in the economic field has been sometimes altogether denied.

Some have represented Smith's work as of so loose a texture and so defective in arrangement that it may

be justly described as consisting of a series of monographs. But this is certainly an exaggeration. The book, it is true, is not framed on a rigid mould, nor is there any parade of systematic divisions and subdivisions; and this doubtless recommended it to men of the world and of business, for whose instruction it was, at least primarily, intended. But, as a body of exposition, it has the real and pervading unity which results from a mode of thinking homogeneous throughout and the general absence of such contradictions as would arise from an imperfect digestion of the subject.

Smith sets out from the thought that the annual labor of a nation is the source from which it derives its supply of the necessities and conveniences of life. He does not of course contemplate labor as the only factor in production; but it has been supposed that by emphasizing it at the outset he at once strikes the note of difference between himself on the one hand and both the mercantilists and the physiocrats on the other. The improvement in the productiveness of labor depends largely on its division; and he proceeds accordingly to give his unrivalled exposition of that principle, of the grounds on which it rests, and of its greater applicability to manufactures than to agriculture, in consequence of which the latter relatively lags behind in the course of economic development. The origin of the division of labor he finds in the propensity of human nature "to truck, barter, or exchange one thing for another." He shows that a certain accumulation of capital is a condition precedent of this division, and that the degree to which it can be carried is dependent on the extent of the market. When the division of labor has been established, each member of the society must have recourse to the others for the supply of most of his wants; a medium of exchange is thus found to be necessary, and money comes into use. The exchange of goods against each other or against money gives rise to the notion of value. This word has two meanings—that of utility, and that of purchasing power; the one may be called value in use, the other value in exchange. Merely mentioning the former, Smith goes on to study the latter. What, he asks, is the measure of value? what regulates the amount of one thing which will be given for another? "Labor," Smith answers, "is the real measure of the exchangeable value of all commodities." "Equal quantities of labor, at all times and places, are of equal value to the laborer." "Labor alone, therefore, never varying in its own value, is alone the ultimate and real standard by which the value of all commodities can at all times and places be estimated and compared. It is their real price; money is their nominal price only." Money, however, is in men's actual transactions the measure of value, as well as the vehicle of exchange; and the precious metals are best suited for this function, as varying little in their own value for periods of moderate length; for distant times, corn is a better standard of comparison. In relation to the earliest social stage, we need consider nothing but the amount of labor employed in the production of an article as determining its exchange value; but in more advanced periods price is complex, and consists in the most general case of three elements—wages, profit, and rent. Wages are the reward of labor. Profit arises as soon as stock, being accumulated in the hands of one person, is employed by him in setting others to work, and supplying them with materials and subsistence, in order to make a gain by what they produce. Rent arises as soon as the land of a country has all become private property; "the landlords, like all other men, love to reap where they never sowed, and demand a rent even for its natural produce." In every improved society, then, these three elements enter more or less into the price of the far greater part of commodities. There is in every society or neighborhood an ordinary or average rate of wages and profit in every different employment of labor and stock regulated by principles to be explained hereafter, as also an ordinary or average rate of rent. These may be called the natural rates at the time when and the place where they prevail; and the natural price of a commodity is what is sufficient to pay for the rent of the land, the wages of the labor, and the profit of the stock necessary for bringing the commodity to market. The market price may rise above or fall below the amount so fixed, being determined by the proportion between the quantity brought to market and the demand of those who are willing to pay the natural price. Towards the natural price as a centre the market-price, regulated by competition, constantly gravitates. Some commodities, however, are subject to a monopoly of production, whether from the peculiarities of a locality or from legal privilege: their price is always the highest that can be got; the natural price of

other commodities is the lowest which can be taken for any length of time together. The three component parts or factors of price vary with the circumstances of the society. The rate of wages is determined by a "dispute" or struggle of opposite interests between the employer and the workman. A minimum rate is fixed by the condition that they must be at least sufficient to enable a man and his wife to maintain themselves and, in general, bring up a family. The excess above this will depend on the circumstances of the country, and the consequent demand for labor,—wages being high when national wealth is increasing, low when it is declining. The same circumstances determine the variation of profits, but in an opposite direction; the increase of stock, which raises wages, tending to lower profit through the mutual competition of capitalists. "The whole of the advantages and disadvantages of the different employments of labor and stock must, in the same neighborhood, be either perfectly equal or continually tending to equality;" if one had greatly the advantage over the others, people would crowd into it, and the level would soon be restored. Yet pecuniary wages and profits are very different in different employments,—either from certain circumstances affecting the employments, which recommend or disparage them in men's notions, or from national policy, "which nowhere leaves things at perfect liberty." Here follows Smith's admirable exposition of the causes which produce the inequalities in wages and profits just referred to, a passage affording ample evidence of his habits of nice observation of the less obvious traits in human nature, and also of the operation both of these and of social institutions on economic facts. The rent of land comes next to be considered, as the last of the three elements of price. Rent is a monopoly price, equal, not to what the landlord could afford to take, but to what the farmer can afford to give. "Such parts only of the produce of land can commonly be brought to market, of which the ordinary price is sufficient to replace the stock which must be employed in bringing them thither, together with the ordinary profits. If the ordinary price is more than this, the surplus part will naturally go to the rent of the land. If it is not more, though the commodity may be brought to market, it can afford no rent to the landlord. Whether the price is or is not more depends on the demand." "Rent, therefore, enters into the price of commodities in a different way from wages and profits. High or low wages and profit are the causes of high or low price; high or low rent is the effect of it."

Rent, wages, and profits, as they are the elements of price, are also the constituents of income; and the three great orders of every civilized society, from whose revenues that of every order is ultimately derived, are the landlords, the laborers, and the capitalists. The relation of the interests of these three classes to those of society at large is different. The interest of the landlord always coincides with the general interest; whatever promotes or obstructs the one has the same effect on the other. So also does that of the laborer: when the wealth of the nation is progressive, his wages are high; they are low when it is stationary or retrogressive. "The interest of the third order has not the same connection with the general interest of the society as that of the other two; . . . it is always in some respects different from and opposite to that of the public."

The subject of the second book is "the nature, accumulation, and improvement of stock." A man's whole stock consists of two portions—that which is reserved for his immediate consumption, and that which is employed so as to yield a revenue to its owner. This latter, which is his "capital," is divisible into the two classes of "fixed" and "circulating." The first is such as yields a profit without passing into other hands. The second consists of such goods, raised, manufactured, or purchased, as are sold for a profit and replaced by other goods; this sort of capital is therefore constantly going from and returning to the hands of its owner. The whole capital of a society falls under the same two heads. Its fixed capital consists chiefly of (1) machines, (2) buildings which are the means of procuring a revenue, (3) agricultural improvements, and (4) the acquired and useful abilities of all members of the society (since sometimes known as "personal capital"). Its circulating capital is also composed of four parts—(1) money, (2) provisions in the hands of the dealers, (3) materials, and (4) completed work in the hands of the manufacturer or merchant. Next comes the distinction of the gross national revenue from the net,—the first being the whole produce of the land and labor of a country, the second what remains after deducting the expense of maintaining the fixed capital of the country and that part of its circulating capital which consists of money. Money, "the great wheel of circulation," is altogether different from the goods which are circulated by means of it; it is a costly instrument by means of which all that each individual receives is distributed to him; and

the expenditure required, first to provide it, and afterwards to maintain it, is a deduction from the net revenue of the society. In development of this consideration, Smith goes on to explain the gain to the community arising from the substitution of paper money for that composed of the precious metals; and here occurs the remarkable illustration in which the use of gold and silver money is compared to a highway on the ground, that of paper money to a wagon way through the air. In proceeding to consider the accumulation of capital, he is led to the distinction between productive and unproductive labor,—the former being that which is fixed or realized in a particular object or vendible article, the latter that which is not so realized. The former is exemplified in the labor of the manufacturing workman, the latter in that of the menial servant. A broad line of demarcation is thus drawn between the labor which results in commodities or increased value of commodities, and that which does no more than render services: the former is productive, the latter unproductive. "Productive" is by no means equivalent to "useful": the labors of the magistrate, the soldier, the churchman, lawyer, and physician, are, in Smith's sense, unproductive. Productive laborers are alone employed out of capital; unproductive laborers, as well as those who do not labor at all, are all maintained by revenue. In advancing industrial communities, the portion of annual produce set apart as capital, bears an increasing proportion to that which is immediately destined to constitute a revenue, either as rent or as profit. Parsimony is the source of the increase of capital; by augmenting the fund devoted to the maintenance of productive hands, it puts in motion an additional quantity of industry, which adds to the value of the annual produce. What is annually saved is as regularly consumed as what is spent, but by a different set of persons, by productive laborers instead of idlers or unproductive laborers; and the former reproduce with a profit the value of their consumption. The prodigal, encroaching on his capital, diminishes, as far as in him lies, the amount of productive labor, and so the wealth of the country; nor is this result affected by his expenditure being on home-made, as distinct from foreign, commodities. Every prodigal, therefore, is a public enemy; every frugal man a public benefactor. The only mode of increasing the annual produce of the land and labor is to increase either the number of productive laborers or the productive powers of those laborers. Either process will in general require additional capital, the former to maintain the new laborers, the latter to provide improved machinery to enable the employer to introduce a more complete division of labor. In what are commonly called loans of money, it is not really the money, but the money's worth, that the borrower wants; and the lender really assigns to him the right to a certain portion of the annual produce of the land and labor of the country. As the general capital of a country increases, so also does the particular portion of it from which the possessors wish to derive a revenue without being at the trouble of employing it themselves; and, as the quantity of stock thus available for loans is augmented, the interest diminishes, not merely "from the general causes which make the market price of things commonly diminish as their quantity increases," but because with the increase of capital, "it becomes gradually more and more difficult to find within the country a profitable method of employing any new capital,"—whence arises a competition between different capitals, and a lowering of profits, which must diminish the price which can be paid for the use of capital, or in other words the rate of interest. It was formerly wrongly supposed, and even Locke and Montesquieu did not escape this error, that the fall in the value of the precious metals consequent on the discovery of the American mines was the real cause of the general lowering of the rate of interest in Europe. But this view, already refuted by Hume, is easily seen to be erroneous. "In some countries the interest of money has been prohibited by law. But, as something can everywhere be made by the use of money, something ought everywhere to be paid for the use of it," and will in fact be paid for it; and the prohibition will only heighten the evil of usury by increasing the risk to the lender. The legal rate should be a very little above the lowest market rate; sober people will then be preferred as borrowers to prodigals and projectors, who at a higher legal rate would have an advantage over them, being alone willing to offer that higher rate.

As to the different employments of capital, the quantity of productive labor put in motion by an equal amount varies extremely according as that amount is employed—(1) in the improvement of lands, mines, or fisheries, (2) in manufactures, (3) in wholesale or (4) retail trade. In agriculture "Nature labors along with man," and not only the capital of the farmer is reproduced with his profits, but also the rent of the landlord. It is therefore the employment of a

given capital which is most advantageous to society. Next in order come manufacturers; then wholesale trade—first the home trade, secondly the foreign trade of consumption, last the carrying trade. All these employments of capital, however, are not only advantageous, but necessary, and will introduce themselves in the due degree, if they are left to the spontaneous action of individual enterprise.

These first two books contain Smith's general economic scheme; and we have stated it as fully as was consistent with the brevity here necessary, because from this formulation of doctrine the English classical school set out, and round it the discussions of more recent times in different countries have in a great measure revolved. Some of the criticisms of his successors and their modifications of his doctrines will come under our notice as we proceed.

The critical philosophers of the 18th century were often destitute of the historical spirit, which was no part of the endowment needed for their principal social office. But some of the most eminent of them, especially in Scotland, showed a marked capacity and predilection for historical studies. Smith was amongst the latter; Knies and others justly remark on the masterly sketches of this kind which occur in the *Wealth of Nations*. The longest and most elaborate of these occupies the third book; it is an account of the course followed by the nations of modern Europe in the successive development of the several forms of industry. It affords a curious example of the effect of doctrinal prepossessions in obscuring the results of historical inquiry. Whilst he correctly describes the European movement of industry, and explains it as arising out of adequate social causes, he yet, in accordance with the absolute principles which tainted his philosophy, protests against it as involving an entire inversion of the "natural order of things." First agriculture, then manufactures, lastly foreign commerce; any other order than this he considers "unnatural and retrograde." Hume, a more purely positive thinker, simply sees the facts, accepts them, and classes them under a general law. "It is a violent method," he says, "and in most cases impracticable, to oblige the laborer to toil in order to raise from the land more than what subsists himself and family. Furnish him with manufactures and commodities, and he will do it of himself." "If we consult history, we shall find that, in most nations, foreign trade has preceded any refinement in home manufactures, and given birth to domestic luxury."

The fourth book is principally devoted to the elaborate and exhaustive polemic against the mercantile system which finally drove it from the field of science, and has exercised a powerful influence on economic legislation. When protection is now advocated, it is commonly on different grounds from those which were in current use before the time of Smith. He believed that to look for the restoration of freedom of foreign trade in Great Britain would have been "as absurd as to expect that an Oceana or Utopia should be established in it;" yet, mainly in consequence of his labors, that object has been completely attained; and it has lately been said with justice that free trade might have been more generally accepted by other nations if the patient reasoning of Smith had not been replaced by dogmatism. His teaching on the subject is not altogether unqualified; but, on the whole, with respect to exchanges of every kind, where economic motives alone enter, his voice is in favor of freedom. He has regard, however, to political as well as economic interests, and on the ground that "defence is of much more importance than opulence," pronounces the Navigation Act to have been "perhaps the wisest of all the commercial regulations of England." Whilst objecting to the prevention of the export of wool, he proposes a tax on that export as somewhat less injurious to the interest of growers than the prohibition, whilst it would "afford a sufficient advantage" to the domestic over the foreign manufacturer. This is, perhaps, his most marked

deviation from the rigor of principle; it was doubtless a concession to popular opinion with a view to an attainable practical improvement. The wisdom of retaliation in order to procure the repeal of high duties or prohibitions imposed by foreign Governments depends, he says, altogether on the likelihood of its success in effecting the object aimed at, but he does not conceal his contempt for the practice of such expedients. The restoration of freedom in any manufacture, when it has grown to considerable dimensions by means of high duties, should, he thinks, from motives of humanity, be brought about only by degrees and with circumspection,—though the amount of evil which would be caused by the immediate abolition of the duties is, in his opinion, commonly exaggerated. The case in which J. S. Mill justified protection—that, namely, in which an industry well-adapted to a country is kept down by the acquired ascendancy of foreign producers—is referred to by Smith; but he is opposed to the admission of this exception for reasons which do not appear to be conclusive. He is perhaps scarcely consistent in approving the concession of temporary monopolies to joint-stock companies undertaking risky enterprises “of which the public is afterwards to reap the benefit.”¹

He is less absolute in his doctrine of Governmental non-interference when he comes to consider in his fifth book the “expenses of the sovereign or the commonwealth.” He recognizes as coming within the functions of the state the erection and maintenance of those public institutions and public works which, though advantageous to the society, could not repay, and therefore must not be thrown upon individuals or small groups of individuals. He remarks in a just historical spirit that the performance of these functions requires very different degrees of expense in the different periods of society. Besides the institutions and works intended for public defence and the administration of justice, and those required for facilitating the commerce of the society, he considers those necessary for promoting the instruction of the people. He thinks the public at large may with propriety not only facilitate and encourage, but even impose upon almost the whole body of the people, the acquisition in youth of the most essential elements of education. He suggests as the mode of enforcing this obligation the requirement of submission to a test examination “before any one could obtain the freedom in any corporation, or be allowed to set up a trade in any village or town corporate.” Similarly, he is of opinion that some probation, even in the higher and more difficult sciences, might be enforced as a condition of exercising any liberal profession, or becoming a candidate for any honorable office. The expense of the institutions for religious instruction as well as for general education, he holds, may without injustice be defrayed out of the funds of the whole society, though he would apparently prefer that it should be met by the voluntary contributions of those who think they have occasion for such education or instruction. There is much that is sound, as well as interesting and suggestive, in this fifth book, in which he shows a political instinct and a breadth of view by which he is favorably contrasted with the Manchester school. But, if we may say so without disrespect to so great a man, there are traces in it of what is now called Philistinism—a low view of the ends of art and poetry—which arose perhaps in part from personal defect, though it was common enough in even the higher minds in his century. There are also indications of a certain deadness to the lofty aims and perennial importance of religion, which was no doubt chiefly due to the influences of an age when the critical spirit was doing an indispensable work, in the performance of which the

transitory was apt to be confounded with the permanent.

For the sake of considering as a whole Smith's view of the functions of government, we have postponed noticing his treatment of the physiocratic system, which occupies a part of his fourth book. He had formed the acquaintance of Quesnay, Turgot, and other members of their group during his sojourn in France in 1765, and would, as he told Dugald Stewart, had the patriarch of the school lived long enough, have dedicated to him the *Wealth of Nations*. He declares that, with all its imperfections, the system of Quesnay is “perhaps the nearest approximation to the truth that had yet appeared on the subject of political economy.” Yet he seems not to be adequately conscious of the degree of coincidence between his own doctrines and those of the physiocrats. Dupont de Nemours complained that he did not do Quesnay the justice of recognizing him as his spiritual father. It is, however, alleged on the other side, that already in 1753 Smith had been teaching as professor a body of economic doctrine the same in its broad features with that contained in his great work. This is indeed said by Stewart; and, though he gives no evidence of it, it is possibly quite true; if so, Smith's doctrinal descent must be traced rather from Hume than from the French school. The principal error of this school, that, namely, of representing agricultural labor as alone productive, he refutes in the fourth book, though in a manner which has not always been considered effective. Traces of the influence of their mistaken view appear to remain in his own work, as, for example, his assertion that in agriculture nature labors along with man, whilst in manufactures nature does nothing, man does all; and his distinction between productive and unproductive labor, which was doubtless suggested by their use of those epithets, and which seems to be inconsistent with his recognition of what is now called “personal capital.” To the same source M'Culloch and others refer the origin of Smith's view, which they represent as an obvious error, that “individual advantage is not always a true test of the public advantageousness of different employments.” But that view is really quite correct, as Professor Nicholson has recently made plain. That the form taken by the use of capital, profits being given, is not indifferent to the working class as a whole even Ricardo admitted; and Cairnes, as we shall see, built on this consideration some of the most far-reaching conclusions in his *Leading Principles*.

On Smith's theory of taxation in his fifth book it is not necessary for us to dwell (see *TAXATION*). The well-known canons which he lays down as prescribing the essentials of a good system have been generally accepted. They have lately been severely criticised by Professor Walker—of whose objections, however, there is only one which appears to be well-founded. Smith seems to favor the view that the contribution of the individual to public expenses may be regarded as payment for the services rendered to him by the state, and ought to be proportional to the extent of those services. If he held this opinion, which some of his expressions imply, he was certainly so far wrong in principle.

We shall not be held to anticipate unduly if we remark here on the way in which opinion, revolted by the aberrations of some of Smith's successors, has tended to turn from the disciples to the master. A strong sense of his comparative freedom from the vicious tendencies of Ricardo and his followers has recently prompted the suggestion that we ought now to recur to Smith, and take up once more from him the line of the economical succession. But notwithstanding his indisputable superiority, and whilst fully recognizing the great services rendered by his immortal work, we must not forget that, as has been already said, that work was, on the whole, a product, though an exceptionally eminent one, of the negative philoso-

¹ Professor Bastable calls our attention to the interesting fact that the proposal of an export duty on wool and the justification of a temporary monopoly to joint-stock companies both appear for the first time in the edition of 1784.

phy of the last century, resting largely in its ultimate foundation on metaphysical bases. The mind of Smith was mainly occupied with the work of criticism so urgent in his time; his principal task was to discredit and overthrow the economic system then prevalent, and to demonstrate the radical unfitness of the existing European Governments to direct the industrial movement. This office of his fell in with, and formed a part of, the general work of demolition carried on by the thinkers who gave to the 18th century its characteristic tone. It is to his honor that, besides this destructive operation, he contributed valuable elements to the preparation of an organic system of thought and of life. In his special domain he has not merely extinguished many errors and prejudices, and cleared the ground for truth, but has left us a permanent possession in the judicious analyses of economic facts and ideas, the wise practical suggestions, and the luminous indications of all kinds, with which his work abounds. Belonging to the best philosophical school of his period, that with which the names of Hume and Diderot are associated, he tended strongly towards the positive point of view. But it was not possible for him to attain it; and the final and fully normal treatment of the economic life of societies must be constituted on other and more lasting foundations than those which underlie his imposing construction.

It has been well said that of philosophic doctrines the saying "by their fruit ye shall know them" is eminently true. And it cannot be doubted that the germs of the vicious methods and false or exaggerated theories of Smith's successors are to be found in his own work, though his good sense and practical bent prevented his following out his principles to their extreme consequences. The objections of Hildebrand and others to the entire historical development of doctrine which the Germans designate as "Smithianismus" are regarded by those critics as applicable, not merely to his school as a whole, but, though in a less degree, to himself. The following are the most important of these objections. It is said—(1) Smith's conception of the social economy is essentially individualistic. In this he falls in with the general character of the negative philosophy of his age. That philosophy, in its most typical forms, even denied the natural existence of the disinterested affections, and explained the altruistic feelings as secondary results of self-love. Smith, however, like Hume, rejected these extreme views; and hence it has been held that in the *Wealth of Nations* he consciously, though tacitly, abstracted from the benevolent principles in human nature, and as a logical artifice supposed an "economic man" actuated by purely selfish motives. However this may be, he certainly places himself habitually at the point of view of the individual, whom he treats as a purely egoistic force, working uniformly in the direction of private gain, without regard to the good of others or of the community at large. (2) He justifies this personal attitude by its consequences, presenting the optimistic view that the good of the community is best attained through the free play of individual cupidities, provided only the law prevents the interference of one member of the society with the self-seeking action of another. He assumes with the negative school generally—though he has passages which are not in harmony with these propositions—that every one knows his true interest and will pursue it, and that the economic advantage of the individual coincides with that of the society. To this last conclusion he is secretly led, as we have seen, by *a priori* theological ideas, and also by metaphysical conceptions of a supposed system of nature, natural right, and natural liberty. (3) By this reduction of every question to one of individual gain, he is led to a too exclusive consideration of exchange value as distinct from wealth in the proper sense. This, whilst lending a mechanical facility in arriving at conclusions, gives a superficial

character to economic investigation, divorcing it from the physical and biological sciences, excluding the question of real social utility, leaving no room for a criticism of production, and leading to a denial, like J. S. Mill's, of any economic doctrine dealing with consumption—in other words, with the use of wealth. (4) In condemning the existing industrial policy, he tends too much towards a glorification of non-government, and a repudiation of all social intervention for the regulation of economic life. (5) He does not keep in view the moral destination of our race, nor regard wealth as a means to the higher ends of life, and thus incurs, not altogether unjustly, the charge of materialism, in the wider sense of that word. Lastly, (6) his whole system is too absolute in its character; it does not sufficiently recognize the fact, that in the language of Hildebrand, man, as a member of society, is a child of civilization and a product of history, and that account ought to be taken of the different stages of social development as implying altered economic conditions and calling for altered economic action, or even involving a modification of the actor. Perhaps in all the respects here enumerated, certainly in some of them and notably in the last, Smith is less open to criticism than most of the later English economists; but it must, we think, be admitted that to the general principles which lie at the basis of his scheme the ultimate growth of these several vicious tendencies is traceable.

Great expectations had been entertained respecting Smith's work by competent judges before its publication, as is shown by the language of Ferguson on the subject in his *History of Civil Society*. That its merits received prompt recognition is proved by the fact of six editions having been called for within the fifteen years after its appearance.¹ From the year 1783 it was more and more quoted in parliament. Pitt was greatly impressed by its reasonings; Smith is reported to have said that that minister understood the book as well as himself. Pulteney said in 1797 that Smith would convince the then living generation and would rule the next.

Smith's earliest critics were Bentham and Lauderdale, who, though in general agreement with him, differed on special points. Jeremy Bentham was author of a short treatise entitled *A Manual of Political Economy* (1843), and various economic monographs, the most celebrated of which was his *Defence of Usury* (1787). This contained (Letter xiii.) an elaborate criticism of a passage in the *Wealth of Nations*, already cited, in which Smith had approved of a legal maximum rate of interest fixed but a very little above the lowest market rate, as tending to throw the capital of the country into the hands of sober persons, as opposed to "prodigals and projectors." Smith is said to have admitted that Bentham had made out his case. He certainly argues it with great ability; and the true doctrine no doubt is that, in a developed industrial society, it is expedient to let the rate be fixed by contract between the lender and the borrower, the law interfering only in case of fraud.

Bentham's main significance does not belong to the economic field. But, on the one hand, what is known

¹ Five editions of the *Wealth of Nations* appeared during the life of the author:—the second in 1779, the third in 1784, the fourth in 1786, and the fifth in 1789. After the third edition Smith made no change in the text of his work. The principal editions containing matter added by other economists are those by David Buchanan, with notes and an additional volume, 1834; by J. R. McCulloch, with life of the author, introductory discourse, notes, and supplemental dissertations, 1828 (also, with numerous additions, 1839; since reprinted several times, with further additions); by the author of *England and America* (Edward Gibbon Wakefield), with a commentary which, however, is not continued beyond the second book, 1835-9; by James E. Thorold Rogers, now professor of political economy at Oxford, with biographical preface and a careful verification of all Smith's quotations and references, 1869 (2d ed., 1880); and by J. S. Nicholson, professor at Edinburgh, with notes referring to sources of further information on the various topics handled in the text, 1884. There is a careful *Abridgment* by W. F. Emerton (2d ed., 1881), founded on the earlier *Analysis* of Jeremiah Joyce (3d ed., 1821).

* [An Oxford graduate, who, after publishing researches in economics, especially on prices and wages in England, died, October 12, 1890, at the age of sixty-six.—AM. Ed.]

as Benthamism was undoubtedly, as Comte has said, a derivative from political economy, and in particular from the system of natural liberty; and, on the other, it promoted the temporary ascendancy of that system by extending to the whole of social and moral theory the use of the principle of individual interest and the method of deduction from that interest. This alliance between political economy and the scheme of Bentham is seen in the personal group of thinkers which formed itself round him,—thinkers most inaptly characterized by J. S. Mill as “profound,” but certainly possessed of much acuteness and logical power, and tending, though vaguely, towards a positive sociology, which, from their want of genuinely scientific culture and their absolute and unhistorical modes of thought, they were incapable of founding.

Lord Lauderdale, in his *Inquiry into the Nature and Origin of Public Wealth* (1804), a book still worth reading, pointed out certain real weaknesses in Smith's account of value and the measure of value, and of the productivity of labor, and threw additional light on several subjects, such as the true mode of estimating the national income, and the reaction of the distribution of wealth on its production.

Smith stood just at the beginning of a great industrial revolution. The world of production and commerce in which he lived was still, as Cliffe Leslie has said, a “very early” and comparatively narrow one; “the only steam-engine he refers to is Newcomen's,” and the cotton trade is mentioned by him only once, and that incidentally. “Between the years 1760 and 1770,” says Mr. Marshall, “Roebuck began to smelt iron by coal, Brindley connected the rising seats of manufactures with the sea by canals, Wedgwood discovered the art of making earthenware cheaply and well, Hargreaves invented the spinning jenny, Arkwright utilized Wyatt's and High's inventions for spinning by rollers and applied water power to move them, and Watt invented the condensing steam-engine. Crompton's mule and Cartwright's power-loom came shortly after.” Out of this rapid evolution followed a vast expansion of industry, but also many deplorable results, which, had Smith been able to foresee them, might have made him a less enthusiastic believer in the benefits to be wrought by the mere liberation of effort, and a less vehement denouncer of old institutions which in their day had given a partial protection to labor. Alongside of these evils of the new industrial system, socialism appeared as the alike inevitable and indispensable expression of the protest of the working-classes and the aspiration after a better order of things; and what we now call “the social question,” that inexorable problem of modern life, rose into the place which it has ever since maintained. This question was first effectually brought before the English mind by Thomas Robert Malthus (1766–1834), not however, under the impulse of revolutionary sympathies, but in the interests of a conservative policy.

The first edition of the work which achieved this result appeared anonymously in 1798 under the title—*An Essay on the Principle of Population, as it affects the future improvement of Society, with remarks on the speculations of Mr. Godwin, M. Condorcet, and other writers*. This book arose out of certain private controversies of its author with his father Daniel Malthus, who had been a friend of Rousseau, and was an ardent believer in the doctrine of human progress as preached by Condorcet and other French thinkers and by their English disciples. The most distinguished of the latter was William Godwin, whose *Enquiry concerning Political Justice* had been published in 1793. The views put forward in that work had been restated by its author in the *Enquirer* (1797), and it was on the essay in this volume entitled “Avarice and Profusion” that the discussion between the father and the son arose, “the general question of the future improvement of society” being thus raised between them—the elder Malthus

defending the doctrines of Godwin, and the younger assailing them. The latter “sat down with an intention of merely stating his thoughts on paper in a clearer manner than he thought he could do in conversation,” and the *Essay* on population was the result.

The social scheme of Godwin was founded on the idea that the evils of society arise from the vices of human institutions. There is more than enough of wealth available for all, but it is not equally shared: one has too much, another has little or nothing. Let this wealth, as well as the labor of producing it, be equally divided; then every one will by moderate exertion obtain sufficient for plain living; there will be abundant leisure, which will be spent in intellectual and moral self-improvement; reason will determine human actions; government and every kind of force will be unnecessary; and, in time, by the peaceful influence of truth, perfection and happiness will be established on earth. To these glowing anticipations Malthus opposes the facts of the necessity of food, and the tendency of mankind to increase up to the limit of the available supply of it. In a state of universal physical well-being, this tendency, which in real life is held in check by the difficulty of procuring a subsistence, would operate without restraint. Scarcity would follow the increase of numbers; the leisure would soon cease to exist; the old struggle for life would recommence; and inequality would reign once more. If Godwin's ideal system, therefore, could be established, the single force of the principle of population, Malthus maintained, would suffice to break it down.

It will be seen that the essay was written with a polemical object; it was an occasional pamphlet directed against the utopias of the day, not at all a systematic treatise on population suggested by a purely scientific interest. As a polemic, it was decidedly successful; it was no difficult task to dispose of the scheme of equality propounded by Godwin. Already, in 1761, Dr. Robert Wallace had published a work (which was used by Malthus in the composition of his essay) entitled *Various Prospects of Mankind, Nature, and Providence*, in which, after speaking of a community of goods as a remedy for the ills of society, he confessed that he saw one fatal objection to such a social organization, namely, “the excessive population that would ensue.” With Condorcet's extravagances, too, Malthus easily dealt. That eminent man, amidst the tempest of the French Revolution, had written, whilst in hiding from his enemies, his *Esquisse d'un tableau historique de l'esprit humain*. The general conception of this book makes its appearance an epoch in the history of the rise of sociology. In it, if we except some partial sketches by Turgot, is for the first time explained the idea of a theory of social dynamics founded on history; and its author is on this ground recognized by Comte as his principal immediate predecessor. But in the execution of his great project Condorcet failed. His negative metaphysics prevent his justly appreciating the past, and he indulges, at the close of his work, in vague hypotheses respecting the perfectibility of our race, and in irrational expectations of an indefinite extension of the duration of human life. Malthus seems to have little sense of the nobleness of Condorcet's attitude, and no appreciation of the grandeur of his leading idea. But of his chimerical hopes he is able to make short work; his good sense, if somewhat limited and prosaic, is at least effectual in detecting and exposing utopias.

The project of a formal and detailed treatise on population was an afterthought of Malthus. The essay in which he had studied a hypothetical future led him to examine the effects of the principle he had put forward on the past and present state of society; and he undertook an historical examination of these effects, and sought to draw such inferences in relation to the actual state of things as experience seemed to warrant. The consequence of this was such a change in the

nature and composition of the essay as made it, in his own language, "a new work." The book, so altered, appeared in 1803 under the title—*An Essay on the Principle of Population, or a view of its Past and Present Effects on Human Happiness; with an Enquiry into our prospects respecting the future removal or mitigation of the evils which it occasions.*

In the original form of the essay he had spoken of no checks to population but those which came under the head either of vice or of misery. He now introduces the new element of the preventive check supplied by what he calls "moral restraint," and is thus enabled to "soften some of the harshest conclusions" at which he had before arrived. The treatise passed through six editions in his lifetime, and in all of them he introduced various additions and corrections. That of 1816 is the last he revised, and supplies the final text from which it has since been reprinted.

Notwithstanding the great development which he gave to his work and the almost unprecedented amount of discussion to which it gave rise, it remains a matter of some difficulty to discover what solid contribution he has made to our knowledge, nor is it easy to ascertain precisely what practical precepts, not already familiar, he founded on his theoretic principles. This twofold vagueness is well brought out in his celebrated correspondence with Senior, in the course of which it seems to be made apparent that his doctrine is new not so much in its essence as in the phraseology in which it is couched. He himself tells us that when, after the publication of the original essay, the main argument of which he had deduced from Hume, Wallace, Smith, and Price, he began to inquire more closely into the subject, he found that "much more had been done" upon it "than he had been aware of." It had "been treated in such a manner by some of the French economists, occasionally by Montesquieu, and, among our own writers, by Dr. Franklin, Sir James Steuart, Mr. Arthur Young, and Mr. Townsend, as to create a natural surprise that it had not excited more of the public attention." "Much, however," he thought, "remained yet to be done. The comparison between the increase of population and food had not, perhaps, been stated with sufficient force and precision," and "few inquiries had been made into the various modes by which the level" between population and the means of subsistence "is effected." The first desideratum here mentioned—the want, namely, of an accurate statement of the relation between the increase of population and food—Malthus doubtless supposed to have been supplied by the celebrated proposition that "population increases in a geometrical, food in an arithmetical ratio." This proposition, however, has been conclusively shown to be erroneous, there being no such difference of law between the increase of man and that of the organic beings which form his food. J. S. Mill is indignant with those who criticise Malthus's formula, which he groundlessly describes as a mere "passing remark," because, as he thinks, though erroneous, it sufficiently suggests what is true; but it is surely important to detect unreal science, and to test strictly the foundations of beliefs. When the formula which we have cited is not used, other somewhat nebulous expressions are sometimes employed, as, for example, that "population has a tendency to increase faster than food," a sentence in which both are treated as if they were spontaneous growths, and which, on account of the ambiguity of the word "tendency," is admittedly consistent with the fact asserted by Senior, that food tends to increase faster than population. It must always have been perfectly well known that population will probably (though not necessarily) increase with every augmentation of the supply of subsistence, and may, in some instances, inconveniently press upon, or even for a certain time exceed, the number properly corresponding to that supply. Nor could it ever have been doubted that war, disease, poverty—the last two often the consequences of vice—are causes which keep

population down. In fact, the way in which abundance, increase of numbers, want, increase of deaths, succeed each other in the natural economy, when reason does not intervene, had been fully explained by the Rev. Joseph Townsend in his *Dissertation on the Poor Laws* (1786), which was known to Malthus. Again, it is surely plain enough that the apprehension by individuals of the evils of poverty, or a sense of duty to their possible offspring, may retard the increase of population, and has in all civilized communities operated to a certain extent in that way. It is only when such obvious truths are clothed in the technical terminology of "positive" and "preventive checks" that they appear novel and profound; and yet they appear to contain the whole message of Malthus to mankind. The laborious apparatus of historical and statistical facts respecting the several countries of the globe, adduced in the altered form of the essay, though it contains a good deal that is curious and interesting, establishes no general result which was not previously well known, and is accordingly ignored by James Mill and others, who rest the theory on facts patent to universal observation. Indeed, as we have seen, the entire historical inquiry was an afterthought of Malthus, who, before entering on it, had already announced his fundamental principle.

It would seem, then, that what has been ambitiously called Malthus's theory of population, instead of being a great discovery, as some have represented it, or a poisonous novelty, as others have considered it, is no more than a formal enunciation of obvious, though sometimes neglected, facts. The pretentious language often applied to it by economists is objectionable, as being apt to make us forget that the whole subject with which it deals is as yet very imperfectly understood—the causes which modify the force of the sexual instinct, and those which lead to variations in fecundity, still awaiting a complete investigation.

It is the law of diminishing returns from land (of which we shall hear more hereafter), involving as it does—though only hypothetically—the prospect of a continuously increasing difficulty in obtaining the necessary sustenance for all the members of a society, that gives the principal importance to population as an economic factor. It is, in fact, the confluence of the Malthusian ideas with the theories of Ricardo, especially with the corollaries which the latter, as we shall see, deduced from the doctrine of rent (though these were not accepted by Malthus), that has led to the introduction of population as an element in the discussion of so many economic questions in recent times.

Malthus had undoubtedly the great merit of having called public attention in a striking and impressive way to a subject which had neither theoretically nor practically been sufficiently considered. But he and his followers appear to have greatly exaggerated both the magnitude and the urgency of the dangers to which they pointed.¹ In their conceptions a single social imperfection assumed such portentous dimensions that it seemed to overcloud the whole heaven and threaten the world with ruin. This doubtless arose from his having at first omitted altogether from his view of the question the great counteracting agency of moral restraint. Because a force exists, capable, if unchecked, of producing certain results, it does not follow that those results are imminent or even possible in the sphere of experience. A body thrown from the hand would, under the single impulse of projection, move forever in a straight line; but it would not be reasonable to take special action for the prevention of this result, ignoring the fact that it will be sufficiently counteracted by the other forces which will come into play. And such other forces exist in the case we are considering. If the inherent energy of the principle of population (supposed everywhere the same) is measured by

¹ Malthus himself said, "It is probable that, having found the bow bent too much one way, I was induced to bend it too much the other in order to make it straight."

the rate at which numbers increase under the most favorable circumstances, surely the force of less favorable circumstances, acting through prudential or altruistic motives, is measured by the great difference between this maximum rate and those which are observed to prevail in most European countries. Under a rational system of institutions, the adaptation of numbers to the means available for their support is effected by the felt or anticipated pressure of circumstances and the fear of social degradation, within a tolerable degree of approximation to what is desirable. To bring the result nearer to the just standard, a higher measure of popular enlightenment and more serious habits of moral reflection ought indeed to be encouraged. But it is the duty of the individual to his possible offspring, and not any vague notions as to the pressure of the national population on subsistence, that will be adequate to influence conduct.

The only obligation on which Malthus insists is that of abstinence from marriage so long as the necessary provision for a family has not been acquired or cannot be reasonably anticipated. The idea of post-nuptial continence, which has since been put forward by J. S. Mill and others, is foreign to his view. He even suggests that an allowance might be made from the public funds for every child in a family beyond the number of six, on the ground that when a man marries, he cannot tell how many children he shall have, and that the relief from an unlooked-for distress afforded by such a grant would not operate as an encouragement to marriage. The duty of economic prudence in entering on the married state is plain; but in the case of workmen the idea of a secured provision must not be unduly pressed, and it must also be remembered that the proper age for marriage in any class depends on the duration of life in that class. Too early marriages, however, are certainly not infrequent, and they are attended with other than material evils, so that possibly even legal measures might with advantage be resorted to for preventing them in all ranks by somewhat postponing the age of full civil competence. On the other hand, however, the Malthusians often speak too lightly of involuntary celibacy, not recognizing sufficiently that it is a deplorable necessity. They do not adequately estimate the value of domestic life as a school of the civic virtues, and the social importance (even apart from personal happiness) of the mutual affective education arising from the relations of the sexes in a well-constituted union.

Malthus further infers from his principles that states should not artificially stimulate population, and in particular that poor-laws should not be established, and, where they exist, should be abolished. The first part of this proposition cannot be accepted as applying to every social phase, for it is evident that in a case like that of ancient Rome, where continuous conquest was the chief occupation of the national activity, or in other periods when protracted wars threatened the independence or security of nations, statesmen might wisely take special action of the kind deprecated by Malthus. In relation to modern industrial communities he is doubtless in general right, though the promotion of immigration in new states is similar in principle to the encouragement of population. The question of poor-laws involves other considerations. The English system of his day was certainly a vicious one, though acting in some degree as a corrective of other evils in our social institutions; and efforts for its amendment tended to the public good. But the proposal of abolition is one from which statesmen have recoiled, and which general opinion has never adopted. It is difficult to believe that the present system will be permanent; it is too mechanical and indiscriminating; on some sides too lax, it is often unduly rigorous in the treatment of the worthy poor who are the victims of misfortune; and, in its ordinary modes of dealing with the young, it is open to grave objection. But it would certainly be rash to abolish it; it is one of several institutions which will more wisely be retained until the whole subject of the life of the working classes has been more thoroughly, and also more sympathetically, studied. The position of Malthus with respect to the relief of destitution is subject to this general criticism that, first proving too much, he then shrinks from the consequences of his own logic. It follows from his arguments, and is indeed explicitly stated in a celebrated passage of his original essay, that he who has brought children into the world without adequate provision for them should be left to the punishment of Nature, that "it is a miserable ambition to wish to snatch the rod from her hand," and to defeat the action of her laws, which are the laws of God, and which "have doomed him and his family to suffer." Though his theory

leads him to this conclusion, he could not, as a Christian clergyman, maintain the doctrine that, seeing our brother in need, we ought to shut up our bowels of compassion from him; and thus he is involved in the radical inconsequence of admitting the lawfulness, if not the duty, of relieving distress, whilst he yet must regard the act as doing mischief to society. Buckle, who was imposed on by more than one of the exaggerations of the economists, accepts the logical inference which Malthus evaded. He alleges that the only ground on which we are justified in relieving destitution is the essentially self-regarding one, that by remaining deaf to the appeal of the sufferer we should probably blunt the edge of our own finer sensibilities.

It can scarcely be doubted that the favor which was at once accorded to the views of Malthus in certain circles was due in part to an impression, very welcome to the higher ranks of society, that they tended to relieve the rich and powerful of responsibility for the condition of the working classes, by showing that the latter had chiefly themselves to blame, and not either the negligence of their superiors or the institutions of the country. The application of his doctrines, too, made by some of his successors had the effect of discouraging all active effort for social improvement. Thus Chalmers "reviews *seriatim* and gravely sets aside all the schemes usually proposed for the amelioration of the economic condition of the people" on the ground that an increase of comfort will lead to an increase of numbers, and so the last state of things will be worse than the first.

Malthus has in more recent times derived a certain degree of reflected lustre from the rise and wide acceptance of the Darwinian hypothesis. Its author himself, in tracing its filiation, points to the phrase "struggle for existence" used by Malthus in relation to the social competition. Darwin believes that man has advanced to his present high condition through such a struggle, consequent on his rapid multiplication. He regards, it is true, the agency of this cause for the improvement of our race as largely superseded by moral influences in the more advanced social stages. Yet he considers it even in these stages, of so much importance towards that end that, notwithstanding the individual suffering arising from the struggle for life, he deprecates any great reduction in the natural, by which he seems to mean the ordinary, rate of increase.

There has been of late exhibited in some quarters a tendency to apply the doctrine of the "survival of the fittest" to human society in such a way as to intensify the harsher features of Malthus's exposition by encouraging the idea that whatever cannot sustain itself is fated, and must be allowed to disappear. But what is repellent in this conception is removed by a wider view of the influence of Humanity, as the presiding race, alike on vital and on social conditions. As in the general animal domain the supremacy of man introduces a new force consciously controlling and ultimately determining the destinies of the subordinate species, so human providence in the social sphere can intervene for the protection of the weak, modifying by its deliberate action what would otherwise be a mere contest of comparative strengths inspired by selfish instincts.

David Ricardo (1772-1823) is essentially of the school of Smith, whose doctrines he in the main accepts, whilst he seeks to develop them, and to correct them in certain particulars. But his mode of treatment is very different from Smith's. The latter aims at keeping close to the realities of life as he finds them,—at representing the conditions and relations of men and things as they are; and, as Hume remarked on first reading his great work, his principles are everywhere exemplified and illustrated with curious facts. Quite unlike this is the way in which Ricardo proceeds. He moves in a world of abstractions. He sets out from more or less arbitrary assumptions, reasons deductively from these, and announces his conclusions as true, without allowing for the partial un-

reality of the conditions assumed or confronting his results with experience. When he seeks to illustrate his doctrines it is from hypothetical cases,—his favorite device being that of imagining two contracting savages, and considering how they would be likely to act. He does not explain—probably he had not systematically examined, perhaps was not competent to examine—the appropriate method of political economy, and the theoretic defence of his mode of proceeding was left to be elaborated by J. S. Mill and Cairnes. But his example had a great effect in determining the practice of his successors. There was something highly attractive to the ambitious theorist in the sweeping march of logic which seemed in Ricardo's hands to emulate the certainty and comprehensiveness of mathematical proof, and in the portable and pregnant formulæ which were so convenient in argument, and gave a prompt, if often a more apparent than real, solution of difficult problems. Whatever there was of false or narrow in the fundamental positions of Smith had been in a great degree corrected by his practical sense and strong instinct for reality, but was brought out in its full dimensions and even exaggerated in the abstract theorems of Ricardo and his followers.

The dangers inherent in his method were aggravated by the extreme looseness of his phraseology. Senior pronounces him "the most incorrect writer who ever attained philosophical eminence." His most ardent admirers find him fluctuating and uncertain in the use of words, and generally trace his errors to a confusion between the ordinary employment of a term and some special application of it which he has himself devised.

The most complete exposition of his system is to be found in his *Principles of Political Economy and Taxation* (1817). This work is not a complete treatise on the science, but a rather loosely connected series of disquisitions on value and price, rent, wages and profits, taxes, trade, money and banking. Yet, though the connection of the parts is loose, the same fundamental ideas recur continually, and determine the character of the entire scheme.

The principal problem to which he addresses himself in this work is that of distribution,—that is to say, the proportions of the whole produce of the country which will be allotted to the proprietor of land, to the capitalist, and to the laborer. And it is important to observe that it is especially the variations in their respective portions which take place in the progress of society that he professes to study,—one of the most unhistorical of writers thus indicating a sense of the necessity of a doctrine of economic dynamics—a doctrine which, from his point of view, it was impossible to supply.

The principle which he puts first in order, and which is indeed the key to the whole, is this—that the exchange value of any commodity the supply of which can be increased at will is regulated, under a régime of free competition, by the labor necessary for its production. Similar propositions are to be found in the *Wealth of Nations*, not to speak of earlier English writings. Smith had said that, "in the early and rude state of society which precedes both the accumulation of stock and the appropriation of land, the proportion between the quantities of labor necessary for acquiring different objects seems to be the only circumstance which can afford any rule for exchanging them with one another." But he wavers in his conception, and presents as the measure of value sometimes the quantity of labor necessary for the production of the object, sometimes the quantity of labor which the object would command in the market, which are identical only for a given time and place. The theorem requires correction for a developed social system by the introduction of the consideration of capital, and takes the form in which it is elsewhere quoted from Malthus by Ricardo, that the real price of a commodity "depends on the greater or less quantity of capital and labor which must be employed to produce it." (The expression "quantity of capital" is lax, the element of time being omitted, but the meaning is obvious). Ricardo, however, constantly takes no notice of capital, mentioning labor alone in his statement of this principle, and seeks to justify

his practice by treating capital as "accumulated labor"; but this artificial way of viewing the facts obscures the nature of the co-operation of capital in production, and by keeping the necessity of this co-operation out of sight has encouraged some socialistic errors. Ricardo does not sufficiently distinguish between the cause or determinant and the measure of value; nor does he carry back the principle of cost of production as regulator of value to its foundation in the effect of that cost on the limitation of supply. It is the "natural price" of a commodity that is fixed by the theorem we have stated; the market price will be subject to accidental and temporary variations from this standard, depending on changes in demand and supply; but the price will, permanently and in the long run, depend on cost of production defined as above. On this basis Ricardo goes on to explain the laws according to which the produce of the land and the labor of the country is distributed amongst the several classes which take part in production.

The theory of rent, with which he begins, though commonly associated with his name, and though it certainly forms the most vital part of his general economic scheme, was not really his, nor did he lay claim to it. He distinctly states in the preface to the *Principles*, that "in 1815 Mr. Malthus, in his *Inquiry into the Nature and Progress of Rent*, and a fellow of University College, Oxford, in his *Essay on the Application of Capital to Land*, presented to the world, nearly at the same moment, the true doctrine of rent." The second writer here referred to was Sir Edward West, afterwards a judge of the supreme court of Bombay. Still earlier than the time of Malthus and West, as McCulloch has pointed out, this doctrine had been clearly conceived and fully stated by Dr. James Anderson in his *Enquiry into the Nature of Corn-Laws*, published at Edinburgh in 1777. That this tract was unknown to Malthus and West we have every reason to believe; but the theory is certainly as distinctly enunciated and as satisfactorily supported in it as in their treatises; and the whole way in which it is put forward by Anderson strikingly resembles the form in which it is presented by Ricardo.

The essence of the theory is that rent, being the price paid by the cultivator to the owner of land for the use of its productive powers, is equal to the excess of the price of the produce of the land over the cost of production on that land. With the increase of population, and therefore of demand for food, inferior soils will be taken into cultivation; and the price of the entire supply necessary for the community will be regulated by the cost of production of that portion of the supply which is produced at the greatest expense. But for the land which will barely repay the cost of cultivation no rent will be paid. Hence the rent of any quality of land will be equal to the difference between the cost of production on that land and the cost of production of that produce which is raised at the greatest expense.

The doctrine is perhaps most easily apprehended by means of the supposition here made of the coexistence in a country of a series of soils of different degrees of fertility which are successively taken into cultivation as population increases. But it would be an error to believe, though Ricardo sometimes seems to imply it, that such difference is a necessary condition of the existence of rent. If all the land of a country were of equal fertility, still if it were appropriated, and if the price of the produce were more than an equivalent for the labor and capital applied to its production, rent would be paid. This imaginary case, however, after using it to clear our conceptions, we may for the future leave out of account.

The price of produce being, as we have said, regulated by the cost of production of that which pays no rent, it is evident that "corn is not high because a rent is paid, but a rent is paid because corn is high," and that "no reduction would take place in the price of corn although landlords should forego the whole of their rent." Rent is, in fact, no determining element of price; it is paid, indeed, out of the price, but the price would be the same if no rent were paid, and the whole price were retained by the cultivator.

It has often been doubted whether or not Adam Smith held this theory of rent. Sometimes he uses language which seems to imply it, and states propositions which, if developed, would infallibly lead to it. Thus he says, in a passage already quoted, "such parts only of the produce of land can commonly be brought to market of which the ordinary price is sufficient to replace the stock which must be employed in bringing them thither, together with its ordinary profits. If the ordinary price is more than this, the surplus part of it will naturally go to the rent of land. If it is not more, though the commodity can be brought to market, it can afford no rent to the landlord. Whether the price is or is not more depends on the demand." Again, in Smith's application of these considerations to mines,

"the whole principle of rent," Ricardo tells us, "is admirably and perspicuously explained." But he had formed the opinion that there is in fact no land which does not afford a rent to the landlord; and, strangely, he seems not to have seen that this appearance might arise from the aggregation into an economic whole of parcels of land which can and others which cannot pay rent. The truth, indeed, is that the fact, if it were a fact, that all the land in a country pays rent would be irrelevant as an argument against the Andersonian theory, for it is the same thing in substance if there be any capital employed on land already cultivated which yields a return no more than equal to ordinary profits. Such last-employed capital cannot afford rent at the existing rate of profit, unless the price of produce should rise.

The belief which some have entertained that Smith, notwithstanding some vague or inaccurate expressions, really held the Andersonian doctrine, can scarcely be maintained when we remember that Hume, writing to him after having read for the first time the *Wealth of Nations*, whilst expressing general agreement with his opinions, said (apparently with reference to bk. I. chap. vii.), "I cannot think that the rent of farms makes any part of the price of the produce, but that the price is determined altogether by the quantity and the demand." It is further noteworthy that a statement of the theory of rent is given in the same volume, published in 1777, which contains Anderson's polemic against Smith's objections to a bounty on the exportation of corn; this volume can hardly have escaped Smith's notice, yet neither by its contents nor by Hume's letter was he led to modify what he had said in his first edition on the subject of rent.

It must be remembered that not merely the unequal fertilities of different soils will determine differences of rent; the more or less advantageous situation of a farm in relation to markets, and therefore to roads and railways, will have a similar effect. Every diminution of the cost of transit will enable the produce to be brought to market at a smaller expense, and will thus increase the surplus which constitutes rent. This consideration is indicated by Ricardo, though he does not give it prominence, but dwells mainly on the comparative productiveness of soils.

Rent is defined by Ricardo as the price paid for the use of "the original and indestructible powers of the soil." He thus differentiates rent, as he uses the term, from what is popularly designated by the word; and, when it is to be taken in his sense, it is often qualified as the "true" or "economic" rent. Part of what is paid to the landlord is often really profit on his expenditure in preparing the farm for cultivation by the tenant. But it is to be borne in mind that wherever such improvements are "amalgamated with the land" and "add permanently to its productive powers," the return for them follows the laws, not of profit, but of rent. Hence it becomes difficult, if not impossible, in practice to discriminate with any degree of accuracy the amount received by the landlord "for the use of the original powers of the soil" from the amount received by him as remuneration for his improvements or those made by his predecessors. These have raised the farm, as an instrument for producing food, from one class of productiveness to a higher, and the case is the same as if nature had originally placed the land in question in that higher class.

Smith had treated it as the peculiar privilege of agriculture, as compared with other forms of production, that in it "nature labors along with man," and therefore, whilst the workmen in manufactures occasion the reproduction merely of the capital which employs them with its owner's profits, the agricultural laborer occasions the reproduction, not only of the employer's capital with profits, but also of the rent of the landlord. This last he viewed as the free gift of nature which remained "after deducting or compensating everything which can be regarded as the work of man." Ricardo justly observes in reply that "there is not a manufacture which can be mentioned in which nature does not give her assistance to man." He then goes on to quote from Buchanan the remark that "the notion of agriculture yielding a produce and a rent in consequence, because nature concurs with industry in the process of cultivation, is a mere fancy. It is not from the produce, but from the price at which the produce is sold, that the rent is derived, and this price is got, not because nature assists in the production, but because it is the price which suits the consumption to the supply."¹ There is no

gain to the society at large from the rise of rent; it is advantageous to the landlords alone, and their interests are thus permanently in opposition to those of all other classes. The rise of rent may be retarded or prevented, or even temporarily changed to a fall by agricultural improvements, such as the introduction of new manures or of machines or of a better organization of labor (though there is not so much room for this last as in other branches of production), or the opening of new sources of supply in foreign countries; but the tendency to a rise is constant so long as the population increases.

The great importance of the theory of rent in Ricardo's system arises from the fact that he makes the general economic condition of the society to depend altogether on the position in which agricultural exploitation stands. This will be seen from the following statement of his theory of wages and profits. The produce of every expenditure of labor and capital being divided between the laborer and the capitalist, in proportion as one obtains more the other will necessarily obtain less. The productiveness of labor being given, nothing can diminish profit but a rise of wages, or increase it but a fall of wages. Now the price of labor, being the same as its cost of production, is determined by the price of the commodities necessary for the support of the laborer. The price of such manufactured articles as he requires has a constant tendency to fall, principally by reason of the progressive application of the division of labor to their production. But the cost of his maintenance essentially depends, not on the price of those articles, but on that of his food, and as the production of food will in the progress of society and of population require the sacrifice of more and more labor, its price will rise, money wages will consequently rise, and with the rise of wages profits will fall. Thus it is to the necessary gradual descent to inferior soils or less productive expenditure on the same soil that the decrease in the rate of profit which has historically taken place is to be attributed (Smith ascribed this decrease to the competition of capitalists, though in one place, book I. chap. ix., he had a glimpse of the Ricardian view). This gravitation of profits towards a minimum is happily checked at times by improvements of the machinery employed in the production of necessities, and especially by such discoveries in agriculture and other causes as reduce the cost of the prime necessary of the laborer; but, here again, the tendency is constant. Whilst the capitalist thus loses, the laborer does not gain; his increased money wages only enable him to pay the increased price of his necessities, of which he will have no greater and probably a less share than he had before. In fact, the laborer can never for any considerable time earn more than what is required to enable the class to subsist in such a degree of comfort as custom has made indispensable to them, and to perpetuate their race without either increase or diminution. That is the "natural" price of labor, and if the market rate temporarily rises above it population will be stimulated and the rate of wages will again fall. Thus, whilst rent has a constant tendency to rise and profit to fall, the rise or fall of wages will depend on the rate of increase of the working classes. For the improvement of their condition Ricardo thus has to fall back on the Malthusian remedy, of the effective application of which he does not, however, seem to have much expectation. The securities against a superabundant population to which he points are the gradual abolition of the poor laws—for their amendment would not content him—and the development amongst the working classes of a taste for greater comforts and enjoyments.

It will be seen that the socialists have somewhat exaggerated in announcing, as Ricardo's "iron law" of wages, their absolute identity with the amount necessary to sustain the existence of the laborer and enable him to continue the race. He recognizes the influence of a "standard of living" as limiting the increase of the numbers of the working classes, and so keeping their wages above the lowest point. But he also holds that, in long-settled countries, in the ordinary course of human affairs and in the absence of special efforts restricting the growth of population, the condition of the laborer will decline as surely, and from the same causes, as that of the landlord will be improved.

If we are asked whether this doctrine of rent, and the consequences which Ricardo deduced from it, are true, we must answer that they are hypothetically true in the most advanced industrial communities, and there only (though they have been rashly applied to the cases of India and Ireland), but that even in those communities neither safe inference nor sound action can be built upon them. As we shall see hereafter, the value of most of the theorems of the classical economics is a good deal attenuated by the habitual assumptions that we are dealing with "economic men," actuated by one principle only; that custom, as against

¹ Senior, however, has pointed out that Smith is partly right; whilst it is true that rent is demanded because the productive powers of nature are limited and increased population requires a less remunerative expenditure in order to obtain the necessary supply, on the other hand, it is the power which most land possesses of producing the subsistence of more persons than are required for its cultivation that supplies the fund out of which rent can be paid.

competition, has no existence; that there is no such thing as combination; that there is equality of contract between the parties to each transaction, and that there is a definite universal rate of profit and wages in a community, which implies that the capital embarked in any undertaking will pass at once to another in which larger profits are for the time to be made; that a laborer, whatever his local ties of feeling, family, habit or other engagements, will transfer himself immediately to any place where, or employment in which, for the time, larger wages are to be earned than those he had previously obtained; and that both capitalists and laborers have a perfect knowledge of the condition and prospects of industry throughout the country, both in their own and other occupations. But in Ricardo's speculations on rent and its consequences there is still more of abstraction. The influence of emigration, which has assumed vast dimensions since his time, is left out of account, and the amount of land at the disposal of a community is supposed limited to its own territory, whilst contemporary Europe is in fact largely fed by the Western States of America. He did not adequately appreciate the degree in which the augmented productiveness of labor, whether from increased intelligence, improved organization, introduction of machinery, or more rapid and cheaper communication, steadily keeps down the cost of production. To these influences must be added those of legal reforms in tenure and fairer conditions in contracts, which operate in the same direction. As a result of all these causes, the pressure anticipated by Ricardo is not felt, and the cry is rather of the landlords over falling rents than of the consumer over rising prices. The entire conditions are in fact so altered that Prof. Nicholson, no enemy to the "orthodox" economics, when recently conducting an inquiry into the present state of the agricultural question, pronounced the so-called Ricardian theory of rent "too abstract to be of practical utility."

A particular economic subject on which Ricardo has thrown a useful light is the nature of the advantages derived from foreign commerce and the conditions under which such commerce can go on. Whilst preceding writers had represented those benefits as consisting in affording a vent for surplus produce, or enabling a portion of the national capital to replace itself with a profit, he pointed out that they consist, "simply and solely in this, that it enables each nation to obtain, with a given amount of labor and capital, a greater quantity of all commodities taken together." This is no doubt the point of view at which we should habitually place ourselves; but the other forms of expression employed by his predecessors are sometimes useful as representing real considerations affecting national production, and need not be absolutely disused. Ricardo proceeds to show that what determines the purchase of any commodity from a foreign country is not the circumstance that it can be produced there with less labor and capital than at home. If we have a greater positive advantage in the production of some other article than in that of the commodity in question, even though we have an advantage in producing the latter, it may be our interest to devote ourselves to the production of that in which we have the greatest advantage and to import that in producing which we should have a less, though a real, advantage. It is, in short, not absolute cost of production, but comparative cost, which determines the interchange. This remark is just and interesting, though an undue importance seems to be attributed to it by J. S. Mill and Cairnes, the latter of whom magniloquently describes it as "sounding the depths" of the problem of international dealings—though, as we shall see hereafter, he modifies it by the introduction of certain considerations respecting the conditions of domestic production.

For the nation as a whole, according to Ricardo, it is not the gross produce of the land and labor, as Smith seems to assert, that is of importance, but the net income—the excess, that is, of this produce over the cost of production, or, in other words, the amount of its rent and its profits; for the wages of labor, not essentially exceeding the maintenance of the laborers, are by him considered only as a part of the "necessary expenses of production." Hence it follows, as he himself in a characteristic and often quoted passage says, that, "provided the net real income of the nation be the same, it is of no importance whether it consists of ten or twelve millions of inhabitants. If five millions of men could produce as much food and clothing as was necessary for ten millions, food and clothing for five millions would be the net revenue. Would it be of any advantage to the country that to produce this same net revenue seven millions of men should be required,—that is to say, that seven millions should be employed to produce food and clothing sufficient for twelve millions? The food and clothing of five millions would be still the net revenue. The employing a greater number of men would enable us neither to add a man to our army and navy nor to con-

tribute one guinea more in taxes." Industry is here viewed, just as by the mercantilists, in relation to the military and political power of the state, not to the maintenance and improvement of human beings, as its end and aim. The laborer, as Held has remarked, is regarded not as a member of society, but as a means to the ends of society, on whose sustenance a part of the gross income must be expended, as another part must be spent on the sustenance of horses. We may well ask, as Sismondi did in a personal interview with Ricardo, "What! is wealth then everything? are men absolutely nothing?"

On the whole, what seems to us true of Ricardo is this, that, whilst he had remarkable powers, they were not the powers best fitted for sociological research. Nature intended him rather for a mathematician of the second order than for a social philosopher. Nor had he the due previous preparation for social studies; for we must decline to accept Bagehot's idea that, though "in no high sense an educated man," he had a specially apt training for such studies in his practice as an eminently successful stockjobber. The same writer justly notices the "anxious penetration with which he follows out rarefied minutiae." But he wanted breadth of survey, a comprehensive view of human nature and human life, and the strong social sympathies which, as the greatest minds have recognized, are a most valuable aid in this department of study. On a subject like that of money, where a few elementary propositions—into which no moral ingredient enters—have alone to be kept in view, he was well adapted to succeed; but in the larger social field he is at fault. He had great deductive readiness and skill (though his logical accuracy, as Mr. Sidgwick remarks, has been greatly exaggerated). But in human affairs phenomena are so complex, and principles so constantly limit or even compensate one another, that rapidity and daring in deduction may be the greatest of dangers, if they are divorced from a wide and balanced appreciation of facts. Dialectic ability is, no doubt, a valuable gift, but the first condition for success in social investigation is to see things as they are.

A sort of Ricardo-mythos for some time existed in economic circles. It cannot be doubted that the exaggerated estimate of his merits arose in part from a sense of the support his system gave to the manufacturers and other capitalists in their growing antagonism to the old aristocracy of landowners. The same tendency, as well as his affinity to their too abstract and unhistorical modes of thought, and their eudæmonistic doctrines, recommended him to the Benthamite group, and to the so-called Philosophical Radicals generally. Brougham said he seemed to have dropped from heaven—a singular avatar, it must be owned. His real services in connection with questions of currency and banking naturally created a prepossession in favor of his more general views. But, apart from those special subjects, it does not appear that, either in the form of solid theoretic teaching or of valuable practical guidance, he has really done much for the world, whilst he admittedly misled opinion on several important questions. De Quincey's presentation of him as a great revealer of truth is now seen to be an extravagance. J. S. Mill and others speak of his "superior lights" as compared with those of Adam Smith; but his work, as a contribution to our knowledge of human society, will not bear a moment's comparison with the *Wealth of Nations*.

It is interesting to observe that Malthus, though the combination of his doctrine of population with the principles of Ricardo composed the creed for some time professed by all the "orthodox" economists, did not himself accept the Ricardian scheme. He prophesied that "the main part of the structure would not stand." "The theory," he says, "takes a partial view of the subject, like the system of the French economists; and, like that system, after having drawn into its vortex a great number of very clever men, it will be unable to support itself against the testimony

of obvious facts, and the weight of those theories which, though less simple and captivating, are more just, on account of their embracing more of the causes which are in actual operation in all economical results."

We saw that the foundations of Smith's doctrine in general philosophy were unsound, and the ethical character of his scheme in consequence injuriously affected; but his method, consisting in a judicious combination of induction and deduction, we found (so far as the statical study of economic laws is concerned) little open to objection. Mainly through the influence of Ricardo, economic method was perverted. The science was led into the mistaken course of turning its back on observation, and seeking to evolve the laws of phenomena out of a few hasty generalizations by a play of logic. The principal vices which have been in recent times not unjustly attributed to the members of the "orthodox" school were all encouraged by his example, namely: (1) the viciously abstract character of the conceptions with which they deal, (2) the abusive preponderance of deduction in their processes of research, and (3) the too absolute way in which their conclusions are conceived and enunciated.

The two works of Malthus already named are by far the most important in the history of the science. He was also author of *Principles of Political Economy* (1820), *Definitions in Political Economy*, and some minor pieces. The works of Ricardo have been collected in one volume, with a biographical notice, by J. R. McCulloch (1846).

After Malthus and Ricardo, the first of whom had fixed public attention irresistibly on certain aspects of society, and the second had led economic research into new, if questionable, paths, came a number of minor writers who were mainly their expositors and commentators, and whom, accordingly, the Germans, with allusion to Greek mythical history, designate as the Epigoni. By them the doctrines of Smith and his earliest successors were thrown into more systematic shape, limited and guarded so as to be less open to criticism, couched in a more accurate terminology, modified in subordinate particulars, or applied to the solution of the practical questions of their day.

James Mill's *Elements* (1821) deserves special notice, as exhibiting the system of Ricardo with a thorough-going rigor, a compactness of presentation, and a skill in the disposition of materials, which give to it in some degree the character of a work of art. The *a priori* political economy is here reduced to its simplest expression. J. R. McCulloch (1779-1864)¹, author of a number of laborious statistical and other compilations, criticised current economic legislation in the *Edinburgh Review* from the point of view of the Ricardian doctrine, taking up substantially the same theoretic position as was occupied at a somewhat later period by the Manchester school. He is altogether without originality, and never exhibits any philosophic elevation or breadth. His confident dogmatism is often repellent; he admitted in his later years that he had been too fond of novel opinions, and defended them with more heat and pertinacity than they deserved. It is noticeable that, though often spoken of in his own time both by those who agreed with his views, and those, like Sismondi, who differed from them, as one of the lights of the reigning school, his name is now tacitly dropped in the writings of the members of that school. Whatever may have been his partial usefulness in vindicating the policy of free trade, it is at least plain that for the needs of our social future he has nothing to offer. Nassau William Senior (1790-1864), who was professor of political economy in the university of Oxford, published, besides a number of separate lectures, a treatise on the science, which first appeared as an article in the *Encyclopædia Metropolitana*. He is a writer of a high order of merit. He made considerable contributions to the elucidation of economic principles, specially studying exactness in nomenclature and strict accuracy in deduction. His explanations on cost of production and the

way in which it affects price, on rent, on the difference between rate of wages and price of labor, on the relation between profit and wages (with special reference to Ricardo's theorem on this subject, which he corrects by the substitution of proportional for absolute amount), and on the distribution of the precious metals between different countries are particularly valuable. His new term "abstinence," invented to express the conduct for which interest is the remuneration, was useful, though not quite appropriate, because negative in meaning. It is on the question of wages that Senior is least satisfactory. He makes the average rate in a country (which, we must maintain, is not a real quantity, though the rate in a given employment and neighborhood is) to be expressed by the fraction of which the numerator is the amount of the wages fund (an unascertainable and indeed, except as actual total of wages paid, imaginary sum) and the denominator the number of the working population; and from this he proceeds to draw the most important and far-reaching consequences, though the equation on which he founds his inferences conveys at most only an arithmetical fact, which would be true of every case of a division amongst individuals, and contains no economic element whatever. The phrase "wages fund" originated in some expressions of Adam Smith used only for the purpose of illustration, and never intended to be rigorously interpreted; and we shall see that the doctrine has been repudiated by several members of what is regarded as the orthodox school of political economy. As regards method, Senior makes the science a purely deductive one, in which there is no room for any other "facts" than the four fundamental propositions from which he undertakes to deduce all economic truth. And he does not regard himself as arriving at hypothetic conclusions; his postulates and his inferences are alike conceived as corresponding to actual phenomena. Colonel Robert Torrens (1780-1864) was a prolific writer, partly on economic theory, but principally on its applications to financial and commercial policy. Almost the whole of the programme which was carried out in legislation by Sir Robert Peel had been laid down in principle in the writings of Torrens. He gave substantially the same theory of foreign trade which was afterwards stated by J. S. Mill in one of his *Essays on Unsettled Questions*. He was an early and earnest advocate of the repeal of the corn laws, but was not in favor of a general system of absolute free trade, maintaining that it is expedient to impose retaliatory duties to countervail similar duties imposed by foreign countries, and that a lowering of import duties on the productions of countries retaining their hostile tariffs would occasion an abstraction of the precious metals, and a decline in prices, profits, and wages. His principal writings of a general character were—*The Economist* [i. e., Physiocrat] refuted, 1808; *Essay on the Production of Wealth*, 1821; *Essay on the External Corn-Trade* (eulogized by Ricardo), 1827; *The Budget, a Series of Letters on Financial, Commercial, and Colonial Policy*, 1841-3. Harriet Martineau (1802-1876) popularized the doctrines of Malthus and Ricardo in her *Illustrations of Political Economy* (1832-34), a series of tales, in which there is much excellent description, but the effect of the narrative is often marred by the somewhat ponderous disquisitions here and there thrown in, usually in the form of dialogue.

Other writers who ought to be named in any history of the science are Charles Babbage, *On the Economy of Machines and Manufactures* (1832), chiefly descriptive, but also in part theoretic; William Thomas Thornton, *Overpopulation and its Remedy* (1846), *A Plea for Peasant Proprietors* (1848); *On Labor* (1869; 2d ed., 1870), Herman Merivale, *Lectures on Colonization and Colonies*, (1841-2; new ed., 1861); T. C. Benfield, *The Organization of Industry explained* (1844; 2d ed., 1848); and Edward Gibbon Wakefield, *A View of the Art of Colonization*, 1849. Thomas Chalmers, well known in other fields of thought, was author of *The Christian and Civic Economy of Large Towns* (1821-36), and *On Political Economy in Connection with the Moral State and Moral Prospects of Society* (1832); he strongly opposed any system of legal charity, and, whilst justly insisting on the primary importance of morality, industry, and thrift as conditions of popular well-being, carried the Malthusian doctrines to excess. Nor was Ireland without a share in the economic movement of the period. Whately, having been second Drummond professor of political economy at Oxford (in succession to Senior), founded (1832), when he went to Ireland as archbishop of Dublin, a similar professorship in Trinity College, Dublin. It was first held by Mountfort Longfield, afterwards judge of the Landed Estates Court, Ireland (d. 1884). He published lectures on the science generally (1834), on *Poor Laws* (1834), and on *Commerce and Absenteeism* (1835), which were marked by independence of thought and sagacious observation. He was laudably free from many of the exaggerations of his contemporaries; he

¹ [McCulloch was born in 1789 as all authorities say, and also Mr. Ingram himself says (See art. MCCULLOCH, vol. xv p. 135) that he died in his seventy-sixth year.—AM. ED.]

said, in 1835, "in political economy we must not abstract too much," and protested against the assumption too often made that "men are guided in all their conduct by a prudent regard to their own interest." James A. Lawson¹ (now Mr. Justice Lawson) also published some lectures (1844) delivered from the same chair, which may still be read with interest and profit; his discussion of the question of population is especially good; he also asserted against Senior that the science is *avide de faits*, and that it must reason about the world and mankind as they really are.

The most systematic and thorough-going contemporary critic of the Ricardian system was Richard Jones (1790-1855), professor at Haileybury. Jones has received scant justice at the hands of his successors. J. S. Mill, whilst using his work, gave his merits but faint recognition. Even Roscher says that he did not thoroughly understand Ricardo, without giving any proof of that assertion, whilst he is silent as to the fact that much of what has been preached by the German historical school is found distinctly indicated in Jones's writings. He has been sometimes represented as having rejected the Andersonian doctrine of rent; but such a statement is incorrect. Attributing the doctrine to Malthus, he says that economist "showed satisfactorily that, when land is cultivated by capitalists living on the profits of their stock, and able to move it at pleasure to other employments, the expense of tilling the worst quality of land cultivated determines the average price of raw produce, while the difference of quality on the superior lands measures the rents yielded by them." What he really denied was the application of the doctrine to all cases where rent is paid; he pointed out in his *Essay on the Distribution of Wealth and on the Sources of Taxation*, 1831, that, besides "farmers' rents," which, under the supposed conditions, conform to the above law, there are "peasant rents," paid everywhere through the most extended periods of history, and still paid over by far the largest part of the earth's surface, which are not so regulated. Peasant rents he divided under the heads of (1) serf, (2) métayer, (3) ryot, and (4) cottier rents, a classification afterwards adopted in substance by J. S. Mill; and he showed that the contracts fixing their amount were, at least in the first three classes, determined rather by custom than by competition. Passing to the superstructure of theory erected by Ricardo on the doctrine of rent which he had so unduly extended, Jones denied most of the conclusions he had deduced, especially the following: that the increase of farmers' rents is always contemporary with a decrease in the productive powers of agriculture, and comes with loss and distress in its train; that the interests of landlords are always and necessarily opposed to the interests of the state and of every other class of society; that the diminution of the rate of profits is exclusively dependent on the returns to the capital last employed on the land; and that wages can rise only at the expense of profits.

The method followed by Jones is inductive; his conclusions are founded on a wide observation of contemporary facts, aided by the study of history. "If," he said, "we wish to make ourselves acquainted with the economy and arrangements by which the different nations of the earth produce and distribute their revenues, I really know but of one way to attain our object, and that is, to look and see. We must get comprehensive views of facts, that we may arrive at principles that are truly comprehensive. If we take a different method, if we snatch at general principles, and content ourselves with confined observations, two things will happen to us. First, what we call general principles will often be found to have no generality—we shall set out with declaring propositions to be universally true which, at every step of our further progress, we shall be obliged to confess are frequently false; and, secondly, we shall miss a great mass of useful knowledge which those who advance to principles by a comprehensive examination of facts necessarily meet with on their road." The world he professed to study was not an imaginary world, inhabited by abstract "economic men," but the real world with the different forms which the ownership and cultivation

of land, and, in general, the conditions of production and distribution, assume at different times and places. His recognition of such different systems of life in communities occupying different stages in the progress of civilization led to his proposal of what he called a "political economy of nations." This was a protest against the practice of taking the exceptional state of facts which exists, and is indeed only partially realized, in a small corner of our planet as representing the uniform type of human societies, and ignoring the effects of the early history and special development of each community as influencing its economic phenomena.

It is sometimes attempted to elude the necessity for a wider range of study by alleging a universal tendency in the social world to assume this now exceptional shape as its normal and ultimate constitution. Even if this tendency were real (which is only partially true, for the existing order amongst ourselves cannot be regarded as entirely definitive), it could not be admitted that the facts witnessed in our civilization and those exhibited in less advanced communities are so approximate as to be capable of being represented by the same formulae. As Whewell, in editing Jones's *Remains*, 1859, well observed, it is true in the physical world that "all things tend to assume a form determined by the force of gravity; the hills tend to become plains, the waterfalls to eat away their beds and disappear, the rivers to form lakes in the valleys, the glaciers to pour down in cataracts." But are we to treat these results as achieved, because forces are in operation which may ultimately bring them about? As Comte has said, all human questions are largely questions of time; and the economic phenomena which really belong to the several stages of the human movement must be studied as they are, unless we are content to fall into grievous error both in our theoretic treatment of them and in the solution of the practical problems they present.

Jones is remarkable for his freedom from exaggeration and one-sided statement; thus, whilst holding Malthus in, perhaps, undue esteem, he declines to accept the proposition that an increase of the means of subsistence is necessarily followed by an increase of population; and he maintains what is undoubtedly true, that with the growth of population, in all well-governed and prosperous states, the command over food, instead of diminishing, increases.

Much of what he has left us—a large part of which is unfortunately fragmentary—is akin to the later labors of Cliffe Leslie. The latter, however, had the advantage of acquaintance with the sociology of Comte, which gave him a firmer grasp of method, as well as a wider view of the general movement of society; and whilst the voice of Jones was but little heard amidst the general applause accorded to Ricardo in the economic world of his time, Leslie wrote when disillusion had set in, and the current was beginning to turn in England against the *a priori* economics.

Comte somewhere speaks of the "transient predilection" for political economy which had shown itself generally in western Europe. This phase of feeling was specially noticeable in England from the third to the fifth decade of the present century. "Up to the year 1818," said a writer in the *Westminster Review*, "the science was scarcely known or talked of beyond a small circle of philosophers; and legislation, so far from being in conformity with its principles, was daily receding from them more and more." Mill has told us what a change took place within a few years. "Political economy," he says, "had asserted itself with great vigor in public affairs by the petition of the merchants of London for free trade, drawn up in 1820 by Mr. Tooke and presented by Mr. Alexander Baring, and by the noble exertions of Ricardo during the few years of his parliamentary life. His writings, following up the impulse given by the bullion controversy, and followed up in their turn by the expositions and comments of my father and M'Culloch (whose writings in the *Edinburgh Review* during those years were most valuable), had drawn general attention to the subject, making at least partial converts in the cabinet itself; and Huskisson, supported by Canning, had commenced that gradual demolition of the protective system which one of their colleagues virtually completed in 1846, though the last vestiges were only swept away by Mr. Gladstone in 1860." Whilst the science was thus attracting and fixing the attention of active minds, its unsettled condition was freely admitted. The differences of opinion among its

¹ [Justice on Queen's Bench, Ireland; escaped an agrarian assassination; translated Latin hymns. Died in 1887, aged seventy years.—AM. ED.]

professors were a frequent subject of complaint. But it was confidently expected that these discrepancies would soon disappear, and Colonel Torrens predicted that in twenty years there would scarcely "exist a doubt respecting any of its more fundamental principles." "The prosperity," says Mr. Sidgwick, "that followed on the abolition of the corn laws gave practical men a most impressive and satisfying proof of the soundness of the abstract reasoning by which the expediency of free trade had been inferred," and when,

J. S. MILL. in 1848, "a masterly expositor of thought had published a skilful statement of the chief results of the controversies of the preceding generation," with the due "explanations and qualifications" of the reigning doctrines, it was for some years generally believed that political economy had "emerged from the state of polemical discussion," at least on its leading doctrines, and that at length a sound construction had been erected on permanent bases.

This expositor was John Stuart Mill (1806-73). He exercised, without doubt, a greater influence in the field of English economics than any other writer since Ricardo. His systematic treatise has been, either directly or through manuals founded on it, especially that of Fawcett, the source from which most of our contemporaries in these countries have derived their knowledge of the science. But there are other and deeper reasons, as we shall see, which make him, in this as in other departments of knowledge, a specially interesting and significant figure.

In 1844 he published five *Essays on some Unsettled Questions of Political Economy*, which had been written as early as 1829 and 1830, but had, with the exception of the fifth, remained in manuscript. In these essays is contained any dogmatic contribution which he can be regarded as having made to the science. The subject of the first is the laws of interchange between nations. He shows that, when two countries trade together in two commodities, the prices of the commodities exchanged on both sides (which, as Ricardo had proved, are not determined by cost of production) will adjust themselves in such a way that the quantities required by each country of the article which it imports from its neighbor shall be exactly sufficient to pay for one another. This is the law which appears, with some added developments, in his systematic treatise under the name of the "equation of international demand." The most important practical conclusion (not, however, by any means an undisputed one) at which he arrives in this essay is, that the relaxation of duties on foreign commodities, not operating as protection but maintained solely for revenue, should be made contingent on the adoption of some corresponding degree of freedom of trade with England by the nation from which the commodities are imported. In the second essay, on the influence of consumption on production, the most interesting results arrived at are the propositions—(1) that absenteeism is a local, not a national, evil, and (2) that, whilst there cannot be permanent excess of production, there may be a temporary excess, not only of any one article, but of commodities generally,—this last, however, not arising from over-production, but from a want of commercial confidence. The third essay relates to the use of the words "productive" and "unproductive" as applied to labor, to consumption, and to expenditure. The fourth deals with profits and interest, especially explaining and so justifying Ricardo's theorem that "profits depend on wages, rising as wages fall and falling as wages rise." What Ricardo meant was that profits depend on the cost of wages estimated in labor. Hence improvements in the production of articles habitually consumed by the laborer may increase profits without diminishing the real remuneration of the laborer. The last essay is on the definition and method of political economy, a subject afterwards more maturely treated in the author's *System of Logic*.

In 1848 Mill published his *Principles of Political Economy, with some of their Applications to Social Philosophy*. This title, though, as we shall see, open to criticism, indicated on the part of the author a less narrow and formal conception of the field of the science than had been common amongst his predecessors. He aimed, in fact, at producing a work which might replace in ordinary use the *Wealth of Nations*, which in his opinion was "in many parts obsolete and in all imperfect." Adam Smith had invariably associated the general principles of the subject with their applications, and in treating those applications had perpetually appealed to other and often far larger considerations than pure political economy affords. And in the same spirit Mill desired, whilst incorporating all the results arrived at in the special science by Smith's successors, to exhibit purely economic phenomena in relation to the most advanced conceptions of his own time in the general philosophy of society, as Smith had done in reference to the philosophy of his century.

This design he certainly failed to realize. His book is very far indeed from being a "modern Adam Smith." It is an admirably lucid and even elegant exposition of the Ricardian economics, the Malthusian theory being of course incorporated with these, but, notwithstanding the introduction of many minor novelties, it is, in its scientific substance, little or nothing more. When Cliffe Leslie says that Mill so qualified and amended the doctrines of Ricardo that the latter could scarcely have recognized them, he certainly goes a great deal too far; Senior really did more in that direction. Mill's effort is usually to vindicate his master where others have censured him, and to palliate his admitted laxities of expression. Already his profound esteem for Ricardo's services to economics had been manifest in his *Essays*, where he says of him, with some injustice to Smith, that, "having a science to create," he could not "occupy himself with more than the leading principles," and adds that "no one who has thoroughly entered into his discoveries" will find any difficulty in working out "even the minutiae of the science." James Mill, too, had been essentially an expounder of Ricardo; and the son, whilst greatly superior to his father in the attractiveness of his expository style, is, in regard to his economic doctrine, substantially at the same point of view. It is in their general philosophical conceptions and their views of social aims and ideals that the elder and younger Mill occupy quite different positions in the line of progress. The latter could not, for example, in his adult period have put forward a theory of government the shallow sophistries which the plain good sense of Macaulay sufficed to expose in the writings of the former; and he had a nobleness of feeling which, in relation to the higher social questions, raised him far above the ordinary coarse utilitarianism of the Benthamites.

The larger and more philosophic spirit in which Mill dealt with social subjects was undoubtedly in great measure due to the influence of Comte, to whom, as Mr. Bain justly says, he was under greater obligations than he himself was disposed to admit. Had he more completely undergone that influence, we are sometimes tempted to think he might have wrought the reform in economics which still remains to be achieved, emancipating the science from the *a priori* system, and founding a genuine theory of industrial life on observation in the broadest sense. But probably the time was not ripe for such a construction, and it is possible that Mill's native intellectual defects might have made him unfit for the task, for, as Roscher has said, "ein historischer Kopf war er nicht." However this might have been, the effects of his early training, in which positive were largely alloyed with metaphysical elements, sufficed in fact to prevent his attaining a perfectly normal mental attitude. He never altogether overcame the vicious direction which he had received from the teaching of his father, and the influence of the Benthamite group in which he was brought up.

Hence it was that, according to the striking expression of Roscher, his whole view of life was "zu wenig aus Einem Gusse." The incongruous mixture of the narrow dogmas of his youthful period with the larger ideas of a later stage gave a wavering and indeterminate character to his entire philosophy. He is, on every side, eminently "un-final"; he represents tendencies to new forms of opinion, and opens new vistas in various directions, but founds scarcely anything, and remains indeed, so far as his own position is concerned, not merely incomplete but incoherent. It is, however, precisely this dubious position which seems to us to give a special interest to his career, by fitting him in a peculiar degree to prepare and facilitate transitions.

What he himself thought to be "the chief merit of his treatise" was the marked distinction drawn between the theory of production and that of distribution, the laws of the former being based on unalterable natural facts, whilst the course of distribution is modified from time to time by the changing ordinances of society. This distinction, we may remark, must not be too absolutely stated, for the organization of production changes with social growth, and, as Lauderdale long ago showed, the nature of the distribution in a community reacts on production. But there is a substantial truth in the distinction, and the recognition of it tends to concentrate attention on the question—How can we improve the existing distribution of wealth? The study of this problem led Mill, as he advanced in years, further and further in the direction of socialism; and, whilst to the end of his life his book continued to deduce the Ricardian doctrines from the principle of enlightened selfishness, he was looking forward to an order of things in which synergy should be founded on sympathy.

The gradual modification of his views in relation to the economic constitution of society is set forth in his *Autobiography*. In his earlier days, he tells us, he "had seen little further than the *old school*" (note this significant title) "of political economy into the possibilities of fundamental improvement in social arrangements. Private property, as now understood, and inheritance appeared the *dernier mot* of legislation." The notion of proceeding to any radical redress of the injustice "involved in the fact that some are born to riches and the vast majority to poverty" he had then reckoned chimerical. But now his views were such as would "class him decidedly under the general designation of socialist"; he had come to believe that the whole contemporary framework of economic life was merely temporary and provisional, and that a time would come when "the division of the produce of labor, instead of depending, as in so great a degree it now does, on the accident of birth, would be made by concert on an acknowledged principle of justice." "The social problem of the future" he considered to be "how to unite the greatest individual liberty of action," which was often compromised in socialistic schemes, "with a common ownership in the raw material of the globe, and an equal participation in all the benefits of combined labor." These ideas were scarcely indicated in the first edition of the *Political Economy*, rather more clearly and fully in the second, and quite unequivocally in the third,—the French Revolution of 1848 having, as he says, made the public more open to the reception of novelties in opinion.

Whilst thus looking forward to a new economic order, he yet thinks its advent very remote, and believes that the inducements of private interest will in the meantime be indispensable. On the spiritual side he maintains a similar attitude of expectancy. He anticipates the ultimate disappearance of theism, and the substitution of a purely human religion, but believes that the existing doctrine will long be necessary as a stimulus and a control. He thus saps existing foundations without providing anything to take their place, and maintains the necessity of conserving for indefinite

periods what he has radically discredited. Nay, even whilst sowing the seeds of change in the direction of a socialistic organization of society, he favors present or proximate arrangements which would urge the industrial world towards other issues. The system of peasant proprietorship of land is distinctly individualistic in its whole tendency; yet he extravagantly praises it in the earlier part of his book, only receding from that laudation when he comes to the chapter on the future of the laboring classes. And the system of so-called co-operation in production which he so warmly commended in the later editions of his work, and led some of his followers to preach as the one thing needful, would inevitably strengthen the principle of personal property, and, whilst professing at most to substitute the competition of associations for that of individuals, would by no means exclude the latter.

The elevation of the working classes he bound up too exclusively with the Malthusian ethics, on which he laid quite an extravagant stress, though, as Mr. Bain has observed, it is not easy to make out his exact views, any more than his father's, on this subject. We have no reason to think that he ever changed his opinion as to the necessity of a restriction on population; yet that element seems foreign to the socialistic idea to which he increasingly leaned. It is at least difficult to see how, apart from individual responsibility for the support of a family, what Malthus called moral restraint could be enforced. This difficulty is indeed the fatal flaw which, in Malthus's own opinion, vitiated the scheme of Godwin.

Mill's openness to new ideas and his enthusiasm for improvement cannot be too much admired. But there appears to have been combined with these fine traits in his mental constitution a certain want of practical sense, a failure to recognize and acquiesce in the necessary conditions of human life, and a craving for "better bread than can be made of wheat." He entertained strangely exaggerated, or rather perverted, notions of the "subjection," the capacities, and the rights of women. He encourages a spirit of revolt on the part of working men against their perpetual condemnation, as a class, to the lot of living by wages, without giving satisfactory proof that this state of things is capable of change, and without showing that such a lot, duly regulated by law and morality, is inconsistent with their real happiness. He also insists on the "independence" of the working class—which according to him *farà da se*—in such a way as to obscure, if not to controvert, the truths that superior rank and wealth are naturally invested with social power, and are bound in duty to exercise it for the benefit of the community at large, and especially of its less favored members. And he attaches a quite undue importance to mechanical and, indeed, illusory expedients, such as the limitation of the power of bequest and the confiscation of the "unearned increment" of rent.

With respect to economic method also, he shifted his position; yet to the end occupied uncertain ground. In the fifth of his early essays he asserted that the method *a priori* is the only mode of investigation in the social sciences, and that the method *a posteriori* "is altogether inefficacious in those sciences, as a means of arriving at any considerable body of valuable truth." When he wrote his *Logic*, he had learned from Comte that the *a posteriori* method—in the form which he chose to call "inverse deduction"—was the only mode of arriving at truth in general sociology; and his admission of this at once renders the essay obsolete. But, unwilling to relinquish the *a priori* method of his youth, he tries to establish a distinction of two sorts of economic inquiry, one of which, though not the other, can be handled by that method. Sometimes he speaks of political economy as a department "carved out of the general body of the science of society;" whilst on the other hand the title of his systematic work implies a doubt whether political economy is a part of "social philosophy" at all, and not rather a

study preparatory and auxiliary to it. Thus, on the logical as well as the dogmatic side, he halts between two opinions. Notwithstanding his misgivings and even disclaimers, he yet remained, as to method, a member of the old school, and never passed into the new or "historical" school, to which the future belongs.

The question of economic method was also taken up by the ablest of his disciples, John Elliott Cairnes.

Cairnes (1824-75), who devoted a volume to the subject (*Logical Method of Political Economy*, 1857; 2d ed., 1875). Prof. Walker has lately spoken of the method advocated by Cairnes as different from that put forward by Mill, and has even represented the former as similar to, if not identical with, that of the German historical school. But this is certainly an error. Cairnes, notwithstanding some apparent vacillation of view and certain concessions more formal than real, maintains the utmost rigor of the deductive method; he distinctly affirms that in political economy there is no room for induction at all, "the economist starting with a knowledge of ultimate causes," and being thus, "at the outset of his enterprise, at the position which the physicist only attains after ages of laborious research." He does not, indeed, seem to be advanced beyond the point of view of Senior, who professed to deduce all economic truth from four elementary propositions. Whilst Mill in his *Logic* represents verification as an essential part of the process of demonstration of economic laws, Cairnes holds that, as they "are not assertions respecting the character or sequence of phenomena" (though what else can a scientific law be?), "they can neither be established nor refuted by statistical or documentary evidence." A proposition which affirms nothing respecting phenomena cannot be controlled by being confronted with phenomena. Notwithstanding the unquestionable ability of his book, it appears to mark, in some respects, a retrogression in methodology, and can for the future possess only an historical interest.

Regarded in that light, the labors of Mill and Cairnes on the method of the science, though intrinsically unsound, had an important negative effect. They let down the old political economy from its traditional position, and reduced its extravagant pretensions by two modifications of commonly accepted views. First, whilst Ricardo had never doubted that in all his reasonings he was dealing with human beings as they actually exist, they showed that the science must be regarded as a purely hypothetic one. Its deductions are based on unreal, or at least one-sided, assumptions, the most essential of which is that of the existence of the so-called "economic man," a being who is influenced by two motives only, that of acquiring wealth and that of avoiding exertion; and only so far as the premises framed on this conception correspond with fact can the conclusions be depended on in practice. Senior in vain protested against such a view of the science, which, as he saw, compromised its social efficacy; whilst Torrens, who had previously combated the doctrines of Ricardo, hailed Mill's new presentation of political economy as enabling him, whilst in one sense rejecting those doctrines, in another sense to accept them. Secondly, beside economic science, it had often been said, stands an economic art,—the former ascertaining truths respecting the laws of economic phenomena, the latter prescribing the right kind of economic action; and many had assumed that, the former being given, the latter is also in our possession—that, in fact, we have only to convert theorems into precepts, and the work is done. But Mill and Cairnes made it plain that this statement could not be accepted, that action can no more in the economic world than in any other province of life be regulated by considerations borrowed from that department of things only, that economics can suggest ideas which are to be kept in view, but that, standing alone, it cannot direct conduct—an office for which a wider prospect of human affairs is required. This matter is

best elucidated by a reference to Comte's classification, or rather hierarchical arrangement, of the sciences. Beginning with the least complex, mathematics, we rise successively to astronomy, physics, chemistry, thence to biology, and from it again to sociology. In the course of this ascent we come upon all the great laws which regulate the phenomena of the inorganic world, of organized beings, and of society. A further step, however, remains to be taken—namely, to morals; and at this point theory and practice tend to coincide, because every element of conduct has to be considered in relation to the general good. In the final synthesis all the previous analyses have to be used as instrumental, in order to determine how every real quality of things or men may be made to converge to the welfare of humanity.

Cairnes's most important economic publication was his last, entitled *Some Leading Principles of Political Economy, newly Expounded*, 1874. In this work, which does not profess to be a complete treatise on the science, he criticizes and emends the statements which preceding writers had given of some of its principal doctrines, and treats elaborately of the limitations with which they are to be understood, and the exceptions to them which may be produced by special circumstances. Whilst marked by great ability, it affords evidence of what has been justly observed as a weakness in Cairnes's mental constitution—his "deficiency in intellectual sympathy," and consequent frequent inability to see more than one side of a truth.

The three divisions of the book relate respectively to (1) value, (2) labor and capital, and (3) international trade. In the first he begins by elucidating the meaning of the word "value," and under this head controverts the view of Jevons that the exchange value of anything depends entirely on its utility, without, perhaps, distinctly apprehending what Jevons meant by this proposition. On supply and demand he shows, as Say had done before, that these, regarded as aggregates, are not independent, but strictly connected and mutually dependent phenomena—identical, indeed, under a system of barter, but, under a money system, conceivable as distinct. Supply and demand with respect to particular commodities must be understood to mean supply and demand at a given price; and thus we are introduced to the ideas of market price and normal price (as, following Cherbuliez, he terms what Smith less happily called natural price). Normal price again leads to the consideration of cost of production, and here, against Mill and others, he denies that profit and wages enter into cost of production; in other words, he asserts what Senior (whom he does not name) had said before him, though he had not consistently carried out the nomenclature, that cost of production is the sum of labor and abstinence necessary to production, wages and profits being the remuneration of sacrifice and not elements of it. But, it may well be asked, How can an amount of labor be added to an amount of abstinence? Must not wages and profits be taken as "measures of cost?" By adhering to the conception of "sacrifice," he exposes the emptiness of the assertion that "dear labor is the great obstacle to the extension of British trade"—a sentence in which "British trade" means capitalists' profits. At this point we are introduced to a doctrine now first elaborated, though there are indications of it in Mill, of whose theory of international values it is in fact an extension. In foreign trade cost of production, in Cairnes's sense, does not regulate values, because it cannot perform that function except under a régime of effective competition, and between different countries effective competition does not exist. But, Cairnes asks, to what extent does it exist in domestic industries? So far as capital is concerned, he thinks the condition is sufficiently fulfilled over the whole field—a position, let it be said in passing, which he does not seem to make out, if we consider the practical immobility of most invested, as distinct from disposable, capital. But in the case of labor the requisite competition takes place only within certain social, or rather industrial, strata. The world of industry may be divided into a series of superposed groups, and these groups are practically "non-competing," the disposable labor in any one of them being rarely capable of choosing its field in a higher. The law that cost of production determines price cannot, therefore, be absolutely stated, respecting domestic any more than respecting international exchange; as it fails for the latter universally, so it fails for the former as between non-competing groups. The law that holds between these is

similar to that governing international values, which may be called the equation of reciprocal demand. Such a state of relative prices will establish itself amongst the products of these groups as shall enable that portion of the products of each group which is applied to the purchase of the products of all other groups to discharge its liabilities towards those other groups. The reciprocal demand of the groups determines the "average relative level" of prices within each group; whilst cost of production regulates the distribution of price among the individual products of each group. This theorem is perhaps of no great practical value; but the tendency of the whole investigation is to attenuate the importance of cost of production as a regulator of normal price, and so to show that yet another of the accepted doctrines of the science had been propounded in too rigid and absolute a form. As to market price, the formula by which Mill had defined it as the price which equalizes demand and supply Cairnes shows to be an identical proposition, and he defines it as the price which most advantageously adjusts the existing supply to the existing demand pending the coming forward of fresh supplies from the sources of production.

His second part is chiefly remarkable for his defence of what is known as the wages fund doctrine, to which we adverted when speaking of Senior. Mill had given up this doctrine, having been convinced by Thornton that it was erroneous; but Cairnes refused to follow his leader, who, as he believes, ought not to have been convinced. After having given what is certainly a fallacious reply to Longe's criticism of the expression "average rate of wages," he proceeds to vindicate the doctrine in question by the consideration that the amount of a nation's wealth devoted at any time to the payment of wages—if the character of the national industries and the methods of production employed remain the same—is in a definite relation to the amount of its general capital; the latter being given, the former is also given. In illustrating his view of the subject, he insists on the principle (true in the main, but too absolutely formulated by Mill) that "demand for commodities is not demand for labor." It is not necessary here to follow his investigation, for his reasoning has not satisfied his successors, with the exception of Fawcett, and the question of wages is now commonly treated without reference to a supposed determinate wages fund. Cairnes next studies trades-unionism in relation to wages, and arrives in substance at the conclusion that the only way in which it can affect their rate is by accelerating an advance which must ultimately have taken place independently of its action. He also takes occasion to refute Mr. (now Sir Thomas) Brassey's supposed law of a uniform cost of labor in every part of the world. Turning to consider the material prospects of the working classes, he examines the question of the changes which may be expected in the amount and partition of the fund out of which abstinence and labor are remunerated. He here enunciates the principle (which had been, however, stated before him by Ricardo and Senior) that the increased productiveness of industry will not affect either profit or wages unless it cheapen the commodities which the laborer consumes. These latter being mostly commodities of which raw produce is the only or principal element, their cost of production, notwithstanding improvements in knowledge and art, will increase unless the numbers of the laboring class be steadily kept in check; and hence the possibility of elevating the condition of the laborer is confined within very narrow limits, if he continues to be a laborer only. The condition of any substantial and permanent improvement in his lot is that he should cease to be a mere laborer—that profits should be brought to reinforce the wages fund, which has a tendency to decline relatively to the general capital of a country. And hence Cairnes—abandoning the purely theoretic attitude which he elsewhere represents as the only proper one for the economist—recommends the system of so-called co-operation (that is, in fact, the abolition of the large capitalist) as offering to the working classes "the sole means of escape from a harsh and hopeless destiny," and puts aside rather contemptuously the opposition of the positivists to this solution, which yet many besides the positivists, as, for example, Leslie and F. A. Walker, regard as chimerical.

The third part is devoted mainly to an exposition of Ricardo's doctrine of the conditions of international trade and Mill's theory of international values. The former Cairnes modifies by introducing his idea of the partial influence of reciprocal demand, as distinguished from cost of production, on the regulation of domestic prices, and founds on this rectification an interesting account of the connection between the wages prevailing in a country and the character and course of its external trade. He emends Mill's statement, which represented the produce of a

country as exchanging for that of other countries at such values "as are required in order that the whole of her exports may exactly pay for the whole of her imports" by substituting for the latter phrase the condition that each country should by means of her exports discharge all of her foreign liabilities—in other words, by introducing the consideration of the balance of debts. This idea was not new; it had been indicated by J. L. Foster as early as 1804, and was touched on by Mill himself; but he expounds it well; and it is important as clearing away common misconceptions, and sometimes removing groundless alarms. Passing to the question of free trade, he disposes of some often-repeated protectionist arguments, and in particular refutes the American allegation of the inability of the highly-paid labor of that country to compete with the "pauper labor" of Europe. He is not so successful in meeting the "political argument," founded on the admitted importance for civilization of developing diversified national industries; and he meets only by one of the highly questionable commonplaces of the doctrinaire economists Mill's proposition that protection may foster nascent industries really adapted to a country till they have struck root and are able to endure the stress of foreign competition.

We have dwelt at some length on this work of Cairnes, not only because it presents the latest forms of several accepted economic doctrines, but also because it is, and, we believe, will remain, the last important product of the old English school. The author at the outset expresses the hope that it will strengthen and add consistency to the scientific fabric "built up by the labors of Adam Smith, Malthus, Ricardo, and Mill." Whilst recognizing with him the great merits of Smith, and the real abilities and services of his three successors here named, we cannot entertain the same opinion as Cairnes respecting the permanence of the fabric they constructed. We hold that a new edifice is required, incorporating indeed many of the materials of the old, but planned on different ideas and in some respects with a view to different ends—above all, resting on different philosophic foundations, and having relation in its whole design to the more comprehensive structure of which it will form but one department, namely, the general science of society.

We have already had occasion to refer to Cairnes's *Essays in Political Economy*, 1873. His *Slave Power* (1862) was the most valuable work which appeared on the subject of the great American conflict.

France.—All the later European schools presuppose—in part adopting, in part criticising—the work of the English economists from Smith¹ to Ricardo and the Epigoni. The German school has had in a greater degree than any other a movement of its own,—following, at least in its more recent period, an original method, and tending to special and characteristic conclusions. The French school, on the other hand,—if we omit the socialists, who do not here come under consideration,—has in the main reproduced the doctrines of the leading English thinkers,—stopping short, however, in general of the extremes of Ricardo and his disciples. In the field of exposition the French are unrivalled; and in political economy they have produced a series of more or less remarkable systematic treatises, text books, and compendiums, at the head of which stands the celebrated work of J. B. Say. But the number of seminal minds which have appeared in French economic literature—of writers who have contributed important truths, introduced improvements of method, or presented the phenomena under new lights—has not been large. Sismondi, Dunoyer, and Bastiat will deserve our attention, as being the most important of those who occupy independent positions (whether permanently tenable or not), if we pass over for the present the great philosophical renovation of Auguste Comte, which comprehended actually or potentially all the branches of sociological inquiry. Before estimating the labors of

¹ The first French translation of the *Wealth of Nations*, by Blavet, appeared in the *Journal de l'Agriculture, du Commerce, des Finances, et des Arts*, 1779–80; new editions of it were published in 1781, 1788, and 1800; it was also printed at Amsterdam in 1784. Smith himself recommended it in his third edition of the original as excellent. In 1790 appeared the translation by Roucher, with notes by Condorcet, and in 1802 that by Count Germain Garnier, executed during his exile in England, which is now considered the standard version, and has been reproduced, with notes by Say, Sismondi, Blanqui, etc., in the *Collection des Principaux Economistes*.

Bastiat, we shall find it desirable to examine the views of Carey, the most renowned of American economists, with which the latest teachings of the ingenious and eloquent Frenchmen are, up to a certain point, in remarkable agreement. Cournot, too, must find a place among the French writers of this period, as the chief representative of the conception of a mathematical method in political economy.

Of Jean Baptiste Say (1767-1832) Ricardo says—
Say.

"He was the first, or among the first, of Continental writers who justly appreciated and applied the principles of Smith, and has done more than all other Continental writers taken together to recommend that enlightened and beneficial system to the nations of Europe." The *Wealth of Nations* in the original language was placed in Say's hands by Clavière, afterwards minister, then director of the assurance society of which Say was a clerk; and the book made a most powerful impression on him. Long after, when Dupont de Nemours complained of his injustice to the physiocrats, and claimed him as, through Smith, a spiritual grandson of Quesnay and nephew of Turgot, he replied that he had learned to read in the writings of the mercantile school, had learned to think in those of Quesnay and his followers, but that it was in Smith that he had learned to seek the causes and the effects of social phenomena in the nature of things, and to arrive at this last by a scrupulous analysis. His *Traité d'Economie Politique* (1803) was essentially founded on Smith's work, but he aimed at arranging the materials in a more logical and instructive order. He has the French art of easy and lucid exposition, though his facility sometimes degenerates into superficiality; and hence his book became popular, both directly and through translations obtained a wide circulation, and diffused rapidly through the civilized world the doctrines of the master. Say's knowledge of common life, says Roscher, was equal to Smith's; but he falls far below him in living insight into larger political phenomena, and he carefully eschews historical and philosophical explanations. He is sometimes strangely shallow, as when he says that "the best tax is that smallest in amount." He appears not to have much claim to the position of an original thinker in political economy. Ricardo, indeed, speaks of him as having "enriched the science by several discussions, original, accurate, and profound." What he had specially in view in using these words was what is, perhaps rather pretentiously, called Say's *théorie des débouchés*, with his connected disproof of the possibility of a universal glut. The theory amounts simply to this, that buying is also selling, and that it is by producing that we are enabled to purchase the products of others. Several distinguished economists, especially Malthus and Sismondi, in consequence chiefly of a misinterpretation of the phenomena of commercial crises, maintained that there might be general over-supply or excess of all commodities above the demand. This Say rightly denied. A particular branch of production may, it must indeed be admitted, exceed the existing capabilities of the market; but, if we remember that supply is demand, that commodities are purchasing power, we cannot accept the doctrine of the possibility of a universal glut without holding that we can have too much of everything—that "all men can be so fully provided with the precise articles they desire as to afford no market for each other's superfluities." But, whatever services he may have rendered by original ideas on those or other subjects, his great merit is certainly that of a propagandist and popularizer.

The imperial police would not permit a second edition of his work to be issued without the introduction of changes which, with noble independence, he refused to make; and that edition did not therefore appear till 1814. Three other editions were published during the life of the author—in 1817, 1819 and 1826. In 1828

Say published a second treatise, *Cours complet d'Economie Politique Pratique*, which contained the substance of his lectures at the Conservatoire des Arts et Métiers and at the Collège de France. Whilst in his earlier treatise he had kept within the narrow limits of strict economics, in his later work he enlarged the sphere of discussion, introducing in particular many considerations respecting the economic influence of social institutions.

Jean Charles L. Simonde de Sismondi (1773-1842), author of the *Histoire des Républiques Sismondi. Italiennes du moyen âge*, represents in the economic field a protest, founded mainly on humanitarian sentiment, against the dominant doctrines. He wrote first a treatise *De la Richesse Commerciale* (1803), in which he followed strictly the principles of Adam Smith. But he afterwards came to regard these principles as insufficient and requiring modification. He contributed an article on political economy to the *Edinburgh Encyclopædia*, in which his new views were partially indicated. They were fully developed in his principal economic work, *Nouveaux Principes d'Economie Politique, ou de la Richesse dans ses rapports avec la Population* (1819; 2d ed., 1827). This work, as he tells us, was not received with favor by economists, a fact which he explains by the consideration that he had "attacked an orthodoxy—an enterprise dangerous in philosophy as in religion." According to his view, the science, as commonly understood, was too much of a mere chrematistic: it studied too exclusively the means of increasing wealth, and not sufficiently the use of this wealth for producing general happiness. The practical system founded on it tended, as he believed, not only to make the rich richer, but to make the poor poorer and more dependent; and he desired to fix attention on the question of distribution as by far the most important, especially in the social circumstances of recent times.

The personal union in Sismondi of three nationalities, the Italian, the French and the Swiss, and his comprehensive historical studies, gave him a special largeness of view; and he was filled with a noble sympathy for the suffering members of society. He stands nearer to socialism than any other French economist proper, but it is only in sentiment, not in opinion, that he approximates to it; he does not recommend any socialistic scheme. On the contrary, he declares in a memorable passage that, whilst he sees where justice lies, he must confess himself unable to suggest the means of realizing it in practice; the division of the fruits of industry between those who are united in their production appears to him vicious; but it is, in his judgment, almost beyond human power to conceive any system of property absolutely different from that which is known to us by experience. He goes no further than protesting, in view of the great evils which he saw around him, against the doctrine of *laissez faire*, and invoking, somewhat vaguely, the intervention of Governments to "regulate the progress of wealth" and to protect the weaker members of the community.

His frank confession of impotence, far wiser and more honorable than the suggestion of precipitate and dangerous remedies, or of a recurrence to outworn mediæval institutions, has not affected the reputation of the work. A prejudice was indeed early created against it in consequence of its partial harmony of tone, though, as we have seen, not of policy, with socialism, which was then beginning to show its strength, as well as by the rude way in which his description of the modern industrial system, especially as it existed in England, disturbed the complacent optimism of some members of the so-called orthodox school. These treated the book with ill-disguised contempt, and Bastiat spoke of it as preaching an *économie politique à rebours*. But it has held its place in the literature of the science, and is now even more interesting than when it first appeared, because in our time there is a more general disposition, instead of denying or glossing over the serious evils of industrial society, to face and remove or at least mitigate them. The *laissez faire* doctrine, too, has been discredited

in theory and abandoned in practice; and we are ready to admit Sismondi's view of the state as a power not merely intrusted with the maintenance of peace, but charged also with the mission of extending the benefits of the social union and of modern progress as widely as possible through all classes of the community. Yet the impression which his treatise leaves behind it is a discouraging one; and this because he regards as essentially evil many things which seem to be the necessary results of the development of industry. The growth of a wealthy capitalist class and of manufacture on the great scale, the rise of a vast body of workers who live by their labor alone, the extended application of machines, large landed properties cultivated with the aid of the most advanced appliances—all these he dislikes and deprecates; but they appear to be inevitable. The problem is how to regulate and moralize the system they imply; but we must surely accept it in principle, unless we aim at a thorough social revolution. Sismondi may be regarded as the precursor of the German economists known under the inexact designation of "Socialists of the Chair"; but their writings are much more hopeful and inspiring.

To the subject of population he devotes special care, as of great importance for the welfare of the working classes. So far as agriculturists are concerned, he thinks the system of what he calls patriarchal exploitation, where the cultivator is also proprietor, and is aided by his family in tilling the land—a law of equal division among the natural heirs being apparently presupposed—the one which is most efficacious in preventing an undue increase of the population. The father is, in such a case, able distinctly to estimate the resources available for his children, and to determine the stage of subdivision which would necessitate the descent of the family from the material and social position it had previously occupied. When children beyond this limit are born, they do not marry, or they choose amongst their number one to continue the race. This is the view which, adopted by J. S. Mill, makes so great a figure in the too favorable presentation by that writer of the system of peasant proprietors.

In no French economic writer is greater force or general solidity of thought to be found than Dunoyer. In Charles Dunoyer (1786–1862), author of *La Liberté du Travail* (1845; the substance of the first volume had appeared under a different title in 1825), honorably known for his integrity and independence under the régime of the Restoration. What makes him of special importance in the history of the science is his view of its philosophical constitution and method. With respect to method, he strikes the keynote at the very outset in the words "*rechercher expérimentalement*," and in professing to build on "*les données de l'observation et de l'expérience*." He shows a marked tendency to widen economics into a general science of society, expressly describing political economy as having for its province the whole order of things which results from the exercise and development of the social forces. This larger study is indeed better named sociology; and economic studies are better regarded as forming one department of it. But the essential circumstance is that, in Dunoyer's treatment of his great subject, the widest intellectual, moral, and political considerations are inseparably combined with purely economic ideas. It must not be supposed that by liberty, in the title of his work, is meant merely freedom from legal restraint or administrative interference; he uses it to express all that tends to give increased efficiency to labor. He is thus led to discuss all the causes of human progress, and to exhibit them in their historical working.

Treating, in the first part, of the influence of external conditions, of race, and of culture on liberty in this wider sense, he proceeds to divide all productive effort into two great classes, according as the action is exercised on things or on men, and censures the economists for having restricted their attention to the former. He studies in his second and third parts respectively the conditions of the efficiency of these two forms of human exertion. In treating of economic life, strictly so-called, he introduces his fourfold division of material industry, in part adopted by J. S. Mill, as "(1) extractive, (2) *voiturière*, (3) *manufacturière*, (4) *agricole*," a division which is useful for physical economics, but will always, when the larger social aspect of things is considered, be inferior to the more commonly accepted one

into agricultural, manufacturing, and commercial industry, banking being supposed as common president and regulator. Dunoyer, having in view only action on material objects, relegates banking, as well as commerce proper, to the separate head of exchange, which, along with association and gratuitous transmission (whether *inter vivos* or *mortis causa*), he classes apart as being, not industries, in the same sense with the occupations named, but yet functions essential to the social economy. The industries which act on man he divides according as they occupy themselves with (1) the amelioration of our physical nature, (2) the culture of our imagination and sentiments, (3) the education of our intelligence, and (4) the improvement of our moral habits; and he proceeds accordingly to study the social offices of the physician, the artist, the educator, and the priest. We meet in Dunoyer the ideas afterwards emphasized by Bastiat that the real subjects of human exchange are services; that all value is due to human activity; that the powers of nature always render a gratuitous assistance to the labor of man; and that the rent of land is really a form of interest on invested capital. Though he had disclaimed the task of a practical adviser in the often-quoted sentence—"Je n'impose rien; je ne propose même rien; j'expose," he finds himself, like all economists, unable to abstain from offering counsel. And his policy is opposed to any state interference with industry. Indeed he preaches in its extreme rigor the *laissez faire* doctrine, which he maintains principally on the ground that the spontaneous efforts of the individual for the improvement of his condition, by developing foresight, energy, and perseverance, are the most efficient means of social culture. But he certainly goes too far when he represents the action of Governments as normally always repressive and never directive. He was doubtless led into this exaggeration by his opposition to the artificial organizations of labor proposed by so many of his contemporaries, against which he had to vindicate the principle of competition, but his criticism of these schemes took, as Comte remarks, too absolute a character, tending to the perpetual interdiction of a true systematization of industry.

At this point it will be convenient to turn aside and notice the doctrines of the American economist Carey. Not much had been done before him in the science by citizens of the United States. Benjamin Franklin, otherwise of world-wide renown, was author of a number of tracts, in most of which he merely enforces practical lessons of industry and thrift, but in some throws out interesting theoretic ideas. Thus, fifty years before Smith, he suggested (as Petty, however, had already done) human labor as the true measure of value (*Modest Inquiry into the Nature and Necessity of a Paper Currency*, (1721), and in his *Observations concerning the Increase of Mankind* (1751) he expresses views akin to those of Malthus. Alexander Hamilton, secretary of the treasury, in 1791 presented in his official capacity to the House of Representatives of the United States a report on the measures by which home manufactures could be promoted. In this document he gives a critical account of the theory of the subject, represents Smith's system of free trade as possible in practice only if adopted by all nations simultaneously, ascribes to manufactures a greater productiveness than to agriculture, and seeks to refute the objections against the development of the former in America founded on the want of capital, the high rate of wages, and the low price of land. The conclusion at which he arrives is that for the creation of American manufactures a system of moderate protective duties was necessary, and he proceeds to describe the particular features of such a system. There is some reason to believe that the German economist List, of whom we shall speak hereafter, was influenced by Hamilton's work, having, during his exile from his native country, resided in the same State, Pennsylvania, of which Hamilton was a citizen.¹

Henry Charles Carey (1793–1879), son of an American citizen who had emigrated from Ireland, represents a reaction against the dispiriting character which the Smithian doctrines had assumed

mists.

Franklin.

Hamilton.

Carey.

¹ [Hamilton was a citizen of New York.—AM. ED.]

in the hands of Malthus and Ricardo. His aim was, whilst adhering to the individualistic economy, to place it on a higher and surer basis, and fortify it against the assaults of socialism, to which some of the Ricardian tenets had exposed it. The most comprehensive as well as mature exposition of his views is contained in his *Principles of Social Science* (1859). Inspired with the optimistic sentiment natural to a young and rising nation with abundant undeveloped resources and an unbounded outlook towards the future, he seeks to show that there exists, independently of human wills, a natural system of economic laws, which is essentially beneficent, and of which the increasing prosperity of the whole community, and especially of the working classes, is the spontaneous result,—capable of being defeated only by the ignorance or perversity of man resisting or impeding its action. He rejects the Malthusian doctrine of population, maintaining that numbers regulate themselves sufficiently in every well governed society, and that their pressure on subsistence characterizes the lower, not the more advanced, stages of civilization. He rightly denies the universal truth, for all stages of cultivation, of the law of diminishing returns from land. His fundamental theoretic position relates to the antithesis of wealth and value.

Wealth had been by most economists confounded with the sum of exchange values; even Smith, though at first distinguishing them, afterwards allowed himself to fall into this error. Ricardo had, indeed, pointed out the difference, but only near the end of his treatise, in the body of which value alone is considered. The later English economists had tended to regard their studies as conversant only with exchange; so far had this proceeded that Whately had proposed for the science the name of *Catallactics*. When wealth is considered as what it really is, the sum of useful products, we see that it has its origin in external nature as supplying both materials and physical forces, and in human labor as appropriating and adapting those natural materials and forces. Nature gives her assistance gratuitously; labor is the sole foundation of value. The less we can appropriate and employ natural forces in any production the higher the value of the product, but the less the addition to our wealth in proportion to the labor expended. Wealth, in its true sense of the sum of useful things, is the measure of the power we have acquired over nature, whilst the value of an object expresses the resistance of nature which labor has to overcome in order to produce the object. Wealth steadily increases in the course of social progress; the exchange-value of objects, on the other hand, decreases. Human intellect and faculty of social combination secure increased command over natural powers, and use them more largely in production, whilst less labor is spent in achieving each result, and the value of the product accordingly falls. The value of the article is not fixed by its cost of production in the past; what really determines it is the cost which is necessary for its reproduction under the present conditions of knowledge and skill. The dependence of value on cost, so interpreted, Carey holds to be universally true; whilst Ricardo maintained it only with respect to objects capable of indefinite multiplication, and in particular did not regard it as applicable to the case of land. Ricardo saw in the productive powers of land a free gift of nature which had been monopolized by a certain number of persons, and which became, with the increased demand for food, a larger and larger value in the hands of its possessors. To this value, however, as not being the result of labor, the owner had no rightful claim; he could not justly demand a payment for what was done by the "original and indestructible powers of the soil." But Carey held that land, as we are concerned with it in industrial life, is really an instrument of production which has been formed as such by man, and that its value is due to the labor expended on it in the past,—though measured, not by the sum of that labor, but by the labor necessary under existing conditions to bring new land to the same stage of productiveness. He studies the occupation and reclamation of land with peculiar advantage as an American, for whom the traditions of first settlement are living and fresh, and before whose eyes the process is indeed still going on. The difficulties of adapting a primitive soil to the work of yielding organic products for man's use can be lightly estimated only by an inhabitant of a country long under cultivation. It is, in Carey's view, the overcoming of these difficulties by arduous and continued effort that entitles the first occupier of land to his property in the soil. Its present value forms a very small proportion of the cost expended on it, because it rep-

resents only what would be required, with the science and appliances of our time, to bring the land from its primitive into its present state. Property in land is therefore only a form of invested capital—a quantity of labor or the fruits of labor permanently incorporated with the soil; for which, like any other capitalist, the owner is compensated by a share of the produce. He is not rewarded for what is done by the powers of nature, and society is in no sense defrauded by his sole possession. The so-called Ricardian theory of rent is a speculative fancy, contradicted by all experience. Cultivation does not in fact, as that theory supposes, begin with the best, and move downwards to the poorer soils in the order of their inferiority.¹ The light and dry higher lands are first cultivated; and only when population has become dense and capital has accumulated, are the low-lying lands, with their greater fertility, but also with their morasses, inundations, and miasmas, attacked and brought into occupation. Rent, regarded as a proportion of the produce, sinks, like all interest on capital, in process of time, but, as an absolute amount, increases. The share of the laborer increases, both as a proportion and an absolute amount. And thus the interests of these different social classes are in harmony.

But, Carey proceeds to say, in order that this harmonious progress may be realized, what is taken from the land must be given back to it. All the articles derived from it are really separated parts of it, which must be restored on pain of its exhaustion. Hence the producer and the consumer must be close to each other; the products must not be exported to a foreign country in exchange for its manufactures, and thus go to enrich as manure a foreign soil. In immediate exchange-value the landowner may gain by such exportation, but the productive powers of the land will suffer. And thus Carey, who had set out as an earnest advocate of free trade, arrives at the doctrine of protection: the "co-ordinating power" in society must intervene to prevent private advantage from working public mischief.² He attributes his conversion on this question to his observation of the effects of liberal and protective tariffs respectively on American prosperity. This observation, he says, threw him back on theory, and led him to see that the intervention referred to might be necessary to remove (as he phrases it) the obstacles to the progress of younger communities created by the action of older and wealthier nations. But it seems probable that the influence of List's writings, added to his own deep-rooted and hereditary jealousy and dislike of English predominance, had something to do with his change of attitude.

The practical conclusion at which he thus arrived, though it is by no means in contradiction to the doctrine of the existence of natural economic laws, accords but ill with his optimistic scheme; and another economist, accepting his fundamental ideas, applied himself to remove the foreign accretion, as he regarded it, and to preach the theory of spontaneous social harmonies in relation with the practice of free trade as its legitimate outcome.

Frédéric Bastiat (1801–1850), though not a profound thinker, was a brilliant and popular writer on economic questions. Though he always Bastiat. had an inclination for such studies, he was first impelled to the active propagation of his views by his earnest sympathy with the English anti-corn-law agitation. Naturally of an ardent temperament, he threw himself with zeal into the free-trade controversy, through which he hoped to influence French economic policy, and published in 1845 a history of the struggle under the title of *Cobden et la Ligue*. In 1845–48 appeared his *Sophismes Économiques* (Eng. trans. by P. J. Stirling, 1873), in which he exhibited his best qualities of mind. Though Cairnes goes too far in comparing this work with the *Lettres Provinciales*, it is certainly marked by much liveliness, point, and vigor. But to expose the absurdities of the ordinary protectionism was no difficult task; it is only in such a form as the doctrine assumed in the hands of List, as a purely provisional and preparatory scheme, that it deserves and demands

¹ It is, however, a mistake to suppose that the assumption of this historical order of descent is essential to the theory in question.

² This argument seems scarcely met by Prof. F. A. Walker, *Political Economy*, 50–52. But perhaps he is right in thinking that Carey exaggerates the importance of the considerations on which it is founded. Mill and Leslie remark that the transportation of agricultural products from the western to the Atlantic States has the same effect as their export to Europe, so far as this so-called "land-butcher" is concerned; besides, some manures are obtainable from abroad.

consideration. After the revolution of 1848, which for a time put an end to the free-trade movement in France, the efforts of Bastiat were directed against the socialists. Besides several minor pieces possessing the same sort of merit as the *Sophismes*, he produced, with a view to this controversy, his most ambitious as well as characteristic work, the *Harmonies Economiques* (Eng. trans. by P. J. Stirling, 1860). Only the first volume was published; it appeared in 1850, and its author died in the same year. Since then the notes and sketches which he had prepared as materials towards the production of the second volume have been given to the public in the collected edition of his writings (by Paillolet, with Life by Fontenay, 7 vols.), and we can thus gather what would have been the spirit and substance of the later portions of the book.

It will always be historically interesting as the last incarnation of thorough-going economic optimism. This optimism, recurring to its first origin, sets out from theological considerations, and Bastiat is commended by his English translator for treating political economy "in connection with final causes." The spirit of the work is to represent "all principles, all motives, all springs of action, all interests, as co-operating towards a grand final result which humanity will never reach, but to which it will always increasingly tend, namely, the indefinite approximation of all classes towards a level, which steadily rises,—in other words, the equalization of individuals in the general amelioration."

What claimed to be novel and peculiar in his scheme was principally his theory of value. Insisting on the idea that value does not denote anything inherent in the objects to which it is attributed, he endeavored to show that it never signifies anything but the ratio of two "services." This view he develops with great variety and felicity of illustration. Only the mutual services of human beings, according to him, possess value and can claim a retribution; the assistance given by nature to the work of production is always purely gratuitous, and never enters into price. Economic progress, as, for example, the improvement and larger use of machinery, tends perpetually to transfer more and more of the elements of utility from the domain of property, and therefore of value, into that of community, or of universal and unpurchased enjoyment. It will be observed that this theory is substantially identical with Carey's, which had been earlier propounded; and the latter author in so many words alleges it to have been taken from him without acknowledgment. It has not perhaps been sufficiently attended to that very similar views are found in Dunoyer, of whose work Bastiat spoke as exercising a powerful influence on "the restoration of the science," and whom Fontenay, the biographer of Bastiat, tells us he recognized as one of his masters, Charles Comte being the other.

The mode which has just been explained of conceiving industrial action and industrial progress is interesting and instructive so far as it is really applicable, but it was unduly generalized. Cairnes has well pointed out that Bastiat's theoretic soundness was injuriously affected by his habit of studying doctrines with a direct view to contemporary social and political controversies. He was thus predisposed to accept views which appeared to lend a sanction to legitimate and valuable institutions, and to reject those which seemed to him to lead to dangerous consequences. His constant aim is, as he himself expressed it, to "break the weapons" of antisocial reasoners "in their hands," and this preoccupation interferes with the single-minded effort towards the attainment of scientific truth. The creation or adoption of his theory of value was inspired by the wish to meet the socialistic criticism of property in land; for the exigencies of this controversy it was desirable to be able to show that nothing is ever paid for except personal effort. His view of rent was, therefore, so to speak, foreordained, though it may have been suggested, as indeed the editor of his posthumous fragments admits, by the writings of Carey. He held, with the American writer, that rent is purely the reward of the pains and expenditure of the landlord or his predecessors in the process of converting the natural

soil into a *farm* by clearing, draining, fencing, and the other species of permanent improvements.¹ He thus gets rid of (the so-called) Ricardian doctrine, which was accepted by the socialists, and by them used for the purpose of assailing the institution of landed property, or, at least, of supporting a claim of compensation to the community for the appropriation of the land by the concession of the "right to labor." As Cairnes has said, "what Bastiat did was this: having been at infinite pains to exclude gratuitous gifts of nature from the possible elements of value, and pointedly identified [rather, associated] the phenomena with 'human effort' as its exclusive source, he designates human effort by the term 'service,' and then employs this term to admit as sources of value those very gratuitous natural gifts the exclusion of which in this capacity constituted the essence of his doctrine." The justice of this criticism will be apparent to any one who considers the way in which Bastiat treats the question of the value of a diamond. That what is paid for in most cases of human dealings is *effort* no one can dispute. But it is surely a *reductio ad absurdum* of his theory of value, regarded as a doctrine of universal application, to represent the price of a diamond which has been accidentally found as remuneration for the effort of the finder in appropriating and transmitting it. And, with respect to land, whilst a large part of rent, in the popular sense, must be explained as interest on capital, it is plain that the native powers of the soil are capable of appropriation, and that then a price can be demanded and will be paid for their use.

Bastiat is weak on the philosophical side; he is filled with the ideas of theological teleology, and is led by these ideas to form *a priori* opinions of what existing facts and laws must necessarily be. And the *jus naturæ*, which, like metaphysical ideas generally, has its root in theology, is as much a postulate with him as with the physiocrats. Thus, in his essay on *Free Trade*, he says: "Exchange is a natural right like property. Every citizen who has created or acquired a product ought to have the option of either applying it immediately to his own use or ceding it to whosoever on the surface of the globe consents to give him in exchange the object of his desires." Something of the same sort had been said by Turgot; and in his time this way of regarding things was excusable, and even provisionally useful; but in the middle of the 19th century it was time that it should be seen through and abandoned.

Bastiat had a real enthusiasm for a science which he thought destined to render great services to mankind, and he seems to have believed intensely the doctrines which gave a special color to his teaching. If his optimistic exaggerations favored the propertied classes, they certainly were not prompted by self-interest or servility. But they *are* exaggerations; and, amidst the modern conflicts of capital and labor, his perpetual assertion of social harmonies is the cry of peace, peace, where there is no peace. The freedom of industry, which he treated as a sort of panacea, has undoubtedly brought with it great benefits; but a sufficient experience has shown that it is inadequate to solve the social problem. How can the advocates of economic revolution be met by assuring them that everything in the natural economy is harmonious—that, in fact, all they seek for already exists? A certain degree of spontaneous harmony does indeed exist, for society could not continue without it, but it is imperfect and precarious; the question is, How can we give to it the maximum of completeness and stability?

Augustin Cournot (1801-1877) appears to have been the first (the German, H. H. Gossen, Cournot, praised by Jevons, wrote in 1854) who, with a competent knowledge of both subjects, endeavored to apply mathematics to the treatment of economic questions. His treatise entitled *Recherches sur les Principes Mathématiques de la Théorie des Richesses* was published in 1838. He mentions in it only one previous enterprise of the same kind (though

¹ M. Leroy-Beaulieu has recently maintained (*Essai sur la Répartition des Richesses*, 2d ed., 1882) that this, though not strictly, is approximately true—that economic forms a very small part of actual rent.

there had in fact been others)—that, namely, of Nicolas François Canard, whose book, published in 1802, was crowned by the Institute, though “its principles were radically false as well as erroneously applied.” Notwithstanding Cournot’s just reputation as a writer on mathematics, the *Recherches* made little impression. The truth seems to be that his results are in some cases of little importance, in others of questionable correctness, and that, in the abstractions to which he has recourse in order to facilitate his calculations, an essential part of the real conditions of the problem is sometimes omitted. His pages abound in symbols representing unknown functions, the form of the function being left to be ascertained by observation of facts, which he does not regard as a part of his task, or only some known properties of the undetermined function being used as bases for deduction. Jevons includes in his list of works in which a mathematical treatment of economics, is adopted a second treatise which Cournot published in 1863, with the title *Principes de la Théorie des Richesses*. But in reality in the work so named, which is written with great ability, and contains much forcible reasoning in opposition to the exaggerations of economic optimists, the mathematical method is abandoned, and there is not an algebraical formula in the book. The author admits that the public has always shown a repugnance to the use of mathematical symbols in economic discussion, and, though he thinks they might be of service in facilitating exposition, fixing the ideas, and suggesting further developments, he acknowledges that a grave danger attends their use. The danger, according to him, consists in the probability that an undue value may be attached to the abstract hypotheses from which the investigator sets out, and which enable him to construct his formulæ. And his practical conclusion is that mathematical processes should be employed only with great precaution, or even not employed at all if the public judgment is against them, for “this judgment,” he says, “has its secret reasons, almost always more sure than those which determine the opinions of individuals.” It is an obvious consideration that the acceptance of unsound or one-sided abstract principles as the premises of argument does not depend on the use of mathematical forms, though it is possible that the employment of the latter may by association produce an illusion in favor of the certainty of those premises. But the great objection to the use of mathematics in economic reasoning is that it is necessarily sterile. If we examine the attempts which have been made to employ it, we shall find that the fundamental conceptions on which the deductions are made to rest are vague, indeed metaphysical, in their character. Units of animal or moral satisfaction, of utility, and the like are as foreign to positive science as a unit of dormitive faculty would be; and a unit of value, unless we understand by value the quantity of one commodity exchangeable under given conditions for another, is an equally indefinite idea. Mathematics can indeed formulate ratios of exchange when they have once been observed; but it cannot by any process of its own determine those ratios, for quantitative conclusions imply quantitative premises, and these are wanting. There is then no future for this kind of study, and it is only waste of intellectual power to pursue it. But the importance of mathematics as an educational introduction to all the higher orders of research is not affected by this conclusion. The study of the physical medium, or environment, in which economic phenomena take place, and by which they are affected, requires mathematics as an instrument; and nothing can ever dispense with the didactic efficacy of that science, as supplying the primordial type of rational investigation, giving the lively sentiment of decisive proof, and disinclining the mind to illusory conceptions and sophistical combinations. And a knowledge of at

least the fundamental principles of mathematics is necessary to economists to keep them right in their statements of doctrine, and prevent their enunciating propositions which have no definite meaning. Even distinguished writers sometimes betray a serious deficiency in this respect; thus they assert that one quantity “varies inversely as” another when what is meant is that the sum (not the product) of the two is constant; and they treat as capable of numerical estimation the amount of an aggregate of elements which, differing in kind, cannot be reduced to a common standard. As an example of the latter error, it may be mentioned that “quantity of labor,” so often spoken of by Ricardo, and in fact made the basis of his system, includes such various species of exertion as will not admit of summation or comparison.

Italy.—The first Italian translation of the *Wealth of Nations* appeared in 1780. The most distinguished Italian economist of the period here dealt with was, however, no disciple of Smith. This was Melchiorre Gioja, author, besides statistical and other writings, of a voluminous work entitled *Nuovo Prospetto delle Scienze Economiche* (6 vols., 1815–17; the work was never completed), intended to be an encyclopædia of all that had been taught by theorists, enacted by Governments, or effected by populations in the field of public and private economy. It is a learned and able treatise, but so overlaid with quotations and tables as to repel rather than attract readers. Gioja admired the practical economic system of England, and enlarges on the advantages of territorial properties, manufactures, and mercantile enterprises on the large as opposed to the small scale. He defends a restrictive policy, and insists on the necessity of the action of the state as a guiding, supervising, and regulating power in the industrial world. But he is in full sympathy with the sentiment of his age against ecclesiastical domination and other mediæval survivals. We can but very briefly notice Romagnosi (d. 1835), who, by his contributions to periodical literature, and by his personal teaching, greatly influenced the course of economic thought in Italy; Antonio Scialoja (*Principii d'Economia Sociale*, 1840; and *Carestia e Governo*, 1853), an able advocate of free trade (d. 1877); Luigi Cibrario, well known as the author of *Economia Politica del medio evo* (1839; 5th ed. 1861; French trans. by Barneaud, 1859), which is in fact a view of the whole social system of that period; Girolamo Boccardo (b. 1829; *Trattato Teorico-pratico di Economia politica*, 1853); the brilliant controversialist Francesco Ferrara, professor at Turin from 1849 to 1858 (in whose school most of the present Italian teachers of the science were, directly or indirectly, educated), a partisan of the *laissez faire* doctrine in its most extreme form, and an advocate of the peculiar opinions of Carey and Bastiat on the subject of rent; and, lastly, the Neapolitan minister Ludovico Bianchini (*Principii della Scienza del Ben Vivere Sociale*, 1845 and 1855), who is remarkable as having followed in some degree an historical direction, and asserted the principle of relativity, and who also dwelt on the relations of economics with morals, by a due attention to which the Italian economists have, indeed, in general been honorably distinguished.

Spain.—The *Wealth of Nations* was translated into Spanish by Ortiz in 1794. It may Jovellanos, perhaps have influenced Gaspar de Jovellanos, who in 1795 presented to the council of Castile and printed in the same year his celebrated *Informe de la Sociedad Economica de Madrid en expediente de Ley Agraria*, which was a powerful plea for reform, especially in taxation and the laws affecting agriculture, including those relating to the systems of entail and mortmain. An English version of this memoir is given in the translation (1809) of Laborde’s *Spain*, vol. iv.

Germany.—Roscher observes that Smith did not at

first produce much impression in Germany.¹ He does not appear to have been known to Frederick the Great; he certainly exercised no influence on him. Nor did Joseph II. take notice of his work. And of the minor German princes, Karl Friedrich of Baden, as a physiocrat, would not be accessible to his doctrines. It was otherwise in the generation whose principal activity belongs to the first decade of the 19th century. The Prussian statesmen who were grouped round Stein had been formed as economists by Smith, as had also Gentz, intellectually the most important man of the Metternich régime in Austria.

The first German expositors of Smith who did more than merely reproduce his opinions were Christian Jacob Kraus (1753-1807), George Sartorius (1766-1828), and August Ferdinand Lüder (1760-1819). They contributed independent views from different standpoints,—the first from that of the effect of Smith's doctrine on practical government, the second from that of its bearing on history, the third from that of its relation to statistics. Somewhat later came Gottlieb Hufeland (1760-1817), Johann Friedrich Eusebius Lotz (1771-1838), and Ludwig Heinrich von Jakob (1759-1827), who, whilst essentially of the school of Smith, apply themselves to a revision of the fundamental conceptions of the science. These authors did not exert anything like the wide influence of Say, partly on account of the less attractive form of their writings, but chiefly because Germany had not then, like France, a European audience. Julius von Soden (1754-1831) is largely founded on Smith, whom, however, he criticises with undue severity, especially in regard to his form and arrangement; the *Wealth of Nations* he describes as a series of precious fragments, and censures Smith for the absence of a comprehensive view of his whole subject, and also as one-sidedly English in his tendencies.

The highest form of the Smithian doctrine in Germany is represented by four distinguished names: Karl Heinrich Rau (1792-1870), Friedrich Nebenius (1784-1857), Friedrich Benedict Wilhelm Hermann (1795-1868), and Johann Heinrich von Thünen (1783-1850).

Rau's characteristic is "erudite thoroughness." His *Lehrbuch* (1826-32) is an encyclopædia of all that up to his time had appeared in Germany under the several heads of *Volkswirtschaftslehre*, *Volkswirtschaftspolitik*, and *Finanzwissenschaft*. His book is rich in statistical observations, and is particularly instructive on the economic effects of different geographical conditions. It is well adapted for the teaching of public servants whose duties are connected with economics, and it has in fact been the source from which the German official world down to the present time has derived its knowledge of the science. In his earlier period Rau had insisted on the necessity of a reform of economic doctrine (*Ansichten der Volkswirtschaft*, 1821), and had tended towards relativity and the historical method; but he afterwards conceived the mistaken notion that that method "only looked into the past without studying the means of improving the present," and became himself purely practical in the narrower sense of that word. He has the merit of having given a separate treatment of *Unternehmergewinn*, or wages of management. The Prussian minister Nebenius, who was largely instrumental in the foundation of the Zollverein, was author of a highly esteemed monograph on public credit (1820). The *Staatswirtschaftliche Untersuchungen* (1832; 2d ed., 1870) of Hermann do not form a regular system, but treat a series of important special subjects.

Hermann. His rare technological knowledge gave him a great advantage in dealing with some economic questions. He reviewed the principal fundamental ideas of the science with great thoroughness and acuteness. "His strength," says Roscher, "lies in his clear, sharp, exhaustive distinction between the several elements of a complex conception, or the several steps comprehended in a complex act." For keen analytical power his German brethren compare him with Ricardo. But he avoids several one-sided views of the English economist. Thus he places public spirit beside egoism as an economic motor, regards price as not measured by labor only but as a product of several factors, and habitually contemplates the consump-

tion of the laborer, not as a part of the cost of production to the capitalist but as the main practical end of economics. Von Thünen is known principally by his remarkable work entitled *Der Isolierte Staat in Beziehung auf Landwirtschaft und Nationalökonomie* (1826; 2d ed., 1842). In this treatise, which is a classic in the political economy of agriculture, there is a rare union of exact observation with creative imagination. With a view to exhibit the natural development of agriculture, he imagines a state, isolated from the rest of the world, circular in form and of uniform fertility, without navigable rivers or canals, with a single large city at its centre, which supplies it with manufactures and receives in exchange for them its food products, and proceeds to study the effect of distance from this central market on the agricultural economy of the several concentric spaces which compose the territory. The method, it will be seen, is highly abstract, but, though it may not be fruitful, it is quite legitimate. The author is under no illusion blinding him to the unreality of the hypothetical case. The supposition is necessary, in his view, in order to separate and consider apart one essential condition—that, namely, of situation with respect to the market. It was his intention (imperfectly realized, however) to institute afterwards several different hypotheses in relation to his isolated state, for the purpose of similarly studying other conditions which, in real life are found in combination or conflict. The objection to this method lies in the difficulty of the return from the abstract study to the actual facts; and this is probably an insuperable one in regard to most of its applications. The investigation, however, leads to trustworthy conclusions as to the conditions of the succession of different systems of land economy. The book abounds in calculations relating to agricultural expenditure and income, which diminish its interest to the general reader, though they are considered valuable to the specialist. They embody the results of the practical experience of the author on his estate of Tellow in Mecklenburg-Schwerin. Von Thünen was strongly impressed with the danger of a violent conflict between the middle class and the proletariat, and studied earnestly the question of wages, which he was one of the first to regard, not merely as the price of the commodity labor, but as the means of subsistence of the mass of the community. He arrived by mathematical reasonings of some complexity at a formula which expresses the amount of "natural wages" as $= \sqrt{ap}$, where a is the necessary expenditure of the laborer for subsistence, and p is the product of his labor. To this formula he attributed so much importance that he directed it to be engraved on his tomb. It implies that wages ought to rise with the amount of the product; and this conclusion led him to establish on his estate a system of participation by the laborers in the profits of farming, of which some account will be found in Mr. Sedley Taylor's *Profit-sharing between Capital and Labor* (1884). Von Thünen deserves more attention than he has received in England; both as a man and as a writer he was eminently interesting and original; and there is much in *Der Isolierte Staat* and his other works that is awakening and suggestive.

Roscher recognizes what he calls a Germano-Russian (deutsch-russische) school of political economy, represented principally by Heinrich Storch (1766-1825). Mercantilist principles had been preached by a native ("autochthonen") economist, Ivan Possoschkoff, in the time of Peter the Great. The new ideas of the Smithian system were introduced into Russia by Christian von Schlözer (1774-1831) in his professorial lectures and in his *Anfangsgründe der Staatswirtschaft, oder die Lehre von National-reichthume* (1805-1807). Storch was instructor in economic science of the future emperor Nicholas and his brother the grand-duke Michael, and the substance of his lessons to them is contained in his *Cours d'Économie Politique* (1815). The translation of this treatise into Russian was prevented by the censorship; Rau published a German version of it, with annotations, in 1819. It is a work of a very high order of merit. The epithet "deutsch-russisch" seems little applicable to Storch; as Roscher himself says, he follows mainly English and French writers—Say, Sismondi, Turgot, Bentham, Steuart, and Hume, but, above all, Adam Smith. His personal position (and the same is true of Schlözer) led him to consider economic doctrines in connection with a stage of culture different from that of the Western populations amongst which they had been for-

¹ The first German version of the *Wealth of Nations* was that by Johann Friedrich Schiller, published 1776-78. The second, which is the first good one, was by Christian Garve (1794, and again 1799 and 1810). A recent one by C. W. Asher (1861) is highly commended.

mulated; this change of the point of view opened the door to relativity, and helped to prepare the historical method. Storch's study of the economic and moral effects of serfdom is regarded as especially valuable. The general subjects with which he has particularly connected his name are (1) the doctrine of immaterial commodities (or elements of national prosperity), such as health, talent, morality, and the like; (2) the question of "productive" and "unproductive," as characters of labor and of consumption, on which he disagreed with Smith and may have furnished indications to Dunoyer; and (3) the differences between the revenue of nations and that of individuals, on which he follows Lauderdale and is opposed to Say. The latter economist having published at Paris (1823) a new edition of Storch's *Cours*, with criticisms sometimes offensive in tone, he published by way of reply to some of Say's strictures what is considered his ripest and scientifically most important work, *Considérations sur la nature du Revenu National* (1824; translated into German by the author himself, 1825).

A distinct note of opposition to the Smithian economics was sounded in Germany by two writers, who setting out from somewhat different points of view, animated by different sentiments, and favoring different practical systems, yet so far as their criticisms are concerned, arrive at similar conclusions; we mean Adam Müller and Frederick List.

Adam Müller (1779-1829) was undoubtedly a man of real genius. In his principal work *Elemente der Staatskunst* (1809), and his other writings, he represents a movement of economic thought which was in relation with the (so-called) Romanic literature of the period. The reaction against Smithianism of which he was the coryphæus was founded on an attachment to the principles and social system of the Middle Ages. It is possible that the political and historical ideas which inspire him, his repugnance to contemporary liberalism; and his notions of regular organic development, especially in relation to England, were in some degree imbibed from Edmund Burke, whose *Reflections on the Revolution in France* had been translated into German by Frederick Gentz, the friend and teacher of Müller. The association of his criticisms with mediæval prepossessions ought not to prevent our recognizing the elements of truth which they contain.

He protests against the doctrine of Smith and against modern political economy in general on the ground that it presents a mechanical, atomistic, and purely material conception of society, that it reduces to nullity all moral forces and ignores the necessity of a moral order, that it is at bottom no more than a theory of private property and private interests, and takes no account of the life of the people as a whole in its national solidarity and historical continuity. Exclusive attention, he complains, is devoted to the immediate production of objects possessing exchange-value and to the transitory existence of individuals; whilst to the maintenance of the collective production for future generations, to intellectual products, powers, possessions, and enjoyments, and to the state with its higher tasks and aims, scarcely a thought is given. The truth is that nations are specialized organisms with distinct principles of life, having definite individualities which determine the course of their historical development. Each is through all time one whole; and, as the present is the heir of the past, it ought to keep before it constantly the permanent good of the community in the future. The economic existence of a people is only one side or province of its entire activity, requiring to be kept in harmony with the higher ends of society; and the proper organ to effect this reconciliation is the state, which, instead of being merely an apparatus for the administration of justice, represents the totality of the national life. The division of labor, Müller holds, is imperfectly developed by Smith, who makes it to arise out of a native bent for truck or barter; whilst its dependence on capital—on the labors and accumulations of past generations—is not duly emphasized, nor is the necessary counterpoise and completion of the division of labor, in the principle of the national combination of labor, properly brought out. Smith recognizes only material, not spiritual, capital; yet the latter, represented in every nation by language, as

the former by money, is a real national store of experience, wisdom, good sense, and moral feeling, transmitted with increase by each generation to its successor, and enables each generation to produce immensely more than by its own unaided powers it could possibly do. Again the system of Smith is one-sidedly British; if it is innocuous on the soil of England, it is because in her society the old foundations on which the spiritual and material life of the people can securely rest are preserved in the surviving spirit of feudalism and the inner connection of the whole social system—the national capital of laws, manners, reputation, and credit, which has been handed down in its integrity in consequence of the insular position of the country. For the continent of Europe a quite different system is necessary, in which, in place of the sum of the private wealth of individuals being viewed as the primary object, the real wealth of the nation and the production of national power shall be made to predominate, and along with the division of labor its national union and concentration—along with the physical, no less the intellectual and moral, capital shall be embraced. In these leading traits of Müller's thought there is much which foreshadows the more recent forms of German economic and sociological speculation, especially those characteristic of the "Historical" school.

Another element of opposition was represented by Friedrich List (1798-1846), a man of great intellectual vigor as well as practical energy, and notable as having powerfully contributed by his writings to the formation of the German Zollverein. His principal work is entitled *Das Nationale System der Politischen Oekonomie* (1841; 6th ed., 1877). Though his practical conclusions were different from Müller's, he was largely influenced by the general mode of thinking of that writer and by his strictures on the doctrine of Smith. It was particularly against the cosmopolitan principle in the modern economical system that he protested, and against the absolute doctrine of free trade, which was in harmony with that principle. He gave prominence to the national idea, and insisted on the special requirements of each nation according to its circumstances and especially to the degree of its development.

He refuses to Smith's system the title of the industrial, which he thinks more appropriate to the mercantile system, and designates the former as "the exchange-value system." He denies the parallelism asserted by Smith between the economic conduct proper to an individual and to a nation, and holds that the immediate private interest of the separate members of the community will not lead to the highest good of the whole. The nation is an existence, standing between the individual and humanity, and formed into a unity by its language, manners, historical development, culture, and constitution. This unity is the first condition of the security, well being, progress, and civilization of the individual; and private economic interests, like all others, must be subordinated to the maintenance, completion, and strengthening of the nationality. The nation having a continuous life, its true wealth consists—and this is List's fundamental doctrine—not in the quantity of exchange-values which it possesses, but in the full and many-sided development of its productive powers. Its economic education, if we may so speak, is more important than the immediate production of values, and it may be right that the present generation should sacrifice its gain and enjoyment to secure the strength and skill of the future. In the sound and normal condition of a nation which has attained economic maturity, the three productive powers of agriculture, manufactures, and commerce should be alike developed. But the two latter factors are superior in importance, as exercising a more effective and fruitful influence on the whole culture of the nation, as well as on its independence. Navigation, railways, all higher technical arts, connect themselves specially with these factors; whilst in a purely agricultural state there is a tendency to stagnation, absence of enterprise, and the maintenance of antiquated prejudices. But for the growth of the higher forms of industry all countries are not adapted—only those of the temperate zones, whilst the torrid regions have a natural monopoly in the production of certain raw materials; and thus between these two groups of countries a division of labor and confederation of powers spontaneously takes place. List then goes on to explain his theory of the stages of economic development through which the nations of the temperate zone, which are furnished with all the necessary conditions, naturally pass, in advancing to their normal

economic state. These are (1) pastoral life, (2) agriculture, (3) agriculture united with manufactures; whilst in the final stage agriculture, manufactures, and commerce are combined. The economic task of the state is to bring into existence through legislative and administrative action the conditions required for the progress of the nation through these stages. Out of this view arises List's scheme of industrial politics. Every nation, according to him, should begin with free trade, stimulating and improving its agriculture by intercourse with richer and more cultivated nations, importing foreign manufactures and exporting raw products. When it is economically so far advanced that it can manufacture for itself, then a system of protection should be employed to allow the home industries to develop themselves fully, and save them from being overpowered in their earlier efforts by the competition of more matured foreign industries in the home market. When the national industries have grown strong enough no longer to dread this competition, then the highest stage of progress has been reached; free trade should again become the rule, and the nation be thus thoroughly incorporated with the universal industrial union. In List's time, according to his view, Spain, Portugal, and Naples were purely agricultural countries; Germany and the United States of North America had arrived at the second stage, their manufactures being in process of development; France was near the boundary of the third or highest stage, which England alone had reached. For England, therefore, as well as for the agricultural countries first-named, free trade was the right economic policy, but not for Germany or America. What a nation loses for a time in exchange-values during the protective period she much more than gains in the long run in productive power,—the temporary expenditure being strictly analogous, when we place ourselves at the point of view of the life of the nation, to the cost of the industrial education of the individual. The practical conclusion which List drew for his own country was that she needed for her economic progress an extended and conveniently bounded territory reaching to the sea-coast both on north and south, and a vigorous expansion of manufactures and commerce, and that the way to the latter lay through judicious protective legislation with a customs union comprising all German lands, and a German marine with a Navigation Act. The national German spirit, striving after independence and power through union, and the national industry, awakening from its lethargy and eager to recover lost ground, were favorable to the success of List's book, and it produced a great sensation. He ably represented the tendencies and demands of his time in his own country; his work had the effect of fixing the attention, not merely of the speculative and official classes, but of practical men generally, on questions of political economy; and he had without doubt an important influence on German industrial policy. So far as science is concerned, the emphasis he laid on the relative historical study of stages of civilization as affecting economic questions, and his protest against absolute formulas, had a certain value; and the preponderance given to the national development over the immediate gains of individuals was sound in principle; though his doctrine was, both on its public and private sides, too much of a mere chrematistic, and tended in fact to set up a new form of mercantilism, rather than to aid the contemporary effort towards social reform.

Most of the writers at home or abroad hitherto mentioned continued the traditions of the school of Smith, only developing his doctrine in particular directions, sometimes not without one-sidedness or exaggeration, or correcting minor errors into which he had fallen, or seeking to give to the exposition of his principles more of order and lucidity. Some assailed the abuse of abstraction by Smith's successors, objected to the conclusions of Ricardo and his followers their non-accordance with the actual facts of human life, or protested against the anti-social consequences which seemed to result from the application of the (so-called) orthodox formulas. A few challenged Smith's fundamental ideas, and insisted on the necessity of altering the basis of general philosophy on which his economics ultimately rest. But, notwithstanding various premonitory indications, nothing substantial, at least nothing effective, was done, within the field we have as yet surveyed, towards the establishment of a really new order of thinking, or new mode of proceeding, in this branch of inquiry. Now, however, we have to describe a great and growing movement, which has already considerably changed the whole character of

the study in the conceptions of many, and which promises to exercise a still more potent influence in the future. We mean the rise of the Historical School, which we regard as marking the third epoch in the modern development of economic science.

THE HISTORICAL SCHOOL.

The negative movement which filled the 18th century had for its watchword on the economic side the liberation of industrial effort from both feudal survivals and Governmental fetters. But in all the aspects of that movement, the economic as well as the rest, the process of demolition was historically only the necessary preliminary condition of a total renovation, towards which western Europe was energetically tending, though with but an indistinct conception of its precise nature. The disorganization of the body of opinion which underlay the old system outran the progress towards the establishment of new principles adequate to form a guidance in the future. The critical philosophy which had wrought the disorganization could only repeat its formulas of absolute liberty, but was powerless for reconstruction. And hence there was seen throughout the West, after the French explosion, the remarkable spectacle of a continuous oscillation between the tendency to recur to outworn ideas and a vague impulse towards a new order in social thought and life, this impulse often taking an anarchical character.

From this state of oscillation, which has given to our century its equivocal and transitional aspect, the only possible issue was in the foundation of a scientific social doctrine which should supply a basis for the gradual convergence of opinion on human questions. The foundation of such a doctrine is the immortal service for which the world is indebted to Auguste Comte.

The leading features of sociology, as he conceived it, are the following: (1) it is essentially *one science*, in which all the elements of a social state are studied in their relations and mutual actions; (2) it includes a dynamical as well as a static theory of society; (3) it thus eliminates the absolute, substituting for an imagined fixity the conception of ordered change; (4) its principal method, though others are not excluded, is that of historical comparison; (5) it is pervaded by moral ideas, by notions of social duty, as opposed to the individual rights which were derived as corollaries from the *jus naturæ*; and (6) in its spirit and practical consequences it tends to the realization of all the great ends which compose "the popular cause"; yet (7) it aims at this through peaceful means, replacing revolution by evolution. The several characteristics we have enumerated are not independent; they may be shown to be vitally connected with each other. Several of these features must now be more fully described; the others will meet us before the close of the present survey.

In the masterly exposition of sociological method which is contained in the fourth volume of the *Philosophie Positive* (1839),¹ Comte marks out the broad division between social statics and social dynamics—the former studying the laws of social coexistence, the latter those of social development. The fundamental principle of the former is the general consensus between the several social organs and functions, which, without unduly pressing a useful analogy, we may regard as resembling that which exists between the several organs and functions of an animal body. The study of dynamical is different from, and necessarily subordinated to, that of statical sociology, progress being in fact the development of order, just as the study of evolution in biology is different from, and

¹ He had already in 1822 stated his fundamental principles in an opusculum which is reproduced in the Appendix to his *Politique Positive*.

subordinated to, that of the structures and functions which are exhibited by evolution as they exist at the several points of an ascending scale. The laws of social co-existence and movement are as much subjects for observation as the corresponding phenomena in the life of an individual organism. For the study of development in particular, a modification of the comparative method familiar to biologists will be the appropriate mode of research. The several successive stages of society will have to be systematically compared, in order to discover their laws of sequence, and to determine the filiation of their characteristic features.

Though we must take care that both in our statical and dynamical studies we do not ignore or contradict the fundamental properties of human nature, the project of deducing either species of laws from those properties independently of direct observation is one which cannot be realized. Neither the general structure of human society nor the march of its development could be so predicted. This is especially evident with respect to dynamical laws, because, in the passage of society from one phase to another, the preponderating agency is the accumulated influence of past generations, which is much too complex to be investigated deductively—a conclusion which it is important to keep steadily before us now that some of the (so-called) anthropologists are seeking to make the science of society a mere annex and derivative of biology. The principles of biology unquestionably lie at the foundation of the social science, but the latter has, and must always have, a field of research and a method of inquiry peculiar to itself. The field is history in the largest sense, including contemporary fact; and the principal, though not exclusive, method is, as we have said, that process of sociological comparison which is most conveniently called the historical method.

These general principles affect the economic no less than other branches of social speculation; and with respect to that department of inquiry they lead to important results. They show that the idea of forming a true theory of the economic frame and working of society apart from its other sides is illusory. Such study is indeed provisionally indispensable, but no rational theory of the economic organs and functions of society can be constructed if they are considered as isolated from the rest. In other words, a separate economic science is, strictly speaking, an impossibility, as representing only one portion of a complex organism, all whose parts and their actions are in a constant relation of correspondence and reciprocal modification. Hence, too, it will follow that, whatever useful indications may be derived from our general knowledge of individual human nature, the economic structure of society and its mode of development cannot be deductively foreseen, but must be ascertained by direct historical investigation. We have said "its mode of development"; for it is obvious that, as of every social element, so of the economic factor in human affairs, there must be a dynamical doctrine, a theory of the successive phases of the economic condition of society; yet in the accepted systems this was a desideratum, nothing but some partial and fragmentary notions on this whole side of the subject being yet extant. And, further, the economic structure and working of one historic stage being different from those of another, we must abandon the idea of an absolute system possessing universal validity, and substitute that of a series of such systems, in which, however, the succession is not at all arbitrary, but is itself regulated by law.

Though Comte's enterprise was a constructive one, his aim being the foundation of a scientific theory of society, he could not avoid criticising the labors of those who before him had treated several branches of social inquiry. Amongst them the economists were necessarily considered; and he urged or implied, in various places of his above-named work, as well as

of his *Politique Positive*, objections to their general ideas and methods of procedure essentially the same with those which we stated in speaking of Ricardo and his followers. J. S. Mill shows himself much irritated by these comments, and remarks on them as showing "how extremely superficial M. Comte" (whom he yet regards as a thinker quite comparable with Descartes and Leibnitz) "could sometimes be"—an unfortunate observation, which he would scarcely have made if he could have foreseen the subsequent march of European thought, and the large degree in which the main points of Comte's criticism have been accepted or independently reproduced.

Germany.—The second manifestation of this new movement in economic science was the appearance of the German historical school. The views of this school do not appear to have arisen, like Comte's theory of sociological method, out of general philosophic ideas; they seem rather to have been suggested by an extension to the economic field of the conceptions of the historical school of jurisprudence of which Savigny was the most eminent representative. The juristic system is not a fixed social phenomenon, but is variable from one stage in the progress of society to another—it is in vital relation with the other coexistent social factors; and what is, in the jurist's sphere, adapted to one period of development is often unfit for another. These ideas were seen to be applicable to the economic system also; the relative point of view was thus reached, and the absolute attitude was found to be untenable. Cosmopolitanism in theory, or the assumption of a system equally true of every country, and what has been called perpetualism, or the assumption of a system applicable to every social stage, were alike discredited. And so the German historical school appears to have taken its rise.

Omitting preparatory indications and undeveloped germs of doctrine, we must trace the origin of the school to Wilhelm Roscher. Its fundamental principles are stated, though with some hesitation, and with an unfortunate contrast of the historical with the "philosophical" method,¹ in his *Grundriss zu Vorlesungen über die Staatswirtschaft nach geschichtlicher Methode* (1843). The following are the leading heads insisted on in the preface to that work.

"The historical method exhibits itself not merely in the external form of a treatment of phenomena according to their chronological succession, but in the following fundamental ideas. (1) The aim is to represent what nations have thought, willed, and discovered in the economic field, what they have striven after and attained, and why they have attained it. (2) A people is not merely the mass of individuals now living; it will not suffice to observe contemporary facts. (3) All the peoples of whom we can learn anything must be studied and compared from the economic point of view, especially the ancient peoples, whose development lies before us in its totality. (4) We must not simply praise or blame economic institutions; but few of them have been salutary or detrimental to all peoples and at all stages of culture; rather it is a principal task of science to show how and why, out of what was once reasonable and beneficent, the unwise and inexpedient has often gradually arisen." Of the principles enunciated in this paraphrase of Roscher's words a portion of the third alone seems open to objection; the economy of ancient peoples is not a more important subject of study than that of the moderns; indeed the question of the relative importance of the two is one that ought not to be raised. For the essential condition of all sound sociological inquiry is the comparative consideration of the entire series of the most complete evolution known to history—that, namely, of the group of nations forming what is known as the Occidental

¹ This phraseology was probably borrowed from the controversy on the method of jurisprudence between Thibault on the one hand and Savigny and Hugo on the other.

Commonwealth, or, more briefly, "the West." The reasons for choosing this social series, and for provisionally restricting our studies almost altogether to it, have been stated with unanswerable force by Comte in the *Philosophie Positive*. Greece and Rome are, indeed, elements in the series; but it is the development as a whole, not any special portions of it, that sociology must keep in view in order to determine the laws of the movement,—just as, in the study of biological evolution, no one stage of an organism can be considered as of preponderating importance, the entire succession of changes being the object of research. Of Roscher's further eminent services we shall speak hereafter; he is now mentioned only in relation to the origin of the new school.

In 1848 Bruno Hildebrand published the first volume of a work, which, though he lived for many years after (d. 1878), he never continued, entitled *Die Nationalökonomie der Gegenwart und Zukunft*. Hildebrand was a thinker of a really high order; it may be doubted whether amongst German economists there has been any endowed with a more profound and searching intellect. He is quite free from the wordiness and obscurity which too often characterize German writers, and traces broad outlines with a sure and powerful hand. His book contains a masterly criticism of the economic systems which preceded, or belonged to, his time, including those of Smith, Müller, List, and the socialists. But it is interesting to us at present mainly from the general position he takes up, and his conception of the real nature of political economy. The object of his work, he tells us, is to open a way in the economic domain to a thorough historical direction and method, and to transform the science into a doctrine of the laws of the economic development of nations. It is interesting to observe that the type which he sets before him in his proposed reform of political economy is not that of historical jurisprudence, but of the science of language as it has been reconstructed in the present century, a selection which indicates the comparative method as the one which he considered appropriate. In both sciences we have the presence of an ordered variation in time, and the consequent substitution of the relative for the absolute.

In 1853 appeared the work of Karl Knies, entitled *Die Politische Oekonomie vom Standpunkte der geschichtlichen Methode*. This is an elaborate exposition and defence of the historical method in its application to economic science, and is the most systematic and complete manifesto of the new school, at least on the logical side. The fundamental propositions are that the economic constitution of society at any epoch on the one hand, and on the other the contemporary theoretic conception of economic science, are results of a definite historical development; that they are both in vital connection with the whole social organism of the period, having grown up along with it and under the same conditions of time, place, and nationality; that the economic system must therefore be regarded as passing through a series of phases correlative with the successive stages of civilization, and can at no point of this movement be considered to have attained an entirely definitive form; that no more the present than any previous economic organization of society is to be regarded as absolutely good and right, but only as a phase in a continuous historical evolution; and that in like manner the now prevalent economic doctrine is not to be viewed as complete and final, but only as representing a certain stage in the unfolding or progressive manifestation of the truth.

The theme of the book is handled with, perhaps, an undue degree of expansion and detail. The author exhibits much sagacity as well as learning, and criticises effectively the errors, inconsistencies, and exaggerations of his predecessors. But in characterizing and vindicating the historical method he has

added nothing to Comte. A second edition of his treatise was published in 1883, and in this he makes the singular confession that, when he wrote in 1852, the *Philosophie Positive*, the six volumes of which had appeared from 1830 to 1842, was entirely unknown to him and, he adds, probably to all German economists. This is not to the credit of their open-mindedness or literary vigilance, if we remember that Mill was already in correspondence with Comte in 1841, and that his eulogistic notice of him in the *Logic* appeared in 1843. When, however, Knies at a later period examined Comte's work, he was, he tells us, surprised at finding in it so many anticipations of, or "parallelisms" with, his own conclusions. And well he might; for all that is really valuable in his methodology is to be found in Comte, applied on a larger scale, and designed with the broad and commanding power which marks the *du majores* of philosophy.

There are two points which seem to be open to criticism in the position taken by some German economists of the historical school.

1. Knies and some other writers, in maintaining the principle of relativity in economic theory, appear not to preserve the due balance in one particular. The two forms of absolutism in doctrine, cosmopolitanism and what Knies calls perpetualism, he seems to place on exactly the same footing; in other words, he considers the error of overlooking varieties of local circumstances and nationality to be quite as serious as that of neglecting differences in the stage of historical development. But this is certainly not so. In every branch of sociology the latter is much the graver error, vitiating radically, wherever it is found, the whole of our investigations. If we ignore the fact, or mistake the direction, of the social movement, we are wrong in the most fundamental point of all—a point, too, which is involved in every question. But the variations depending on difference of race, as affecting bodily and mental endowment, or on diversity of external situation, are secondary phenomena only; they must be postponed in studying the general theory of social development, and taken into account afterwards when we come to examine the modifications in the character of the development arising out of peculiar conditions. And, though the physical nature of a territory is a condition which is likely to operate with special force on economic phenomena, it is rather on the technical forms and comparative extension of the several branches of industry that it will act than on the social conduct of each branch, or the co-ordination and relative action of all, which latter are the proper subjects of the inquiries of the economist.

2. Some members of the school appear, in their anxiety to assert the relativity of the science, to fall into the error of denying economic laws altogether; they are at least unwilling to speak of "natural laws" in relation to the economic world. From a too exclusive consideration of law in the inorganic sphere, they regard this phraseology as binding them to the notion of fixity and of an invariable system of practical economy. But, if we turn our attention rather to the organic sciences, which are more kindred to the social, we shall see that the term "natural law" carries with it no such implication. As we have more than once indicated, an essential part of the idea of life is that of development, in other words, of "ordered change." And that such a development takes place in the constitution and working of society in all its elements is a fact which cannot be doubted, and which these writers themselves emphatically assert. That there exist between the several social elements such relations as make the change of one element involve or determine the change of another is equally plain; and why the name of natural laws should be denied to such constant relations of coexistence and succession it is not easy to see. These laws, being universal, admit of the construction of an abstract theory of economic development; whilst a part of the German historical school tends to substitute for such a theory a mere description of different national economies, introducing prematurely—as we have pointed out—the action of special territorial or ethnological conditions, instead of reserving this as the ground of later modifications, in concrete cases, of the primary general laws deduced from a study of the common human evolution.

To the three writers above named, Roscher, Hildebrand, and Knies, the foundation of the German historical school of political economy belongs. It does not appear that Roscher in his own subsequent labors has been much under the influence of the method which he has in so many places

admirably characterized. In his *System der Volkswirtschaft* (vol. i., *Grundlagen der Nationalökonomie*, 1854, 15th ed., 1880; vol. ii., *N. O. des Ackerbaues*, 1860, 10th ed., 1882; vol. iii., *N. O. des Handels und Gewerbfleisses*, 3d ed., 1882) the dogmatic and the historical matter are rather juxtaposed than vitally combined. It is true that he has most usefully applied his vast learning to special historical studies, in relation especially to the progress of the science itself. His treatise *Ueber das Verhältniss der Nationalökonomie zum klassischen Alterthum*, his *Zur Geschichte der Englischen Volkswirtschaftslehre* (Leipsic, 1851-2), and, above all, that marvellous monument of erudition and industry, his *Geschichte der National-Ökonomie in Deutschland* (1874), to which he is said to have devoted fifteen years of study, are among the most valuable extant works of this kind, though the last by its accumulation of detail is unfitted for general study outside of Germany itself. Several interesting and useful monographs are collected in his *Ansichten der Volkswirtschaft vom geschichtlichen Standpunkte* (3d ed., 1878). His systematic treatise, too, above referred to, abounds in historical notices of the rise and development of the several doctrines of the science. But it cannot be alleged that he has done much towards the transformation of political economy which his earliest labors seemed to announce; and Cossa appears to be right in saying that his dogmatic work has not effected any substantial modification of the principles of Hermann and Rau.

The historical method has exhibited its essential features more fully in the hands of the younger generation of scientific economists in Germany, amongst whom may be reckoned Lujo Brentano, Adolf Held, Erwin Nasse, Gustav Schmoller, H. Rösler, Albert Schäffle, Hans von Scheel, Gustav Schönberg, and Adolf Wagner. Besides the general principle of an historical treatment of the science, the leading ideas which have been most strongly insisted on by this school are the following: I. The necessity of accentuating the moral element in economic study. This consideration has been urged with special emphasis by Schmoller in his *Grundfragen* (1875) and by Schäffle in his *Das gesellschaftliche System der menschlichen Wirtschaft* (3d ed., 1873). G. Kries (d. 1858) appears also to have handled the subject well in a review of J. S. Mill. According to the most advanced organs of the school, three principles of organization are at work in practical economy; and, corresponding with these, there are three different systems or spheres of activity. The latter are (1) private economy; (2) the compulsory public economy; (3) the "caritative" sphere. In the first alone personal interest predominates; in the second the general interest of the society; in the third the benevolent impulses. Even in the first, however, the action of private interest cannot be unlimited; not to speak here of the intervention of the public power, the excesses and abuses of the fundamental principle in this department must be checked and controlled by an economic morality, which can never be left out of account in theory any more than in practical applications. In the third region above named, moral influences are of course supreme. II. The close relation which necessarily exists between economics and jurisprudence. This has been brought out by L. von Stein and H. Rösler, but is most systematically established by Wagner—who is, without doubt, one of the most eminent of living German economists—especially in his *Grundlegung*, now forming part of the *Lehrbuch der politischen Ökonomie* in course of publication by him and Professor Nasse jointly. The doctrine of the *jus naturæ*, on which the physiocrats, as we have seen, reared their economic structure, has lost its hold on belief, and the old *a priori* and absolute conceptions of personal freedom and property have given way along with it. It is seen that the economic position of the individual, instead of depending merely on so-called natural rights or even on his natural powers, is conditioned by the contemporary juristic system, which is itself an historical product. The above-named conceptions, therefore, half economic, half juristic, of freedom and property require a fresh examination. It is principally from this point of

view that Wagner approaches economic studies. The point, as he says, on which all turns is the old question of the relation of the individual to the community. Whoever with the older juristic and political philosophy and national economy places the individual in the centre comes necessarily to the untenable results which, in the economic field, the physiocratic and Smithian school of free competition has set up.

Wagner on the contrary investigates, before anything else, the conditions of the economic life of the community, and, in subordination to this, determines the sphere of the economic freedom of the individual. III. A different conception of the functions of the state from that entertained by the school of Smith. The latter school has in general followed the view of Rousseau and Kant that the sole office of the state is the protection of the members of the community from violence and fraud. This doctrine, which was in harmony with those of the *jus naturæ* and the social contract, was temporarily useful for the demolition of the old economic system with its complicated apparatus of fetters and restrictions. But it could not stand against a rational historical criticism, and still less against the growing practical demands of modern civilization. In fact, the abolition of the impolitic and discredited system of European Governments, by bringing to the surface the evils arising from unlimited competition, irresistibly demonstrated the necessity of public action according to new and more enlightened methods. The German historical school recognizes the state as not merely an institution for the maintenance of order, but as the organ of the nation for all ends which cannot be adequately effected by voluntary individual effort. Whenever social aims can be attained only or most advantageously through its action, that action is justified. The cases in which it can properly interfere must be determined separately on their own merits and in relation to the stage of national development. It ought certainly to promote intellectual and æsthetic culture. It ought to enforce provisions for public health and regulations for the proper conduct of production and transport. It ought to protect the weaker members of society, especially women, children, the aged, and the destitute, at least in the absence of family maintenance and guardianship. It ought to secure the laborer against the worst consequences of personal injury not due to his own negligence, to assist through legal recognition and supervision the efforts of the working classes for joint no less than individual self-help, and to guarantee the safety of their earnings, when entrusted to its care.

A special influence which has worked on this more recent group is that of theoretic socialism; we shall see hereafter that socialism as a party organization has also affected their practical policies. With such writers as St. Simon, Fourier, and Proudhon, Lassalle, Marx, Engels, Marlo, and Rodbertus (who, notwithstanding a recent denial, seems rightly described as a socialist) we do not deal in the present sketch (see SOCIALISM); but we must recognize them as having powerfully stimulated the younger German economists (in the strict sense of this last word). They have even modified the scientific conclusions of the latter, especially through criticism of the so-called orthodox system. Schäffle and Wagner may be especially named as having given a large space and a respectful attention to their arguments. In particular, the important consideration, to which we have already referred, that the economic position of the individual depends on the existing legal system, and notably on the existing organization of property, was first insisted on by the socialists. They had also pointed out that the present institutions of society in relation to property, inheritance, contract, and the like are (to use Lassalle's phrase) "historical categories which have changed, and are subject to further change," whilst in the orthodox economy they are generally assumed as a fixed order of things on the basis of which the indi-

vidual creates his own position. J. S. Mill called attention to the fact of the distribution of wealth depending, unlike its production, not on natural laws alone, but on the ordinances of society, but it is some of the German economists of the younger historical school who have most strongly emphasized this view. To rectify and complete the conception, however, we must bear in mind that those ordinances themselves are not arbitrarily changeable, but are conditioned by the stage of general social development.

In economic politics these writers have taken up a position between the German free-trade (or, as it is sometimes with questionable propriety called, the Manchester) party and the democratic socialists. The latter invoke the omnipotence of the state to transform radically and immediately the whole economic organization of society in the interest of the proletariat. The free-traders seek to minimize state action for any end except that of maintaining public order, and securing the safety and freedom of the individual. The members of the school of which we are now speaking, when intervening in the discussion of practical questions, have occupied an intermediate standpoint. They are opposed alike to social revolution and to rigid *laissez faire*. Whilst rejecting the socialistic programme, they call for the intervention of the state, in accordance with the theoretic principles already mentioned, for the purpose of mitigating the pressure of the modern industrial system on its weaker members, and extending in greater measure to the working classes the benefits of advancing civilization. Schäffle in his *Capitalismus und Socialismus* (1870; now absorbed into a larger work), Wagner in his *Rede über die sociale Frage* (1871), and Schönberg in his *Arbeitsämter: eine Aufgabe des deutschen Reichs* (1871) advocated this policy in relation to the question of the laborer. These expressions of opinion, with which most of the German professors of political economy sympathized, were violently assailed by the organs of the free-trade party, who found in them "a new form of socialism." Out of this arose a lively controversy; and, the necessity of a closer union and a practical political organization being felt amongst the partisans of the new direction, a congress was held at Eisenach in October, 1872, for the consideration of "the social question." It was attended by almost all the professors of economic science in the German universities, by representatives of the several political parties, by leaders of the working men, and by some of the large capitalists. At this meeting the principles above explained were formulated. Those who adopted them obtained from their opponents the appellation of "Katheder-Socialisten," or "socialists of the (professorial) chair," a nickname invented by H. B. Oppenheim, and which those to whom it was applied were not unwilling to accept. Since 1873 this group has been united in the "Verein für Socialpolitik," in which, as the controversy became mitigated, free-traders also have taken part. Within the Verein a division has shown itself. The left wing has favored a systematic gradual modification of the law of property in such a direction as would tend to the fulfilment of the socialistic aspirations, so far as these are legitimate, whilst the majority advocate reform through state action on the basis of existing jurial institutions. Schäffle goes so far as to maintain that the present "capitalistic" régime will be replaced by a socialistic organization; but, like J. S. Mill, he adjourns this change to a more or less remote future, and expects it as the result of a natural development, or process of "social selection";¹ he repudiates any immediate or violent revolution, and rejects any system of life which would set up "abstract equality" against the claims of individual service and merit.

The further the investigations of the German historical school have been carried in the several lines of inquiry it has opened, the more clearly it has come to light that the one thing needful is not merely a reform of political economy, but its fusion in a complete science of society. This is the view long since insisted on by Auguste Comte; and its justness is daily becoming more apparent. The best economists of Germany now tend strongly in this direction. Schäffle, who is largely under the influence of Comte and Herbert Spencer, has actually attempted the enterprise of widening economic into social studies. In his most important work, which had been prepared by previous publications, *Bau und Leben des socialen Körpers* (1875-1878; new ed., 1881), he proposes to give a comprehensive plan of an anatomy, physiology, and psychology of human society. He considers social processes as analogous to those of organic bodies; and sound and suggestive as the idea of this analogy, already used by Comte, undoubtedly is, he carries it, perhaps, to an undue degree of detail and elaboration. The same conception is adopted by P. von Lilienfeld in his *Gedanken über die Social wissenschaft der Zukunft* (1873-79). A tendency to the fusion of economic science in sociology is also found in Adolph Samter's *Soziallehre* (though the economic aspect of society is there specially studied) and in Schmoller's treatise *Ueber einige Grundfragen des Rechts und der Volkswirtschaftslehre*; and the necessity of such a transformation is energetically asserted by H. von Scheel in the preface to his German version (1879) of an English tract *On the present Position and Prospects of Political Economy*.

The name "Realistic," which has sometimes been given to the historical school, especially in its more recent form, appears to be injudiciously chosen. It is intended to mark the contrast with the "abstract" complexion of the orthodox economics. But the error of these economics lies, not in the use, but in the abuse of abstraction. All science implies abstraction, seeking, as it does, for unity in variety; the question in every branch is as to the right constitution of the abstract theory in relation to the concrete facts. Nor is the new school quite correctly distinguished as "inductive." Deduction doubtless unduly preponderates in the investigations of the older economists; but it must be remembered that it is a legitimate process, when it sets out, not from *a priori* assumptions, but from proved generalizations. And the appropriate method of economics, as of all sociology, is not so much induction as the specialized form of induction known as comparison, especially the comparative study of "social series" (to use Mill's phrase), which is properly designated as the "historical" method. If the denominations here criticized were allowed to prevail, there would be a danger of the school assuming an unscientific character. It might occupy itself too exclusively with statistical inquiry, and forget in the detailed examination of particular provinces of economic life the necessity of large philosophic ideas and of a systematic coördination of principles. So long as economics remain a separate branch of study, and until they are absorbed into sociology, the thinkers who follow the new direction will do wisely in retaining their original designation of the historical school.

The members of the historical school have produced many valuable works besides those which there has been occasion to mention above. Ample notices of their contributions to the several branches of the science, (including its applications) will be found dispersed through Wagner and Nasse's *Lehrbuch* and the comprehensive *Handbuch* edited by Schönberg. The following list, which does not pretend to approach to completeness, is given for the purpose of directing the student to a certain number of books which ought not to be overlooked in the study of the subjects to which they respectively refer:

¹ This should be remembered by readers of M. Leroy-Beaulieu's recent work on Collectivism (1884), in which he treats Schäffle as the principal theoretic representative of that form of socialism.

Knies, *Die Eisenbahnen und ihre Wirkungen* (1853), *Der Telegraph* (1857), *Geld und Credit* (1873-76-79); Rösler, *Zur Kritik der Lehre*

vom Arbeitslohn, 1861; Schmoller, *Zur Geschichte der deutschen Kleinindustrie im 19. Jahrh.*, 1870; Schäffle, *Theorie der ausschließenden Absatzverhältnisse* (1867), *Quintessenz des Sozialismus* (6th ed., 1878), *Grundsätze der Steuerpolitik* (1880); Nasse, *Mittelalterliche Feldgemeinschaft in England*, 1869; Brentano, *On the History and Development of Guilds*, prefixed to Toulmin Smith's *English Guilds* (1870), *Die Arbeiter gilden der Gegenwart* (1871-72), *Das Arbeitsverhältnis gemäss dem heutigen Recht* (1877), *Die Arbeitsversicherung gemäss der heutigen Wirtschaftsordnung* (1879), *Der Arbeitsvertragszwang* (1881); Held (born 1844, accidentally drowned in the Lake of Thun, 1880), *Die Einkommensteuer* (1872), *Die deutsche Arbeiterpresse der Gegenwart* (1873), *Sozialismus, Sozialdemokratie, und Sozialpolitik* (1878), *Grundriss für Vorlesungen über National-ökonomie* (2d ed., 1878); *Zwei Bücher zur sozialen Geschichte Englands* (posthumously published, 1881); Von Scheel (born 1839), *Die Theorie der sozialen Frage* (1871), *Unsere social-politischen Parteien* (1878). To these may be added L. Von Stein, *Die Verwaltungslehre* (1876-79), *Lehrbuch der Finanzwissenschaft* (4th ed., 1878). E. Dühring is the ablest of the few German followers of Carey; we shall mention his history hereafter. To the Russian-German school belongs the work of T. von Bernhardi, which is written from the historical point of view, *Veruch einer Kritik der Gründe welche für grosses und kleines Grundeigentum angeführt werden*, 1848. The free-trade school of Germany is recognized as having rendered great practical services in that country, especially by its systematic warfare against antiquated privileges and restrictions. Cobden has furnished the model of its political action, whilst, on the side of theory, it is founded chiefly on Say and Bastiat. The members of this school whose names have been most frequently heard by the English public are those of J. Prince Smith, who may be regarded as its head; H. von Treitschke, author of *Der Socialismus und seine Götter*, 1875 (directed against the Katheder-Socialisten); V. Böhmert, who has advocated the participation of workmen in profits (*Die Gewinnbetheiligung* (1878)); and J. H. Schultz-Delitzsch, well-known as the founder of the German popular banks, and a strenuous supporter of the system of "co-operation." The socialist writers, as has been already mentioned, are not included in the present historical survey, nor do we in general notice writings of the economists (properly so-called) having relation to the history of socialism or the controversy with it.

The movement which created this school in Germany, with the developments which have grown out of it, has without doubt given to that country at the present time the primacy in economic studies. German influence has been felt in the modification of opinion in other countries—most strongly, perhaps, in Italy, and least so in France. In England it has been steadily making way, though retarded by the insular indifference to the currents of foreign thought which has eminently marked our dominant school. Alongside of the influence thus exerted, a general distaste for the "orthodox" system has been spontaneously growing, partly from a suspicion that its method was unsound, and partly from a profound dissatisfaction with the practice it inspired, and the detected hollowness of the "Manchester" policy of mere *laissez faire*. Hence everywhere a mode of thinking and a species of research have shown themselves, and come into favor, which are in harmony with the systematic conceptions of the historical economists. Thus a dualism has established itself in the economic world, a younger school advancing towards predominance, whilst the old school still defends its position, though its adherents tend more and more to modify their attitude and to admit the value of the new lights.

Italy.—It is to be regretted that very little is known in England of the writings of the recent Italian economists. Luigi Cossa's *Guida*, which was translated at the suggestion of Jevons, has given us some notion of the character and importance of their labors. The urgency of questions of finance in Italy since its political renaissance has turned their researches for the most part into practical channels, and they have produced numerous monographs on statistical and administrative questions. But they have also dealt ably with the general doctrines of the science. Cossa pronounces Angelo Messedaglia (b. 1820), professor at Padua, to be the foremost of contemporary Italian economists; he has written on public loans (1850) and on population (1858), and is regarded as a master of the subjects of money and credit. His pupil Fedele Lampertico (b. 1833) is author of many writings, among which the most systematic and complete is his *Economia dei popoli e degli stati* (1874-1880). Marco Minghetti,¹ distinguished as a minister, is author, besides other writings, of *Economia pubblica e le sue attinenze colla morale e col diritto* (1859). Luigi Luzzati, also known as an able administrator, has by

several publications sought to prepare the way for reforms. The Sicilians Vito Cusumano and Giuseppe Ricca Salerno have produced excellent works: the former on the history of political economy in the Middle Ages (1876), and the economic schools of Germany in their relation to the social question (1875); the latter on the theories of capital, wages, and public loans (1877-8-9). Cossa, to whom we are indebted for most of these particulars, is himself author of several works which have established for him a high reputation, as his *Scienza delle Finanze* (1875; 3d ed., 1882), and his *Primi Elementi di Economia Politica* (1875; 4th. ed., 1878), which latter has been translated into several European languages.

Of greater interest than such an imperfect catalogue of writers is the fact of the appearance in Italy of the economic dualism to which we have referred as characterizing our time. There also the two schools—the old or so-called orthodox and the new or historical—with their respective modified forms, are found face to face. Cossa tells us that the instructors of the younger economists in northern Italy were publicly denounced in 1874 as Germanists, socialists, and corruptors of the Italian youth. In reply to this charge Luzzati, Lambertico, and Scialoja convoked in Milan the first congress of economists (1875) with the object of proclaiming their resistance to the idea which was sought to be imposed on them "that the science was born and died with Adam Smith and his commentators." M. de Laveleye's interesting *Lettres d'Italie* (1878-79) throw light on the state of economic studies in that country in still more recent years. Minghetti, presiding at the banquet at which M. de Laveleye was entertained by his Italian brethren, spoke of the "two tendencies" which had manifested themselves, and implied his own inclination to the new views. Carlo Ferraris, a pupil of Wagner, follows the same direction. Formal expositions and defences of the historical method have been produced by Schiattarella (*Del metodo in Economia Sociale*, 1875) and Cognetti de Martiis (*Della attinenze tra l'Economia Sociale e la Storia*, 1865). A large measure of acceptance has also been given to the historical method in learned and judicious monographs by Ricca Salerno (see especially his essay *Del metodo in Econ. Pol.*, 1878). Luzzati and Forti for some time edited a periodical, the *Giornale degli Economisti*, which was the organ of the new school, but which, we gather from Cossa, has ceased to appear. Cossa himself, whilst refusing his adhesion to this school on the ground that it reduces political economy to a mere narrative of facts,—an observation which, we must be permitted to say, betrays an entire misconception of its true principles,—admits that it has been most useful in several ways, and especially as having given the signal for a salutary, though, as he thinks, an excessive, reaction against the doctrinaire exaggerations of the older theorists.

France.—In France the historical school has not made so strong an impression,—partly, no doubt, because the extreme doctrines of the Ricardian system never obtained much hold there. It was by his recognition of its freedom from those exaggerations that Jevons was led to declare that "the truth is with the French school," whilst he pronounced our English economists to have been "living in a fool's paradise." National prejudice may also have contributed to the result referred to, the ordinary Frenchman being at present disposed to ask whether any good thing can come out of Germany. But, as we have shown, the philosophic doctrines on which the whole proceeding of the historical school is founded were first enunciated by a great French thinker, to whose splendid services most of his fellow-countrymen are singularly dead. Perhaps another determining cause is to be looked for in official influences, which in France, by their action on the higher education, impeded the free movement of independent conviction, as was seen notably in the temporary *éclat* they gave

¹ [A Bolognese, papal minister of education, went to Sardinia in 1848, was financial and prime minister of united Italy, wrote also of fine arts. Died December 10, 1886, aged sixty-eight years.—AM. Ed.]

on the wider philosophic stage to the shallow eclecticism of Cousin. The tendency to the historical point of view has appeared in France, as elsewhere; but it has shown itself not so much in modifying general doctrine as in leading to a more careful study of the economic opinions and institutions of the past.

Much useful work has been done by Frenchmen (with whom Belgians may here be associated) in the history of political economy, regarded either as a body of theory or as a system—or series of systems—of policy. Blanqui's history (1837-38) is not, indeed, entitled to a very high rank, but it was serviceable as a first general draught. That of Villeneuve-Bargemont (1839) was also interesting and useful, as presenting the Catholic view of the development and tendencies of the science. C. Perin's *Les doctrines économiques depuis un siècle* (1880) is written from the same point of view. A number of valuable monographs on particular statesmen or thinkers has also been produced by Frenchmen,—as, for example, that of A. Batbie, on Turgot (*Turgot Philosophe, Économiste, et Administrateur*, 1861); of Pierre Clément on Colbert (*Histoire de Colbert et de son Administration*, 2d ed., 1875); of H. Baudrillart on Bodin (*J. Bodin et son Temps; Tableau des Théories politiques et des Idées économiques au 16^e siècle*, 1853); of L. de Laveygne on the physiocrats (*Les Économistes Français du 18^e siècle*, 1870). Works, too, of real importance have been produced on particular aspects of the industrial development, as those of Léonce de Laveygne on the rural economy of France (1857), and of England, Scotland, and Ireland (1854). The treatise of Émile de Laveleye, *De la Propriété et de ses formes primitives* (1874; Eng. trans. by G. R. Marriott, 1878), is especially worthy of notice, not merely for its array of facts respecting the early forms of property, but because it co-operates strongly with the tendency of the new school to regard each stage of economic life from the relative point of view, as resulting from an historic past, harmonizing with the entire body of contemporary social conditions, and bearing in its bosom the germs of a future, predetermined in its essential character, though modifiable in its secondary dispositions.

M. de Laveleye has done much to call attention to the general principles of the historical school, acting in this way most usefully as an interpreter between Germany and France. But he appears in his most recent manifesto (*Les Lois naturelles et l'objet de l'Économie Politique*, 1883) to separate himself from the best members of that school, and to fall into positive error, when he refuses to economics the character of a true science (or department of a science) as distinguished from an art, and denies the existence of economic laws or tendencies independent of individual wills. Such a denial seems to involve that of social laws generally, which is a singularly retrograde attitude for a thinker of our time to take up, and one which cannot be excused since the appearance of the *Philosophie Positive*. The use of the metaphysical phrase "necessary laws" obscures the question; it suffices to speak of laws which do in fact prevail. M. de Laveleye relies on morals as supplying a parallel case, where we deal, not with natural laws, but with "imperative prescriptions," as if these prescriptions did not imply, as their basis, observed coexistences and sequences, and as if there were no such thing as moral evolution. He seems to be as far from the right point of view in one direction as his opponents of the old school in another. All that his arguments have really any tendency to prove is the proposition, undoubtedly a true one, that economic facts cannot be explained by a theory which leaves out of account the other social aspects, and therefore that our studies and expositions of economic phenomena must be kept in close relation with the conclusions of the larger science of society.

We cannot do more than notice in a general way some of the expository treatises of which there has been an almost continuous series from the time of Say downwards, or indeed from the date of Germain Garnier's *Abrégé des Principes de l'Économie Politique* (1796). That of Destutt de Tracy forms a portion of his *Éléments d'Idéologie* (1823). Droz brought out especially the relations of economics to morals and of wealth to human happiness (*Économie Politique*, 1829). Pellegrino Rossi,—an Italian, formed, however, as an economist by studies in Switzerland, professing the science in Paris, and writing in French (*Cours d'Économie Politique*, 1838-54),—gave in classic form an exposition of the doctrines of Say, Malthus, and Ricardo. Michel Chevalier (1806-1879), specially known in England by his tract, translated by Cobden, on the fall in the value of gold (*La Baisse d'Or*, 1858), gives in his *Cours d'Économie Politique* (1845-50) particularly valuable matter on the most recent industrial phenomena, and on money and the production of the precious metals. Henri Baudrillart, author of *Les*

Rapports de la Morale et de l'Économie Politique (1860, 2d ed., 1883), and of *Histoire du Luce* (1878), published in 1857 a *Manuel d'Économie Politique* (3d ed., 1872), which Cossa calls an "admirable compendium." Joseph Garnier (*Traité de l'Économie Politique*, 1860, 8th ed., 1880) in some respects follows Dunoyer. J. G. Courcelle-Seneuil, the translator of J. S. Mill, whom Prof. F. A. Walker calls "perhaps the ablest economist writing in the French language since J. B. Say," besides a *Traité théorique et pratique des opérations de Banque et Théorie des Entreprises Industrielles* (1856), wrote a *Traité de l'Économie Politique* (1858-59), which is held in much esteem. Finally, the Genevese, Antoine Elise Cherbuliez (d. 1869) was author of what Cossa pronounces to be the best treatise on the science in the French language (*Précis de la Science Économique*, 1862). L. Walras, in *Éléments d'Économie Politique pure* (1874-77), and *Théorie Mathématique de la Richesse Sociale* (1883), has followed the example of Cournot in attempting a mathematical treatment of the subject.

England.—Sacrificing the strict chronological order of the history of economics to deeper considerations, we have already spoken of Cairnes, describing him as the last original English writer who was an adherent of the old school pure and simple. Both in method and doctrine he was essentially Ricardian; though professing and really feeling profound respect for Mill, he was disposed to go behind him and attach himself rather to their common master. Mr. Sidgwick is doubtless right in believing that his *Leading Principles* did much to shake "the unique prestige which Mill's exposition had enjoyed for nearly half a generation," and in this, as in some other ways, Cairnes may have been a dissolving force, and tended towards radical change; but, if he exercised this influence, he did so unconsciously and involuntarily. Many influences had, however, for some time been silently sapping the foundations of the old system. The students of Comte had seen that its method was an erroneous one. The elevated moral teaching of Carlyle had disgusted the best minds with the low maxims of the Manchester school. Ruskin had not merely protested against the egoistic spirit of the prevalent doctrine, but had pointed to some of its real weaknesses as a scientific theory.¹ It began to be felt, and even its warmest partisans sometimes admitted, that it had done all the work, mainly a destructive one, of which it was capable. Cairnes himself declared that, whilst most educated people believed it doomed to sterility for the future, some energetic minds thought it likely to be a positive obstruction in the way of useful reform. Miss Martineau, who had in earlier life been a thorough Ricardian, came to think that political economy, as it had been elaborated by her contemporaries, was, strictly speaking, no science at all, and must undergo such essential change that future generations would owe little to it beyond the establishment of the existence of general laws in one department of human affairs. The instinctive repugnance of the working classes had continued, in spite of the efforts of their superiors to recommend its lessons to them—efforts which were perhaps not unfrequently dictated rather by class interest than by public spirit. All the symptoms boded impending change, but they were visible rather in general literature and in the atmosphere of social opinion than within the economic circle. But when it became known that a great movement had taken place, especially in Germany, on new and more hopeful lines, the English economists themselves began to recognize the necessity of a reform and even to further its advent. The principal agencies of this kind, in marshalling the way to a renovation of the science, have been those of Bagehot, Leslie, and Jevons,—the first limiting the sphere of the dominant system, while seeking to conserve it within narrower bounds; the second directly assailing it and setting up the new method as the rival and destined successor of the old; and the third acknowl-

¹ The remarkable book *Money and Morals*, by John Lalor, 1852, was written partly under the influence of Carlyle. There is a good monograph entitled *John Ruskin, Economist*, by P. Geddes, 1884.

edging the collapse of the hitherto reigning dynasty, proclaiming the necessity of an altered régime, and admitting the younger claimant as joint possessor in the future. Thus, in England too, the dualism which exists on the Continent has been established; and there is reason to expect that here more speedily and decisively than in France or Italy the historical school will displace its antagonist. It is certainly in England next after Germany that the preaching of the new views has been most vigorously and effectively begun.

Walter Bagehot (1826-1877) was author of an excellent work on the English money market and the circumstances which have determined its peculiar character (*Lombard Street*, 1873; 7th ed., 1878), and of several monographs on particular monetary questions, which his practical experience, combined with his scientific habits of thought, eminently fitted him to handle. On the general principles of economics he wrote some highly important essays collected in *Economic Studies* (edited by R. H. Hutton, 1880), the object of which was to show that the traditional system of political economy—the system of Ricardo and J. S. Mill—rested on certain fundamental assumptions, which, instead of being universally true in fact, were only realized within very narrow limits of time and space. Instead of being applicable to all states of society, it holds only in relation to those “in which commerce has largely developed, and where it has taken the form of development, or something like the form, which it has taken in England.” It is “the science of business such as business is in large and trading communities—an analysis of the great commerce by which England has become rich.” But more than this it is not; it will not explain the economic life of earlier times, nor even of other communities in our own time; and for the latter reason it has remained insular; it has never been fully accepted in other countries as it has been at home. It is, in fact, a sort of ready reckoner, enabling us to calculate roughly what will happen under given conditions in Lombard Street, on the Stock Exchange, and in the great markets of the world. It is a “convenient series of deductions from assumed axioms which are never quite true, which in many times and countries would be utterly untrue, but which are sufficiently near to the principal conditions of the modern” English “world to make it useful to consider them by themselves.”

Mill and Cairnes had already shown that the science they taught was a hypothetic one, in the sense that it dealt not with real but with imaginary men—“economic men” who were conceived as simply “money-making animals.” But Bagehot went further: he showed what those writers, though they may have indicated, had not clearly brought out,¹ that the world in which these men were supposed to act is also “a very limited and peculiar world.” What marks off this special world, he tells us, is the promptness of transfer of capital and labor from one employment to another, as determined by differences in the remuneration of those several employments—a promptness, about the actual existence of which in the contemporary English world he fluctuates a good deal, but which on the whole he recognizes as substantially realized.

Bagehot described himself as “the last man of the ante-Mill period,” having learned his economics from Ricardo; and the latter writer he appears to have to the end greatly over-estimated. But he lived long enough to gain some knowledge of the historical method, and with it he had “no quarrel, but rather much sympathy.” “Rightly conceived,” he said, “it is no rival to the abstract method rightly conceived.” We will not stop to criticize a second time the term “abstract method” here applied to that of the old school, or to insist on the truth that all science is necessarily abstract, the only question that can arise being

as to the just degree of abstraction, or, in general, as to the right constitution of the relation between the abstract and the concrete. It is more apposite to remark that Bagehot's view of the reconciliation of the two methods is quite different from that of most “orthodox” economists. They commonly treat the historical method with a sort of patronizing toleration as affording useful exemplifications or illustrations of their theorems. But, according to him, the two methods are applicable in quite different fields. For what he calls the “abstract” method he reserves the narrow, but most immediately interesting, province of modern advanced industrial life, and hands over to the historical the economic phenomena of all the human past and all the rest of the human present. He himself exhibits much capacity for such historical research, and in particular has thrown real light on the less-noticed economic and social effects of the institution of money, and on the creation of capital in the earlier stages of society. But his principal efficacy has been in reducing, by the considerations we have mentioned, still further than his predecessors had done, our conceptions of the work which the *a priori* method can do. He in fact dispelled the idea that it can ever supply the branch of general sociology which deals with wealth. As to the relations of economics to the other sides of sociology, he holds that the “abstract” science rightly ignores them. It does not consider the differences of human wants, or the social results of their several gratifications, except so far as these affect the production of wealth. In its view “a pot of beer and a picture—a book of religion and a pack of cards—are equally worthy of regard.” It therefore leaves the ground open for a science which will, on the one hand, study wealth as a social fact in all its successive forms and phases, and, on the other, will regard it in its true light as an instrument for the conservation and evolution—moral as well as material—of human societies.

Though it will involve a slight digression, it is desirable here to notice a further attenuation of the functions of the deductive method, which is well pointed out in Mr. Sidgwick's recent remarkable work on political economy. He observes that, whilst J. S. Mill declares that the method *a priori* is the true method of the science, and that “it has been so understood and taught by all its most distinguished teachers,” he yet himself in the treatment of production followed an inductive method (or at least one essentially different from the deductive), obtaining his results by “merely analyzing and systematizing our common empirical knowledge of the facts of industry.” To explain this characteristic inconsistency, Mr. Sidgwick suggests that Mill, in making his general statement as to method, had in contemplation only the statics of distribution and exchange. And in this latter field Mr. Sidgwick holds that the *a priori* method, if it be pursued with caution, if the simplified premises be well devised and the conclusions “modified by a rough conjectural allowance” for the elements omitted in the premises, is not, for the case of a developed industrial society, “essentially false or misleading.” Its conclusions are hypothetically valid, though “its utility as a means of interpreting and explaining concrete facts depends on its being used with as full a knowledge as possible of the results of observation and induction.” We do not think this statement need be objected to, though we should prefer to regard deduction from hypothesis as a useful occasional logical artifice, and, as such, perfectly legitimate in this as in other fields of inquiry, rather than as the main form of method in any department of economics. Mr. Sidgwick, by his limitation of deduction in distributional questions to “a state of things taken as the type to which civilized society generally approximates,” seems to agree with Bagehot that for times and places which do not correspond to this type the historical method must be used—a method which, be it observed, does not exclude, but positively implies, “reflective analysis” of the facts, and their interpretation from “the motives of human agents” as well as from other determining conditions. In the dynamical study of wealth—of the changes in its distribution no less than its production—Mr. Sidgwick admits that the method *a priori* “can occupy but a very subordinate place.” We should say that here also, though to a less extent, as a logical artifice it may sometimes be useful, though the hypotheses assumed ought not to be the same that are adapted

¹ Jones, whose writings were apparently unknown to Bagehot, had, as we have seen, in some degree anticipated him in this exposition.

to a mature industrial stage. But the essential organ must be the historical method, studying comparatively the different phases of social evolution.

Connected with the theory of modern industry is one subject which Bagehot treated, though only in an incidental way, much more satisfactorily than his predecessors,—namely, the function of the entrepreneur, who in Mill and Cairnes is scarcely recognized except as the owner of capital. It is quite singular how little, in the *Leading Principles* of the latter, his active co-operation is taken into account. Bagehot objects to the phrase “wages of superintendence,” commonly used to express his “reward,” as suggesting altogether erroneous ideas of the nature of his work, and well describes the large and varied range of his activity and usefulness, and the rare combination of gifts and acquirements which go to make up the perfection of his equipment. It can scarcely be doubted that a foregone conclusion in favor of the system of (so-called) co-operation has sometimes led economists to keep these important considerations in the background. They have been brought into due prominence of late in the treatises of Profs. Marshall and F. A. Walker, who, however, have scarcely made clear, and certainly have not justified, the principle on which the amount of the remuneration of the entrepreneur is determined.

We have seen that Jones had in his dogmatic teaching anticipated in some degree the attitude of the new school; important works had also been produced, notably by Thomas Tooke and William Newmarch (*History of Prices*, 1838–1857), and by James E. Thorold Rogers (*History of Agriculture and Prices in England*, 1866–82), on the course of English economic history. But the first systematic statement

by an English writer of the philosophic foundation of the historical method, as the appropriate organ of economic research, is to be found in an essay by T. E. Cliffe Leslie (printed in the Dublin University periodical, *Hermathena*, 1876; since included in his *Essays Moral and Political*, 1879). This essay was the most important publication on the logical aspect of economic science which had appeared since Mill's essay in his *Unsettled Questions*. Though Cairnes had expanded and illustrated the views of Mill, he had really added little to their substance. Leslie takes up a position directly opposed to theirs. He criticises with much force and verve the principles and practice of the “orthodox” school. Those who are acquainted with what has been written on this subject by Kries and other Germans will appreciate the freshness and originality of Leslie's treatment. He points out the loose and vague character of the principle to which the classical economists profess to trace back all the phenomena with which they deal—namely, the “desire of wealth.” This phrase really stands for a variety of wants, desires, and sentiments, widely different in their nature and economic effects, and undergoing important changes (as, indeed, the component elements of wealth itself also do) in the several successive stages of the social movement. The truth is that there are many different economic motors, altruistic as well as egoistic; and they cannot all be lumped together by such a coarse generalization. The *a priori* and purely deductive method cannot yield an explanation of the causes which regulate either the nature or the amount of wealth, nor of the varieties of distribution in different social systems, as, for example, in those of France and England. “The whole economy of every nation is the result of a long evolution in which there has been both continuity and change, and of which the economical side is only a particular aspect. And the laws of which it is the result must be sought in history and the general laws of society and social evolution.” The intellectual, moral, legal, political, and economic sides of social progress are indissolubly connected. Thus, juridical facts relating to property, occupation, and trade, thrown up by the social movement, are also economic facts. And, more generally,

“the economic condition of English” or any other “society at this day is the outcome of the entire movement which has evolved the political constitution, the structure of the family, the forms of religion, the learned professions, the arts and sciences, the state of agriculture, manufactures, and commerce.” To understand existing economic relations we must trace their historical evolution; and “the philosophical method of political economy must be one which expounds that evolution.” This essay was the most distinct challenge ever addressed to the ideas of the old school on method, and, though its conclusions have been protested against, the arguments on which they are founded have never been answered.

With respect to the dogmatic generalizations of the “orthodox” economics, Leslie thought some of them were false, and all of them required careful limitation. Early in his career he had shown the hollowness of the wage-fund theory, though he was not the first to repudiate it.¹ The doctrine of an average rate of wages and an average rate of profits he rejected except under the restrictions stated by Adam Smith, which imply a “small and stationary world of trade.” He thought the glib assumption of an average rate of wages, as well as of a wage-fund, had done much harm “by hiding the real rates of wages, the real causes which govern them, and the real sources from which wages proceed.” The facts, which he laboriously collected, he found to be everywhere against the theory. In every country there is really “a great number of rates; and the real problem is, What are the causes which produce these different rates?” As to profits, he denies that there are any means of knowing the gains and prospects of all the investments of capital, and declares it to be a mere fiction that any capitalist surveys the whole field. Bagehot, as we saw, gave up the doctrine of a national level of wages and profits except in the peculiar case of an industrial society of the contemporary English type; Leslie denies it even for such a society. With this doctrine, that of cost of production as determining price collapses, and the principle emerges that it is not cost of production, but demand and supply, on which domestic, no less than international, values depend,—though this formula will require much interpretation before it can be used safely and with advantage. Thus Leslie extends to the whole of the national industry the partial negation of the older dogma introduced by Cairnes through the idea of non-competing groups. He does not, of course, dispute the real operation of cost of production on price in the limited area within which rates of profit and wages are determinate and known; but he maintains that its action on the large scale is too remote and uncertain to justify our treating it as regulator of price. Now, if this be so, the entire edifice which Ricardo reared on the basis of the identity of cost of production and price, with its apparent but unreal simplicity, symmetry, and completeness, disappears; and the ground is cleared for the new structure which must take its place. Leslie predicts that, if political economy, under that name, does not bend itself to the task of rearing such a structure, the office will speedily be taken out of its hands by sociology.

Leslie was a successful student of several special economic subjects—of agricultural economy, of taxation, of the distribution of the precious metals and the history of prices, and, as has been indicated, of the movements of wages. But it is in relation to the method and fundamental doctrines of the science that he did the most important, because the most opportune and needful work. And, though his course was closed too early for the interests of knowledge, and much of what he produced was merely occasional and fragmen-

¹ That service was due to F. D. Longe (*Refutation of the Wage-Fund Theory of Modern Political Economy*, 1866). Leslie's treatment of the subject was contained in an article of *Fraser's Magazine* for July, 1868, reprinted as an appendix to his *Land-Systems and Industrial Economy of Ireland, England, and Continental Countries*, 1870.

tary, his services will be found to have been greater than those of many who have left behind them more systematic, elaborate, and pretentious writings.

One of the most original of the recent English writers on political economy was W. Stanley Jevons (1835-1882). The combination which he presented of a predilection and aptitude for exact statistical inquiry with sagacity and ingenuity in the interpretation of the results was such as might remind us of Petty. He tended strongly to bring economics into close relation with physical science. He made a marked impression on the public mind by his attempt to take stock of our resources in the article of coal. His idea of a relation between the recurrences of commercial crises and the period of the sun-spots gave evidence of a fertile and bold scientific imagination, though he cannot be said to have succeeded in establishing such a relation. He was author of an excellent treatise on *Money and the Mechanism of Exchange* (1875), and of various essays on currency and finance, which have been collected since his death, and contain vigorous discussions on subjects of this nature, as on bimetalism (with a decided tendency in favor of the single gold standard), and several valuable suggestions, as with respect to the most perfect system of currency, domestic and international, and in particular the extension of the paper currency in England to smaller amounts. He proposed in other writings (collected in *Methods of Social Reform*, 1883) a variety of measures, only partly economic in their character, directed especially to the elevation of the working classes, one of the most important being in relation to the conditions of the labor of married women in factories. This was one of several instances in which he repudiated the *laissez faire* principle, which indeed, in his book on *The State in Relation to Labor* (1882), he refuted in the clearest and most convincing way, without changing the position he had always maintained as an advocate of free trade. Towards the end of his career, which was prematurely terminated, he was more and more throwing off "the incubus of metaphysical ideas and expressions" which still impeded the recognition or confused the appreciation of social facts. He was, in his own words, ever more distinctly coming to the conclusion "that the only hope of attaining a true system of economics is to fling aside, once and forever, the mazy and preposterous assumptions of the Ricardian school." With respect to method, though he declares it to be his aim to "investigate inductively the intricate phenomena of trade and industry," his views had not perhaps assumed a definitive shape. The editor of some of his remains declines to undertake the determination of his exact position with respect to the historical school. The fullest indications we possess on that subject are to be found in a lecture of 1876, *On the Future of Political Economy*. He saw the importance and necessity in economics of historical investigation, a line of study which he himself was led by native bent to prosecute in some directions. But he scarcely apprehended the full meaning of what is called the historical method, which he erroneously contrasted with the "theoretical," and apparently supposed to be concerned with verifying and illustrating certain abstract doctrines resting on independent bases. Hence, whilst he declared himself in favor of "thorough reform and reconstruction," he sought to preserve the *a priori* mode of proceeding alongside of, and concurrently with, the historical. Political economy, in fact, he thought was breaking up and falling into several, probably into many, different branches of inquiry, prominent amongst which would be the "theory" as it had descended from his best predecessors, especially those of the French school, whilst another would be the "historical study," as it was followed in England by Jones, Rogers, and others, and as it had been proclaimed in general principle by his contemporary Cliffe Leslie. This was one of those eclectic views which

have no permanent validity, but are useful in facilitating a transition. The two methods will doubtless for a time coexist, but the historical will inevitably supplant its rival. What Jevons meant as the "theory" he wished to treat by mathematical methods (see his *Theory of Political Economy*, 1871; 2d ed., 1879). This project had, as we have seen, been entertained and partially carried into effect by others before him, though he unduly multiplies the number of such earlier essays when, for example, he mentions Ricardo and J. S. Mill as writing mathematically, because they sometimes illustrated the meaning of their propositions by dealing with definite arithmetical quantities. Such illustrations, of which a specimen is supplied by Mill's treatment of the subject of international trade, have really nothing to do with the use of mathematics as an instrument for economic research, or even for the co-ordination of economic truths. We have already, in speaking of Cournot, explained why, as it seems to us, the application of mathematics in the higher sense to economics must necessarily fail, and we do not think that it succeeded in Jevons's hands. His conception of "final utility" is ingenious, but we cannot regard it as either "positive" or fruitful. He offers as a valuable result of mathematical investigation the theorem that in every case of exchange the quantity of each of the articles concerned multiplied by its utility is the same. But what is the unit of utility? If we cannot look for something more tangible—not to say more serviceable—than this, there is not much encouragement to pursue such researches, which will in fact never be anything more than academic playthings, and which involve the very real evil of restoring the metaphysical entities previously discarded. The reputation of Jevons as an acute and vigorous thinker, inspired with noble popular sympathies, is sufficiently established. But the attempt to represent him, in spite of himself, as a follower and continuator of Ricardo, and as one of the principal authors of the development of economic theory (meaning by "theory" the old *a priori* doctrine) can only lower him in estimation by placing his services on grounds which will not bear criticism. His name will survive in connection, not with new theoretical constructions, but with his treatment of practical problems, his fresh and lively expositions, and, as we have shown, his energetic tendency to a renovation of economic method.

Arnold Toynbee (1852-1883), who left behind him a beautiful memory, filled as he was with the love of truth and an ardent and active zeal for the public good, was author of some fragmentary or unfinished pieces, which yet well deserve attention, both for their intrinsic merit and as indicating the present drift of all the highest natures, especially amongst our younger men, in the treatment of economic questions. He had a belief in the organizing power of democracy which it is not easy to share, and some strange ideas due to youthful enthusiasm, such as, for example, that Mazzini is "the true teacher of our age;" and he fluctuates considerably in his opinion of the Ricardian political economy, in one place declaring it to be a detected "intellectual imposture," whilst elsewhere, apparently under the influence of Bagehot, he speaks of it as having been in recent times "only corrected, re-stated, and put into the proper relation to the science of life," meaning apparently, by this last, general sociology. He saw, however, that our great help in the future must come, as much had already come, from the historical method, to which in his own researches he gave preponderant weight. Its true character, too, he understood better than many even of those who have commended it; for he perceived that it not only explains the action of special local or temporary conditions on economic phenomena, but seeks by comparing the stages of social development in different countries and times to "discover laws of universal application." If, as we

are told, there exists at Oxford a rising group of men who occupy a position in regard to economic thought substantially identical with that of Toynbee, the fact is one of good omen for the future of the science.

It is no part of our plan to pass judgment on the works of contemporary English authors—a judgment which could not in general be final, and which would be subject to the imputation of bias in a greater degree than estimates of living writers in foreign countries. But, for the information of the student, some opinions may be expressed which scarcely any competent person would dispute. The best brief exposition of political economy, substantially in accordance with Mill's treatise, is to be found in Fawcett's *Manual* (6th ed., 1884). But those who admit in part the claims of the new school will prefer Mr. and Mrs. Marshall's *Economics of Industry* (2d ed., 1881). Better, in some respects, than either is the *Political Economy* of the American professor, Francis A. Walker (1883), whose special treatises on *Money* and on the *Wages Question* may also be recommended. Other meritorious works are J. E. T. Rogers's *Manual of Political Economy*, 1870; John Macdonnell's *Survey of Political Economy*, 1871; and John L. Shadwell's *System of Political Economy*, 1877. Prof. W. E. Hearn's *Plutology* (1864) contains one of the ablest extant treatments of the subject of production. Mr. Goschen's is the best work on the foreign exchanges (10th ed., 1879). Mr. Macleod, though his general economic scheme has met with no acceptance, is recognized as supplying much that is useful on the subject of banking. Prof. Rogers's *Six Centuries of Work and Wages* (1884) is the most trustworthy book on the economic history of England during the period with which he deals. W. Cunningham's *Growth of English Industry and Commerce*, 1882, is instructive on the mercantile system. Dr. W. Neilson Hancock has shown in a multitude of papers a most extensive and accurate knowledge of the social economy of Ireland.

On American political economy the reader will consult with advantage an article in the *Fortnightly Review* for September, 1890, by Cliffe Leslie, which was written after the publication of his collected essays. We can only mention some of the best known works (besides those of F. A. Walker) produced in the United States. Amongst them are E. Peshine Smith's *Manual of Political Economy*, 1853; Francis Bowen's *American Political Economy*, 1870; Amasa Walker's *Science of Wealth*, 1867; A. L. Perry's *Elements of Political Economy*, 1866 (the two former writers are protectionist, the two latter free-traders; Perry is a disciple of Bastiat). The principal works on American economic history are those of A. S. Bolles, entitled *Industrial History of the United States*, and *Financial History of the United States*, 1774-1789, 1879.

We cannot here overlook a work like that of Mr. Sidgwick (1883), to which we have already referred on a special point. It is impossible not to respect and admire the conscientious and penetrating criticism which he applies to the *a priori* system of economics in its most mature form. But it is open to question whether the task was wisely undertaken. It cannot be permanently our business to go on amending and limiting the Ricardian doctrines, and asking by what special interpretations of phrases or additional qualifications they may still be admitted as having a certain value. The time for a new construction has arrived; and it is to this, or at least to the study of its conditions, that competent thinkers with the due scientific preparation should now devote themselves. It is to be feared that Mr. Sidgwick's treatise, instead of, as he hopes, "eliminating unnecessary controversy," will tend to revive the *stériles contestations* and *oiseuses disputes de mots*, which Comte censured in the earlier economists. It is interesting to observe that the part of the work which is, and has been recognized as, the most valuable is that in which, shaking off the fictions of the old school, he examines independently by the light of observation and analysis the question of the industrial action of Governments.

Let us briefly consider, in conclusion, by the light of the preceding historical survey, what appear to be the steps in the direction of a renovation of economic science which are now at once practicable and urgent.

I. Economic investigation has hitherto fallen for the most part into the hands of lawyers and men of letters, not into those of a genuinely scientific class. Nor have its cultivators in general had that sound preparation in the sciences of inorganic and vital nature which is necessary whether as supplying bases of doctrine or as furnishing lessons of method. Their education has usually been of a metaphysical kind.

Hence political economy has retained much of the form and spirit which belonged to it in the 17th and 18th centuries, instead of advancing with the times, and assuming a truly positive character. It is homogeneous with the school logic, with the abstract unhistorical jurisprudence, with the *a priori* ethics and politics, and other similar antiquated systems of thought; and it will be found that those who insist most strongly on the maintenance of its traditional character have derived their habitual mental pabulum from those regions of obsolete speculation. We can thus understand the attitude of true men of science towards this branch of study, which they regard with ill-disguised contempt, and to whose professors they either refuse or very reluctantly concede a place in their brotherhood.

The radical vice of this unscientific character of political economy seems to lie in the too individual and subjective aspect under which it has been treated. Wealth having been conceived as what satisfies desires, the definitely determinable qualities possessed by some objects of supplying physical energy, and improving the physiological constitution, are left out of account. Every thing is gauged by the standing of subjective notions and desires. All desires are viewed as equally legitimate, and all that satisfies our desires as equally wealth. Value being regarded as the result of a purely mental appreciation, the social value of things in the sense of their objective utility, which is often scientifically measurable, is passed over, and ratio of exchange is exclusively considered. The truth is, that at the bottom of all economic investigation must lie the idea of the destination of wealth for the maintenance and evolution of a society. And, if we overlook this, our economics will become a play of logic or a manual for the market, rather than a contribution to social science; whilst wearing an air of completeness, it will be in truth one-sided and superficial. Economic science is something far larger than the catallactics to which some have wished to reduce it. A special merit of the physiocrats seems to have lain in their vague perception of the close relation of their study to that of external nature; and, so far, we must recur to their point of view, basing our economics on physics and biology as developed in our own time. Further, the science must be cleared of all the theologico-metaphysical elements or tendencies which still encumber and deform it. Teleology and optimism on the one hand, and the jargon of "natural liberty" and "indefeasible rights" on the other, must be finally abandoned.

Nor can we assume as universal premises, from which economic truths can be deductively derived, the convenient formulas which have been habitually employed, such as that all men desire wealth and dislike exertion. These vague propositions, which profess to anticipate and supersede social experience, and which necessarily introduce the absolute where relativity should reign, must be laid aside. The laws of wealth (to reverse a phrase of Buckle's) must be inferred from the facts of wealth, not from the postulate of human selfishness. We must bend ourselves to a serious direct study of the way in which society has actually addressed itself and now addresses itself to its own conservation and evolution through the supply of its material wants. What organs it has developed for this purpose, how they operate, how they are affected by the medium in which they act and by the co-existent organs directed to other ends, how in their turn they react on those latter, how they and their functions are progressively modified in process of time—these problems, whether statical or dynamical, are all questions of fact, as capable of being studied through observation and history as the nature and progress of human language or religion, or any other group of social phenomena. Such study will of course require a continued "reflective analysis" of the results of observation; and, whilst eliminating all premature assumptions, we shall use

ascertained truths respecting human nature as guides in the inquiry and aids towards the interpretation of facts. And the employment of deliberately instituted hypotheses will be legitimate, but only as an occasional logical artifice.

II. Economics must be constantly regarded as forming only one department of the larger science of sociology, in vital connection with its other departments, and with the moral synthesis which is the crown of the whole intellectual system. We have already sufficiently explained the philosophical grounds for the conclusion that the economic phenomena of society cannot be isolated, except provisionally, from the rest,—that, in fact, all the primary social elements should be habitually regarded with respect to their mutual dependence and reciprocal actions. Especially must we keep in view the high moral issues to which the economic movement is subservient, and in the absence of which it could never in any great degree attract the interest or fix the attention either of eminent thinkers or of right-minded men. The individual point of view will have to be subordinated to the social; each agent will have to be regarded as an organ of the society to which he belongs and of the larger society of the race. The consideration of interests, as George Eliot has well said, must give place to that of functions. The old doctrine of right, which lay at the basis of the system of “natural liberty,” has done its temporary work; a doctrine of duty will have to be substituted; fixing on positive grounds the nature of the social co-operation of each class and each member of the community, and the rules which must regulate its just and beneficial exercise.

Turning now from the question of the theoretic constitution of economics, and viewing the science with respect to its influence on public policy, we need not at the present day waste words in repudiating the idea that “non-government” in the economic sphere is the normal order of things. The *laissez faire* doctrine, coming down to us from the system of natural liberty, was long the great watchword of economic orthodoxy, and it had a special acceptance and persistence in England, in consequence of the political struggle for the repeal of the corn laws, which made economic discussion in this country turn almost altogether on free trade—a state of things which was continued by the effort to procure a modification of the protective policy of foreign nations. But it has now for some time lost the sacrosanct character with which it was formerly invested. This is a result not so much of scientific thought as of the pressure of practical needs—a cause which has modified the successive forms of economic opinion more than theorists are willing to acknowledge. Social exigencies will force the hands of statesmen, whatever their attachment to abstract formulas; and politicians have practically turned their backs on *laissez faire*. The state has with excellent effect proceeded a considerable way in the direction of controlling, for ends of social equity or public utility, the operations of individual interest. The economists themselves have for the most part been converted on the question; amongst theorists Mr. Herbert Spencer finds himself almost a *vox clamantis in deserto* in protesting against what he calls the “new slavery” of Governmental interference. He will protest in vain, so far as he seeks to rehabilitate the old absolute doctrine of the economic passivity of the state. But it is certainly possible that even by virtue of the force of the reaction against that doctrine there may be an excessive or precipitate tendency in the opposite direction. With the course of production or exchange considered in itself there will probably be in England little disposition to meddle. But the dangers and inconveniences which arise from the unsettled condition of the world of labor will doubtless from time to time here, as elsewhere, prompt to premature attempts at regulation. Apart, however, from the removal of evils which threaten the public peace, and from temporary pallia-

tions to ease off social pressure, the right policy of the state in this sphere will for the present be one of abstinence. It is indeed certain that industrial society will not permanently remain without a systematic organization. The mere conflict of private interests will never produce a well-ordered commonwealth of labor. *Freiheit ist keine Lösung*. Freedom is for society, as for the individual, the necessary condition precedent of the solution of practical problems, both as allowing natural forces to develop themselves and as exhibiting their spontaneous tendencies; but it is not in itself the solution. Whilst, however, an organization of the industrial world may with certainty be expected to arise in process of time, it would be a great error to attempt to improvise one. We are now in a period of transition. Our ruling powers have still an equivocal character; they are not in real harmony with industrial life, and are in all respects imperfectly imbued with the modern spirit. Besides, the conditions of the new order are not yet sufficiently understood. The institutions of the future must be founded on sentiments and habits, and these must be the slow growth of thought and experience. The solution, indeed, must be at all times largely a moral one; it is the spiritual rather than the temporal power that is the natural agency for redressing or mitigating most of the evils associated with industrial life.¹ In fact, if there is a tendency—and we may admit that such a tendency is real or imminent—to push the state towards an extension of the normal limits of its action for the maintenance of social equity, this is doubtless in some measure due to the fact that the growing dissidence on religious questions in the most advanced communities has weakened the authority of the churches, and deprived their influence of social universality. What is now most urgent is not legislative interference on any large scale with the industrial relations, but the formation, in both the higher and lower regions of the industrial world, of profound convictions as to social duties, and some more effective mode than at present exists of diffusing, maintaining, and applying those convictions. This is a subject into which we cannot enter here. But it may at least be said that the only parties in contemporary public life which seem rightly to conceive or adequately to appreciate the necessities of the situation are those that aim, on the one hand, at the restoration of the old spiritual power, or, on the other, at the formation of a new one. And this leads to the conclusion that there is one sort of governmental interference which the advocates of *laissez faire* have not always discountenanced, and which yet, more than any other, tends to prevent the gradual and peaceful development of a new industrial and social system,—namely, the interference with spiritual liberty by setting up official types of philosophical doctrine, and imposing restrictions on the expression and discussion of opinions.

It will be seen that our principal conclusion respecting economic action harmonizes with that relating to the theoretic study of economic phenomena. For, as we held that the latter could not be successfully pursued except as a duly subordinated branch of the wider science of sociology, so in practical human affairs we believe that no partial synthesis is possible, but that an economic reorganization of society implies a universal renovation, intellectual and moral no less than material. The industrial reformation for which western Europe groans and travails, and the advent of which is indicated by so many symptoms (though it will come only as the fruit of faithful and sustained effort), will be no isolated fact, but will form one part of an applied art of life, modifying our whole environment, affecting our whole culture, and regulating our whole

¹ The neglect of this consideration, and the consequent undue exaltation of state action, which, though quite legitimate, is altogether insufficient, appears to us the principal danger to which the contemporary German school of economists is exposed.

conduct—in a word, consciously directing all our resources to the conservation and evolution of humanity.

The reader is referred for fuller information to the following works on the history of political economy, all of which have been more or less, and some very largely, used in the preparation of the foregoing outline.

GENERAL HISTORIES.—*Histoire de l'Economie Politique en Europe depuis les anciens jusqu'à nos jours*, by Jérôme Adolphe Blanqui (1837-38); of which there is an English translation by Emily J. Leonard (1880). *Histoire de l'Economie Politique*, by Alban de Villeneuve-Bargemont (Brussels, 1839; Paris, 1841); written from the Catholic point of view. *View of the Progress of Political Economy in Europe since the 16th Century*, by Travers Twiss, D.C.L. (1847). *Die geschichtliche Entwicklung der National-Ökonomik und ihrer Literatur*, by Julius Kautz (2d ed. 1860); a valuable work marked by philosophical breadth, and exhibiting the results of extensive research, but too declamatory in style. *Kritisch-Geschichte der Nationalökonomie und der Socialismus*, by Eugen K. Dühring (1871; 3d ed. 1879); characterized by its author's usual sagacity, but also by his usual perverseness and depreciation of meritorious writers in his own field. *Guida allo studio dell'Economia Politica*, by Luigi Cossa (1876 and 1878; Eng. trans. 1880). *Geschichte der Nationalökonomik*, by H. Eisenhart (1881); a vigorous and original sketch. And, lastly, a brief but excellent history by H. von Scheel in the *Handbuch der politischen Ökonomie* (really a great encyclopedia of economic knowledge in all its extent and applications), edited by Gustav Schönberg (1882). To these histories proper must be added *The Literature of Political Economy*, by J. R. McCulloch (1845), a book which might

with advantage be re-edited, supplemented where imperfect, and continued to our own time. Some of the biographical and critical notices by Eugène Daire and others in the *Collection des principaux Economistes* will also be found useful, as well as the articles in the *Dictionnaire de l'Economie Politique* of Coquelin and Guillaumin (1852-53), which is justly described by Jevons as "on the whole the best work of reference in the literature of the science."

SPECIAL HISTORIES.—*Italy*.—*Storia della Economia Pubblica in Italia, ossia Epilogo critico degli Economisti Italiani*, by Count Giuseppe Pecchio (1829), intended as an appendix to Baron Custodi's collection of the *Scrittori classici Italiani di Economia Politica*, 50 vols., comprising the writings of Italian economists from 1582 to 1804. There is a French translation of Pecchio's work by Leonard Gallois (1830). The book is not without value, though often superficial and rhetorical.

Spain.—*Storia della Economia Politica in España* (1863), by M. Colmeiro; rather a history of economy than of economics—of policies and institutions rather than of theories and literary works.

Germany.—*Geschichte der National-ökonomie in Deutschland* (1874), by Wilhelm Roscher; a vast repository of learning on its subject, with occasional side-glances at other economic literatures. *Die neuere National-ökonomie in ihren Hauptrichtungen*, by Moritz Meyer (3d ed., 1882); a useful handbook dealing almost exclusively with recent German speculation and policy.

England.—*Zur Geschichte der Englischen Volkswirtschaftslehre*, by W. Roscher (1851-52).

The reader is also advised to consult the articles of the present work which relate directly to the several principal writers on political economy. (J. K. I.)

POLK, JAMES KNOX (1795-1849), eleventh president of the United States of America, was of Scotch-Irish descent, his ancestors, whose name was Pollok, having emigrated from Ireland in the 18th century. He was the eldest of ten children, and was born 2d November, 1795, in Mecklenburg county, North Carolina, from which his father, who was a farmer, removed in 1806 to the valley of the Duck river, Tennessee.

At an early age he was placed in a merchant's office, but as he showed a disinclination for business his father at last permitted him to begin preparatory studies for the university. In 1815 he entered the university of North Carolina, where in 1818 he graduated with the highest honors. Called to the bar in 1820, he speedily made for himself a high reputation, and in 1823, he entered the State legislature. In August, 1825, he was chosen to represent his district in Congress, to which he was re-elected every succeeding two years until 1839. As a strong supporter of Democratic opinions he identified himself with every important discussion, and, though he was not a brilliant speaker, his solid abilities, extraordinary energy, and indomitable will soon gave him a place in the front rank of politicians. In 1835 he was chosen speaker of the House of Representatives, to which he was re-elected in 1837, and in 1839 he was elected governor of Tennessee. In 1844 he was the Democratic candidate for the presidency, and was chosen over Clay by a majority of sixty-five electoral votes. The election in great measure turned on the annexation of Texas, which was effected before his inauguration. One of the earliest questions with which his administration had to deal was the boundary of Oregon, which, although he had previously declared the title of the United States to Oregon to be "clear and undisputed," was finally fixed at the parallel of 49° instead of 54° 40'. Following the annexation of Texas came the Mexican war, resulting in the treaty of Guadalupe Hidalgo, 2d February, 1848, by which New Mexico and California were ceded to the United States. Other important measures of his administration were the admission of Iowa and Wisconsin to the Union, the adoption of a low tariff in 1846, the organization of the department of the interior, and the adoption of the method of collecting Government revenues by specie without the aid of the banks. Polk retired from office

4th March, 1849, and died in Nashville, 15th June of the same year.

Life of the Hon. James Knox Polk, with a Compendium of his Speeches, 1844; Chase, *History of the Polk Administration*, 1850.

POLLACK (*Gadus pollachius*), a species of cod-fish, abundant on rocky coasts of northern Europe, and extending as far south as the western parts of the Mediterranean, where, however, it is much scarcer and does not attain to the same size as in its real northern home. In Scotland and some parts of Ireland it is called *Lythe*. It is distinguished from other species of the genus *Gadus* by its long pointed snout, which is twice as long as the eye, with projecting lower jaw, and without a barbel at the chin. The three dorsal fins are composed of respectively 12, 18 or 20, and from 17 to 19 rays, and the two anal fins of 31 and 19 or 20. A black spot above the base of the pectoral fin is another distinguishing mark. Although pollack are well-flavored fish, and smaller individuals (from 12 to 16 inches) excellent eating, they do not form any considerable article of trade, and are not preserved, the majority being consumed by the captors. Specimens of twelve pounds are common, but the species is said to attain 24 pounds in weight.

POLLAN (*Coregonus pollan*), a species of the Salmonoid genus *Coregonus* which has been found in the large and deep loughs of Ireland only. A full account of the fish by its first describer, W. Thompson, may be found in his *Natural History of Ireland*, vol. iv. p. 168.

POLLIO, CAIUS ASINIUS (76 B.C.—4 A.D.), a Roman orator, poet and historian, who played a conspicuous part in the troubled history of his time, was born in 76 B.C. In his twenty-second year (54 B.C.) he impeached unsuccessfully C. Cato, who in his tribunate (56) had acted as the tool of the triumvirs. In the civil war between Cæsar and Pompey, Pollio sided with Cæsar, and after the successful campaigns against the remnants of the Pompeian party in Africa and Spain he was raised to the prætorship, and received the command of the war in Spain against Sextus Pompeius. At the time of Cæsar's assassination (March 15, 44) Pollio was in Spain. He was defeated by Sextus Pompeius and fled for his life. But by Lepidus's influence a peace was patched up and Sextus left Spain, while Pollio remained with three legions under him. During

the war between Mark Antony and the senate, Pollio, in a letter to Cicero, declared himself on the side of the senate, but found pretexts for waiting to cast in his lot with the victor. In fact no sooner had Octavian become reconciled to Antony and Lepidus, and compelled the senate to rescind the decrees against them, than Pollio joined Lepidus with two legions. Antony, Lepidus, and Octavian now formed the triumvirate (43), and Pollio was nominated consul for the year 40 B.C. Meantime he was entrusted by Antony with the administration of Gallia Transpadana, and in superintending the distribution of the Mantuan territory amongst the veterans he used his influence to save from confiscation the property of the poet Virgil. When L. Antonius, brother of Mark Antony, revolted against Octavian and was besieged in Perusia (41-40), he entreated Pollio to hasten to his relief. Pollio advanced hesitatingly, but was fain to take refuge in Ravenna when Octavian marched to meet him. After the fall of Perusia Octavian and Antony were reconciled for a time by the peace of Brundisium, which Pollio helped to negotiate. He was now consul (40); Virgil's famous fourth eclogue is addressed to him in his consulship. Next year Pollio was sent by Antony against the Parthini, an Illyrian people who adhered to Brutus. He was successful, took the town of Salonæ, and celebrated a triumph in the same year. The eighth eclogue of Virgil is addressed to Pollio while engaged in this campaign. From the spoils of the war he constructed the first public library at Rome.¹ Thenceforward Pollio withdrew from active life and devoted himself to literature. When Octavian invited him to join in the war against Antony which ended in the battle of Actium, Pollio declined on the score of his former friendship with Antony. He seems to have maintained to a certain degree an attitude of independence if not of opposition towards Augustus. He lived to a green old age, and died in his villa at Tusculum in 4 A.D.

Pollio was a distinguished orator; his speeches showed ingenuity and care, but were marred by an affected archaism which rendered them somewhat crabbed and harsh. He wrote tragedies also, which Virgil declared to be worthy of Sophocles, and a prose history of the civil wars of his time from the first triumvirate (60 B.C.) down to the death of Cicero (43 B.C.) or perhaps to the battle of Philippi (42 B.C.) or even later. This history, in the composition of which Pollio received assistance from the grammarian Ateius, was used as an authority by Plutarch and Appian. As a literary critic Pollio was very severe. He censured Sallust and Cicero and professed to detect in Livy's style certain provincialisms of his native Padua; he attacked the *Commentaries* of Julius Cæsar, accusing their author of carelessness and credulity if not of deliberate falsification. Horace addressed one of his odes (ii. 1) to Pollio on the subject of his history. Pollio was the first Roman author who recited his writings to an audience of his friends, a practice which afterwards grew very common at Rome. All his writings are lost except a few fragments of his speeches (collected by

Meyer, *Orat. Rom. Frag.*), and three letters addressed Cicero (*Cic., Ad Fam.*, x. 31-33).

PÖLLNITZ, KARL LUDWIG, FREIHERR VON (1692-1775), known as a writer of memoirs, was born on the 25th February, 1692. His father, G. Bernhard von Pöllnitz, was a major-general and minister of state in the electorate of Brandenburg. Pöllnitz was a man of restless and adventurous disposition, and after squandering his fortune travelled from court to court, his pleasant manners generally securing for him a kind reception. He was made reader to Frederick the Great, and afterwards the director of a theatre; but before accepting these appointments he had served as a soldier in Austria, the States of the Church, and Spain. He was repeatedly converted to Catholicism and re-converted to the Reformed faith; but he died a Catholic on the 23d June, 1775.

The most famous work attributed to him is *La Saxe galante*, which contains an account of the private life of Augustus of Saxony; but it has been doubted whether he was the author of this book. His contemporaries expressed much admiration for the lively style of his *Lettres et mémoires, avec nouveaux mémoires de sa vie et la relation de ses premières voyages*, and general interest was excited by his *État abrégé de la cour de Saxe sous le règne d'Auguste III., roi de Pologne*. He was probably the author of the *Histoire secrète de la duchesse d'Hanovre, épouse de George I., roi de la Grande-Bretagne*. After his death Brunn issued *Mémoires de Pöllnitz pour servir à l'histoire des quatre derniers souverains de la maison de Brandebourg, royale de Prusse*.

POLLOK, ROBERT (1798-1827), was the author of *The Course of Time*, a poem that has passed through many editions, and is still a favorite in serious households in Scotland. The son of a small farmer, he was born in 1798 at Moorhouse, in the parish of Eaglesham in Renfrewshire, was originally destined for the plough, but trained himself for the university, took his degree at Glasgow, and studied for the ministry of the United Secession Church. Along with the very general ambition to wag his head in a pulpit he had a specific literary ambition; he published *Tales of the Covenanters* while he was a divinity student, and planned and completed a poem on the spiritual life and destiny of man. This was the *Course of Time*. The unfortunate poet died within six months of its publication, at the age of twenty-nine. Excessive study had quickened a tendency to consumption. The poem was published in March, 1827, and at once became popular. It is written in blank verse, in ten books, in the poetic diction of the 18th century, but with abundance of enthusiasm, impassioned elevation of feeling, and copious force of words and images. The poet's view of life was strongly Calvinistic.

POLLOKSHAWs, a burgh of barony in Renfrewshire, Scotland, situated near the White Cart, on the Glasgow and Kilmarnock Railway, 2½ miles south by west of Glasgow, of which it is now reckoned a suburb, connected by tramway. The streets are irregular, but contain many good houses and shops. The principal buildings are the town hall, the mechanics' institute, and the public library and reading-room. The staple industries are cotton-spinning, hand and power-loom weaving of silk and cotton fabrics, dyeing, bleaching, and calico-printing. There are also paper works, potteries, and large engineering works. The town was created a burgh of barony by royal charter in 1813, and is governed by a provost, a baillie, and six councillors. Population in 1871, 8921; in 1881, 9363.

POLLUX. See **CASTOR AND POLLUX**.

POLLUX, JULIUS, of Naucratis in Egypt, a Greek sophist of the 2d century. His education was begun by his father, a man of literary culture, and was continued by one Hadrian, but he is said neither to have attained to the excellences nor fallen into the defects of his master. He taught at Athens, where, according to Philostratus, he was appointed to the professorship by the emperor Commodus on account of his melodious voice. He died at the age of fifty-eight, leaving a son behind him. Suidas gives a list

¹ The library was in the Atrium Libertatis, which was also erected by Pollio (*Isidor., Orig.*, vi. 5; *Sueton., Aug.*, 29; *Ovid, Trist.*, iii. 1, 71). The situation of this Atrium is uncertain. There was an older Atrium Libertatis near the Forum (*Cic. Ad Att.*, iv. 16, 8), but we are precluded from identifying it with that of Pollio by the language of Isidore and Suetonius, who imply that Pollio built a new Atrium. Perhaps Pollio's Atrium was connected with the temple of Liberty on the Aventine (*Livy*, xxiv. 16); this would be strongly confirmed by *Martial* (xii. 3, 6), if we could be sure that his "domus alta Remi" referred to the Aventine. *Mr. A. W. Verrall (Studies in Horace, p. 113)* has made it probable that *Dion Cassius* (xlix. 43) confused the Pollian with the Octavian library, and that accordingly 33 B.C. is the date of the dedication of the former library and not of the latter, which we know from *Plutarch (Marc.)*, 30, to have been dedicated not earlier than 23 B.C., the date of *Marcellus's* death. But *Mr. Verrall's* conjecture that "in the great reconstructions of Augustus" the Pollian library was absorbed in the Octavian seems negatived by *Ovid, Trist.*, iii. 1, 69-72, where "atria" certainly refers to the Pollian library, and "templa—vicino juncta theatro," probably refers to the Octavian library, which was in the Porticus Octavia, adjoining the twin temples of Jupiter and Juno, and close to the theatre of *Marcellus* (see *Burn, Rome and the Campagna*, p. 306 sq.). *Pliny (N. H., xxxvi. 24)* also refers to "Pollionis Asini monumenta" as being distinct from the Porticus Octavia. Moreover, there is no evidence that the two libraries were even near each other; if the Pollian was on the Aventine, they were separated by nearly the whole breadth of the city.

of his rhetorical works, none of which have survived. Philostratus (*Vit. Soph.*, ii. 12) recognizes his natural abilities, but speaks of his rhetoric in very moderate terms. He was ridiculed by Athenodorus, a contemporary teacher at Athens. It is a disputed point whether or not he is the butt of Lucian's scathing satire in the *Lexiphanes* and *Teacher of Rhetoric*. In the *Teacher of Rhetoric* Lucian lashes a vile and ignorant person who gains a reputation as an orator by sheer effrontery; the application of this—probably grossly exaggerated—portrait to Pollux, derives some color from the remark of Philostratus that the speeches of Pollux were more remarkable for boldness than art. The *Lexiphanes*, a satire upon the use of obscure and obsolete words, may conceivably have been directed against Pollux as the author of the *Onomasticon*. This work, which we still possess, is a Greek dictionary in ten books dedicated to Commodus, and arranged not alphabetically but according to subject matter. Though mainly a dictionary of synonyms and phrases, it supplies much rare and valuable information on many points of classical antiquity. It also contains numerous fragments of writers now lost.

The first book treats of the gods and their worship, kings, speed and slowness; dyeing, traders and artisans, fertility and barrenness, times and seasons, houses, ships, war, horses, agriculture, the parts of the plough and the wagon, bees. Book ii. treats of the ages and names of man, the parts of his body, his mind and soul, etc.; book iii. of kinship, marriage, citizenship, friendship, love, the relation of master and slave, mines, journeying, rivers, health, sickness, wealth, poverty, etc.; book iv. of the sciences and arts; book v. of the chase, animals, compound words, love and hate, blame, fair greetings, inscriptions, etc.; book vi. of feasts, wine, food, the talkative man, the flatterer, the passionate man, crimes, words compounded with *δυο*, *τρεῖς*, etc., gifts, laughter and weeping, etc.; book vii. of trades; book viii. of law and justice, magistrates, popular assemblies, etc.; book ix. of cities, coins, games, synonyms of likeness and unlikeness, etc., compounds in *σ*; book x. of vessels, instruments, and tools. The chief editions of Pollux's *Onomasticon* are those of Aldus (Venice, 1502); J. H. Lederlin and Tib. Hemsterhuis (Amsterdam, 1706); W. Dindorf (Leipzig, 1824), containing the notes of previous commentators; Im. Bekker (Berlin, 1846), containing the Greek text only.

POLO. This game, which is a species of "hockey on horseback," is of Eastern origin, and seems to have been a favorite pastime in Persia, Tartary, and the frontiers of India from prehistoric times. Every district has a different name for the game, and the rules under which it is played, although substantially identical, vary considerably on minor points. Thus in Little Tibet, Ladakh, and the adjacent districts the ground used is in the form of a parallelogram some hundred yards long with a goal at each end about 50 feet wide. Amongst the Manipuris, a semi-independent tribe on the northeast frontier of India, by whom the game is known as "kunjai," the ground is about 120 yards by 50 yards and the whole of each end forms a goal. In other places the goals are about 400 yards apart, and the ground is 120 yards wide at each end, increasing in width towards the centre.

In some of the early matches in the United Kingdom the ground was about 400 yards long and 200 yards wide, the width of the goal being from 30 to 35 yards. Under the present rules of the Hurlingham Club, which is now the principal authority on the game, it is provided that the goals shall be "not less than 250 yards apart and that each goal shall be 8 yards wide." The English name of the game is perhaps derived from "pulu," which is the Tibetan for a ball, and the pastime itself reached India from Persia through Afghanistan. It speedily gained favor with the officers of British cavalry regiments quartered in India, and was introduced into the United Kingdom in 1871 by the 10th Hussars. As far as can be ascertained the first match played on English soil took place at Aldershot in the spring of that year. This,

however, is not absolutely certain, as no records seem to have been preserved of the early contests.

Under the rules of the game as now played the opposing parties may consist of from three to six players a side, the number in all matches for cups or prizes being limited to four. Each of the players is mounted on a pony which must not exceed fourteen hands and which must be free from any vice. As the description of the game as "hockey on horseback" would imply, the object of the pastime is to force a ball by means of a stick, with which each player is furnished, through the goal of the opposing side. The size of the ball is 3 inches in diameter, and the sticks are 4 feet long with a cross piece at one end for the purpose of striking the ball. At the commencement of a game each side takes up its position behind the goal posts. A player on each side is appointed as goal-keeper. On a flag being dropped to notify the commencement of the game, the other players gallop towards the centre of the ground at full speed, their object being to reach the ball first and drive it in the direction of the opposite goal. When a ball is hit out of bounds it is thrown into play again by one of the umpires, of whom there is one appointed for each side before the commencement of a match. When a ball is hit beyond the goal without passing through it the side defending goal is entitled to a "hit off," which must be made from the goal line. It is allowable in the course of play to impede an adversary and hinder his stroke by hooking his stick, but this must not be done either under or over his pony. Whilst it is permissible for a player to interpose his pony before his antagonist so as to prevent the latter reaching the ball, it is expressly forbidden to cross another player in possession of the ball except at such a distance as to avoid all possibility of collision. Should a player break his stick or have it broken he must ride to the appointed place where the sticks are kept and take one, and on no account is one to be brought to him. If he drops his stick he must dismount and pick it up, and is not allowed to hit the ball whilst dismounted. If a player is in front of a player of his own side who hits the ball, and has not two—or in case of matches of four a side, one—of the opposing side between him and the hostile goal, and has not come through the "bully," he is "off side." He does not then come "on his side" until the ball has been hit or hit at by the opposing side, or until the player on his own side who made the hit passes him. As long as he is "off side" he may not in any way impede a player of the opposite side. In all matches the duration of play is 1 hour 10 minutes, with an interval of 5 minutes after each 20 minutes play.

Owing to the expense of maintaining a specially trained stud of ponies and a prepared ground for the pastime, the pursuit of the game of polo has always been confined to the wealthier classes in England. Its chief supporters are the younger members of the aristocracy and the officers of British cavalry regiments.

POLO, MARCO (c. 1254–1324), the Venetian, the most famous perhaps of all travellers. His history needs to be introduced by some account of the preceding generation of his family, and of the state of the world which rendered their and his extensive travels possible.

Under **CHINA**, in the introductory portion (vol. v. 545 sq.) we have briefly indicated the circumstances which in the last half of the 13th century and first half of the 14th threw Asia open to Western travellers to a degree unknown before and since. We first hear of the Polo family in the year 1260. The vast wave of Tartar conquest, set in motion by Jenghiz Khan, and continuing to advance for some years after his death, had swept away all political barriers from the China Sea to the western frontier of Russia. This huge extent of empire continued for a time to own a supreme chief in the Great Khan, the head of the house of Jenghiz, whose headquarters were in the Mongolian

steppe. Practically indeed the empire soon began to split up into several great monarchies under the descendants of his four sons, in order of age Juji, Jagatai, Oghotai, and Tuli. At the date we have named the supreme khanate had recently devolved upon Kublai, son of Tuli, and, after the founder, the ablest of his house. In the beginning of his reign Kublai carried out the transfer of the seat of rule from Karakorum on the northern verge of the Mongolian plains to the populous and civilized regions that had been conquered in the further East, a transfer which eventually converted the Tartar khan into a Chinese emperor.

Barka, the son of Juji, and the first of the house of Jenghiz to turn Moslem, reigned on the steppes of the Volga, where a standing camp, which eventually became a great city under the name of Sarai, had been established by his brother and predecessor Batu.

Hulagu, a young brother of Kublai, after taking Baghdad, and putting the caliph Mosta'sim to death, had become practically independent ruler of Persia, Babylonia, Mesopotamia, and Armenia, though he and his sons and his sons' sons continued to the end of the century to stamp the name of the Great Khan upon their coins, and to use the Chinese seal of state which he conferred.

The house of Jagatai had settled upon the pastures of the Ili and in the valley of the Jaxartes, and ruled also the populous cities of Samarkand and Bokhara.

Kaidu, grandson of Oghotai, who had been the immediate successor of Jenghiz, refused to recognize the transfer of supreme authority to his cousins, and through the long life of Kublai was a thorn in the side of the latter. His immediate authority was exercised in what we should now call Chinese Turkestan and Southern Central Siberia.

Northern China had been conquered by Jenghiz and his successors from the Tartar dynasty called *Kin* or "Golden," who had held it about a century. But southern China still remained in the hands of the native dynasty, whose capital was the great city now known as Hang-chow-foo. Their dominion was still substantially intact, but its subjugation was a task to which Kublai soon turned his attention, and it became the most prominent transaction of his reign.

In India the most powerful sovereign was the Turk sultan of Delhi; but, though both Sind and Bengal owned his supremacy, no part of peninsular India had yet been invaded. The Dravidian kingdoms of the south were still untouched by foreign conquest, and the accumulated gold of ages lay in their temples and treasuries an easy prey for the coming Moslem.

In the Indo-Chinese peninsula and the Eastern Islands a variety of kingdoms and dynasties were expanding and contracting, of which we have but dim and shifting glimpses. Their advance in wealth and art, far beyond what the present state of those regions would suggest, is attested by the vast and magnificent mediæval remains of architecture which are found at intervals over both the Indo-Chinese continental countries and the islands, as at Pagán in Burmah, at Ayutthia in Siam, at Ongkor and many other places in Camboja, at Borobodor and Branbanan in Java. All these remains are deeply marked by Hindu influence.

Venetian genealogies and traditions of uncertain value trace the Polo family to Sebennico in Dalmatia, and before the end of the 11th century names of its members are found in the Great Council of the republic. But the ascertained line of the traveller begins only with his grandfather. Andrea Polo of S. Felice was the father of three sons, Marco, Nicolo, and Maffeo, of whom the second was the father of the subject of this article. They were presumably "noble," *i. e.*, belonging to the families who had seats in the Great Council, and were enrolled in the *Libro d'Oro*; for we know that Marco the traveller is officially so styled (*nobilis vir*). The three brothers were engaged in commerce; the elder Marco, resident apparently

in Constantinople and in the Crimea, does not enter into the history.

In 1260 we find Nicolo and Maffeo at Constantinople. How long they had been absent from Venice we do not know. Nicolo was a married man, and had left his wife there. In the year named the two brothers went on a speculation to the Crimea, whence a succession of chances and openings carried them to the court of Barka Khan at Sarai, and further north, and eventually across the steppes to Bokhara. Here they fell in with certain envoys who had been on a mission from the Great Khan Kublai to his brother Hulagu in Persia, and by them were persuaded to make the journey to Cathay in their company. And thus the first European travellers of whom we have any knowledge reached China. Kublai, when they reached his court, was either at CAMBALUC (*q. v.*) *i. e.*, Peking, which he had just rebuilt on a vast scale, or at his beautiful summer seat at Shangtu in the country north of the great wall ("In Xanadu did Cubla Khan," etc.). It was the first time that the khan, a man full of energy and intelligence, had fallen in with European gentlemen. He was delighted with the Venetian brothers, listened eagerly to all that they had to tell of the Latin world, and decided to send them back as his envoys to the pope, with letters requesting the despatch of a large body of educated men to instruct his people in Christianity and in the liberal arts. The motive of the khan's request was doubtless much the same that some years back influenced the black king of Uganda on Lake Nyanza to make a similar request through the traveller Stanley. With Kublai, as with his predecessors, religion was chiefly a political engine. The khan must be obeyed; how man should worship God was no matter to him. But Kublai was the first of his house to rise above the essential barbarism of the Mongols, and he had been able enough to discern that the Christian Church could afford the aid he desired in taming his countrymen. It was only when Rome had failed lamentably to meet his advances that he fell back upon the lamas and their trumpery as, after a fashion, civilizing instruments.

The brothers arrived at Acre in April, 1269. They learned that Clement IV. had died the year before, and no new pope had yet been chosen. So they went home to Venice, where they found that Nicolo's wife was dead, but had left a son Marco, now a fine lad of fifteen.

The papal interregnum was the longest that had been known, at least since the dark ages. After the Polos had spent two years at home there was still no pope; and the brothers resolved on starting again for the East, taking young Mark with them. At Acre they took counsel with an eminent churchman, Tedaldo, archdeacon of Liège, and took from him letters to authenticate the causes that had hindered their mission. They had not yet left Ayas on the Cilician coast (then one of the chief points for the arrival and departure of the land-trade of Asia), when news overtook them that a pope had been elected in the person of their friend Archdeacon Tedaldo. They hastened back to Acre, and at last were able to execute Kublai's commission and to obtain a papal reply. But, instead of the hundred teachers asked for by the Great Khan, the new pope (styled Gregory X.) could supply but two Dominicans; and these lost heart and turned back, when they had barely taken the first step of their journey.

The second start from Acre must have taken place about November, 1271; and from a careful consideration of the indications and succession of chapters in Marco Polo's book, it would seem that the party proceeded from Ayas to Sivas, and then by Mardin, Mosul, and Baghdad to Hormuz at the mouth of the Persian Gulf (see ORMUS), with the purpose of going on to China by sea; but that, some obstacle having interfered which compelled them to abandon this plan, they returned northward through Persia. Traversing

Kerman and Khorasan they went on to Balkh and Badakhshan, in which last country—an Oriental Switzerland, as it has been called—they were long detained by the illness of young Marco. In a passage touching on the charming climate of the hills of Badakhshan, Marco breaks into an enthusiasm which he rarely betrays, but which is easily understood by those who have known what it is, with fever in the blood, to escape to the exhilarating air and fragrant pine-groves of the Himálaya. They then ascended the upper Oxus through Wakhán to the plateau of Pamír (a name first heard in Marco's book). Those regions, so attractive to geographers, were never described again by any European traveller till the spirited expedition in 1838 of that excellent officer the late Lieutenant John Wood of the Indian navy, whose narrative abounds in the happiest incidental illustration of Marco Polo's chapters. Crossing the Pamír highlands, the travellers descended upon Kashgar, whence they proceeded by Yarkand to Khotan. These are regions which remained almost absolutely closed to our knowledge till within the last twenty years, when the temporary overthrow of the Chinese power, and the enterprise of travellers like the late Mr. Johnson and Mr. Robert Shaw, followed by the missions of Sir Douglas Forsyth and his companions, and of Mr. Ney Elias, again made them known.

From Khotan they passed on to the vicinity of Lake Lop (or Lob), reached still more recently, for the first time since Marco Polo's journey, by the indefatigable Russian officer Prejevalsky, in 1871. Thence the great desert of Gobi was crossed to Tangut, as the region at the extreme northwest of China, both within and without the Wall, was then called.

In his account of the passage of the Gobi, or desert of Lop, as he calls it, Polo gives some description of the terrors with which the suggestions of solitude and desolation have peopled such tracts in most parts of the world, a description which reproduces with singular identity that of the Chinese pilgrim HWEN T'SANG (*q.v.*), in passing the same desert in the contrary direction six hundred years before.

The Venetians, in their further journey, were met and welcomed by the Great Khan's people, and at last reached his presence at Shangtu, in the spring of 1275. Kublai received them with great cordiality, and took kindly to young Mark, by this time about one and twenty years of age. The "young bachelor," as the book calls him, applied himself diligently to the acquisition of the divers languages and written characters chiefly in use among the multifarious nationalities included in the khan's court and administration; and Kublai, seeing that he was both clever and discreet, soon began to employ him in the public service. M. Pauthier, his most recent French editor, has found in the Chinese annals a record that in the year 1277 a certain Polo was nominated as a second-class commissioner or agent attached to the imperial council, a passage which we may without scruple apply to the young Venetian.

His first public mission was one which carried him through the provinces of Shansi, Shensi, and Szechuen, and the wild country on the coast of Tibet, to the remote province of Yunnan, called by the Mongols *Kardjang*, and into northern Burmah (Mien). Marco, during his stay at court, had observed the khan's delight in hearing of strange countries, of their manners, marvels, and oddities, and had heard his frank expressions of disgust at the stupidity of envoys and commissioners who could tell of nothing but their official business. And he took care to store his memory or his note-book with all curious facts that were likely to interest Kublai, and these, on his return to court, he related with vivacity. This first journey led him through a country which twenty years ago was an almost absolute *terra incognita*,—though within that time we have learned much regarding it through the journeys of Cooper, Garnier, Richthofen, Gill, Baber,

and others. In this region there existed, and there still exists, in the deep valleys of the great rivers, and in the alpine regions which border them, a vast ethnological garden, as it were, of tribes of very various origin, and in every stage of semi-civilization or barbarism; and these afforded many strange products and eccentric traits of manners to entertain the emperor.

Marco rose rapidly in favor, and was often again employed on distant missions, as well as in domestic administration; but we are able to gather but few details of his employment. At one time we know that he held for three years the government of the great city of Yangchow; on another occasion we find him visiting Karakorum on the north of the Gobi, the former residence of the Great Khans; again in Champa, or southern Cochin-China; and, once more, on a mission to the southern states of India. We are not informed whether his father and uncle shared in such employments, though they are specially mentioned as having rendered material service to the khan, in forwarding the capture of the city of Siang-yang-foo (on the Han river) during the war against southern China, by the construction of powerful artillery engines—a story, however, perplexed by chronological difficulties, which here we must pass over.

In any case the elder Polos were gathering wealth, which they longed to carry back to their home in the lagoons, and after their long exile they began to dread what might follow old Kublai's death. The khan, however, was deaf to all suggestions of departure; and but for a happy chance we should have lost our mediæval Herodotus.

Arghun, khan of Persia, the grandson of Kublai's brother Hulagu, lost in 1286 his favorite wife, Bolgana (*Bulughân* or "Sable") by name. Her dying injunction was that her place should be filled only by a lady of her own Mongol tribe. Ambassadors were despatched to the court of Khánbáligh to obtain such a bride. The message was courteously received, and the choice fell on the lady Cocachin (*Kukáchim*), a maiden of seventeen, "moult bele dame et avenant." The overland road from Peking to Tabriz was not only of portentous length for so delicate a charge, but was then imperilled by war; so the envoys of Arghun proposed to return by sea. Having made acquaintance with the Venetians, and eager to profit by their experience, especially by that of Marco, who had just returned from his mission to India, they begged the khan as a favor to send the Franks in their company. He consented with reluctance, but fitted out the party nobly for the voyage, charging them with friendly messages to the potentates of Christendom, including the king of England. They appear to have sailed from the port of Chwan-chow (or CHINCHOW, *q.v.*) in Fuhkien, which was then the great haven of foreign trade, and was known to Western strangers as Zaitún, in the beginning of 1292. The voyage was an ill-starred one, involving long detention on the coast of Sumatra, and in the south of India; and two years or more passed before they arrived at their destination in Persia. Two out of the three envoys, and a vast proportion of their suite perished by the way; but the three hardier Venetians survived all perils, and so did the young lady, who had come to look on them with filial regard. It proved that Arghun Khan had been dead even before they quitted China; his brother reigned in his stead; and his son Ghazan succeeded to the lady's hand. She took leave of the kindly Venetians, not without tears; they went on to Tabriz, and after a long delay there departed for Venice, which they seem to have reached about the end of 1295.

The first biographer of Marco Polo was the famous geographical collector John Baptist Ramusio, who wrote more than two centuries after the traveller's death. Facts and dates sometimes contradict his statements, but his story is told with great life and picturesqueness, and we need not hesitate to accept, at

least as a genuine tradition, a romantic story, too long for repetition here, of the arrival of the Polos at their family mansion in the parish of St. John Chrysostom, of their appearance at its door in worn and outlandish garb, of the scornful denial of their identity, and of the shrewd stratagem by which they secured acknowledgment from the society of Venice.

Some years pass ere we hear more of Marco Polo; and it is then in a militant capacity.

Jealousies, always too characteristic of Italian communities, were in the case of Venice and Genoa sharpened by direct commercial rivalry, and had been growing in bitterness throughout the 13th century. In 1298 the Genoese made preparations on a great scale to strike a blow at their rivals on their own ground, and a powerful fleet of galleys, under Lamba Doria as admiral, made straight for the Adriatic. Venice, on hearing of the Genoese armament, hastily equipped a fleet still more numerous, and placed it under the command of Andrea Dandolo. The crew of a Venetian galley at this time amounted, all told, to 250 men, under a *comito* or master, but besides this officer each galley carried a *sopracomito* or gentleman commander, who was usually a noble. On one of the galleys of Dandolo's fleet went Marco Polo in this last capacity.

The hostile fleets met before the island of Curzola on the 6th September, and engaged next morning. The battle ended in a complete victory to Genoa, the details of which may still be read, inscribed on the façade of the church of St. Matthew in that city. Sixty-six Venetian galleys were burnt in the Bay of Curzola, and eighteen were carried to Genoa, with 7000 prisoners, one of whom was Marco Polo. The captivity was of less than a year's duration; for by the mediation of Milan peace was made, on honorable terms for both republics, by July, 1299; and Marco Polo was probably restored to his family during that or the following month.

But his captivity was memorable as being the means of bringing about the record of his remarkable experiences in the East. Up to this time he had doubtless often related his stories of Cathay among his friends; and from these stories indeed, and the frequent employment in them (as it would seem) of a numerical expression unfamiliar in those days, he had acquired the nickname of *Marco Million*. Yet it would seem that he had committed nothing to writing.

The narratives not only of Marco Polo but of several other famous mediæval travellers (*e. g.*, Ibn Batuta, Friar Odoric, Nicolo Conti) seem to have been extorted from them by a kind of pressure, and committed to paper by other hands. This indicates indeed how little the literary ambition which besets so many modern travellers weighed with the class in those days. It is also perhaps an example of that intense dislike to the use of pen and ink which still prevails among ordinary respectable folk on the shores of the Mediterranean.

But, in the prison of Genoa, Marco Polo fell in with a certain person of writing propensities, Rusticiano or Rustichello of Pisa, who also was a captive of the Genoese. His name is known otherwise to literary antiquaries as that of a respectable kind of literary hack, who abridged and recast several of the French romances of the Arthurian cycle which were then in fashion. He it was, apparently, who persuaded Marco Polo to defer no longer the committal to paper of his wonderful experiences. In any case it was he who wrote down these experiences at Marco's dictation; and he is the man, therefore, to whom we owe the existence of this record, and possibly the preservation even of the traveller's name and memory.

We learn but little of Marco Polo's personal or family history after this captivity; but we know that at his death he left a wife, Donata by name (perhaps of the family of Loredano, but this is uncertain), and three daughters, Rantina and Bellela married, the

former to Marco Bragadino, and Moreta then a spinster, but married at a later date to Ranuzzo Dolfino. One last glimpse of the traveller is gathered from his will, which is treasured in the library of St. Mark's. On the 9th January, 1324, the traveller, now in his seventieth year, and sinking day by day under bodily infirmity, sent for a neighboring priest and notary to make his testament. We do not know the exact time of his death, but it fell almost certainly within the year 1324, for we know from a scanty series of documents, commencing in June, 1325, that he had at the latter date been some time dead. He was buried in accordance with his will, in the church of St. Lorenzo, where the family burying-place was marked by a sarcophagus, erected by his filial care for his father Nicolo, which existed till near the end of the 16th century. On the renewal of the church in 1592 this seems to have been cast aside and lost.

The copious archives of Venice have yielded up a few traces of our traveller. Besides his own will just alluded to, there are in the library the wills of his uncle Marco and of his younger brother Maffeo; a few legal documents connected with the house property in St. John Chrysostom, and other papers of similar character; and two or three entries in the record of the *Maggior Consiglio*. We have mentioned the sobriquet of Marco Million which he got from his young townsmen. Ramusio tells us that he had himself noted the use of this name in the public books of the commonwealth, and this statement has been verified of late years in one of those entries in the books of the Great Council (dated 10th April, 1305), which records as one of the securities in a certain case the "Nobilis vir *Marchus Paulo MILION*." It is alleged that long after the traveller's death there was always in the Venetian masques one individual who assumed the character of Marco Million, and told Munchausen-like stories to divert the vulgar. Such, if this be true, was the honor of our great man in his own country. One curious parchment among those preserved is the record of the judgment of the court of requests (*Curia Petitionum*) upon a suit brought by the "*Nobilis Vir Marcus Polo*" against Paulo Girardo, who had been an agent of his, to recover the value of a certain quantity of musk for which Girardo had not accounted. Another curious document brought to light within the last few years is a catalogue of certain curiosities and valuables which were collected in the house of the unhappy Marino Faliero, and this catalogue comprises several objects that Marco Polo had given to one of the Faliero family. Among these are two which would have been of matchless interest had they survived, viz.—"*Unum anulum con inscriptione que dicit Cuibile Can Marco Polo, et unum torques cum multis animalibus Tartarorum sculptis que res donum dedit predictus Marcus quidam (euidam) Faletorum.*"

The most tangible record of Polo's memory in Venice is a portion of the Ca' Polo—the mansion (there is every reason to believe) where the three travellers, after their absence of a quarter century, were denied entrance. The court in which it stands was known in Ramusio's time as the *Corte del Million*, and now is called Corte Sabbionera. That which remains of the ancient edifice is a passage with a decorated archway of Italo-Byzantine character pertaining to the 13th century. With this exception, what was probably the actual site of the mansion is now occupied by the Malibran theatre.

No genuine portrait of Marco Polo exists. There is a medallion portrait on the wall of the Sala dello Sudo in the ducal palace, which has become a kind of type; but it is a work of imagination no older than 1761. The oldest professed portrait is one in the gallery of Monsignor Badia at Rome, which is inscribed *Marcus Polus Venetus Totius Orbis et Indie Peregrator Primus*. It is a good picture, but evidently of the 16th century at earliest, and the figure is of the character of that time. The Europeans at Canton have

attached the name of Marco Polo to a figure in a Buddhist temple there containing a gallery of "Arhans" or Buddhist saints, and popularly known as the "temple of the five hundred gods." There is a copy of this at Venice, which the Venetian municipality obtained on the occasion of the Geographical Congress there in 1881. But the whole notion was a groundless fancy.

The book indited by Rusticiano the Pisan, which has preserved Marco Polo's fame, consists essentially of two parts. The first, or prologue, as it is termed, is the only part unfortunately which consists of actual personal narrative. It relates in a most interesting, though too brief, fashion the circumstances which led the two elder Polos to the khan's court, with those of their second journey accompanied by Marco, and of the return to the West by the Indian seas and Persia. The second and staple part of the book consists of a long series of chapters of very unequal length and unsystematic structure, descriptive of the different states and provinces of Asia, with occasional notices of their sights and products, of curious manners and remarkable events, and especially regarding the emperor Kublai, his court, wars, and administration. A series of chapters near the close treats in a wordy and monotonous manner of sundry wars that took place between various branches of the house of Jenghiz in the latter half of the 13th century. This last series is either omitted or greatly curtailed in all the MS. copies and versions except one.

It was long a doubtful question in what language the work was originally written. That this had been some dialect of Italian was a natural presumption, and a contemporary statement could be alleged in its favor. But there is now no doubt that the original was French. This was first indicated by Count Baldelli-Boni, who published an elaborate edition of two of the Italian texts at Florence in 1827, and who found in the oldest of these indisputable signs that it was a translation from the French. The argument has since been followed up by others; and a manuscript in rude and peculiar French, belonging to the National Library of Paris, which was printed by the Société de Géographie in 1824, has been demonstrated (as we need not hesitate to say) to be either the original or a very close transcript of the original dictation. A variety of its characteristics are strikingly indicative of the unrevised product of dictation, and are such as would necessarily have disappeared either in a translation or in a revised copy. Many illustrations could be adduced of the fact that the use of French was not a circumstance of a surprising or unusual nature; for the language had at that time, in some points of view, even a wider diffusion than at present, and examples of its literary employment by writers who were not Frenchmen are very numerous. It is superfluous to allege instances here, when we observe that Rusticiano himself, the scribe of the narrative, was a compiler of French romances.

Some eighty MSS. of the book are known, and their texts exhibit considerable differences. These fall under four principal types. Of these type i. is found completely only in that old French codex which has been mentioned. Type ii. is shown by several valuable MSS. in purer French, the best of which formed the basis of the edition prepared by the late M. Pauthier in 1865. It exhibits a text pruned and revised from the rude original, but without any exactness, though perhaps under some general direction by Marco Polo himself, for an inscription prefixed to one of the MSS. records the presentation of a copy by the traveller himself to the Seigneur Thibault de Cepoy, a distinguished Frenchman known to history, at Venice in the year 1306. Type iii. is that of a Latin version prepared in Marco Polo's lifetime, though without any sign of his cognizance, by Francesco Pipino, a Dominican of Bologna, and translated from an Italian copy. In this, condensation and curtailment are carried a good deal further than in type ii. Some of the forms under which this type appears curiously illustrate the effects of absence of effective publication, not only before the invention of the press, but in its early days. Thus the Latin version published by Grynæus at Basel in the *Novus Orbis* (1532) is different in its language from Pipino's, and yet is clearly traceable to that as its foundation. In fact it is a retranslation into Latin from some version of Pipino (Marsden thinks the Portuguese printed one of 1502). It introduces also changes of its own, and is quite worthless as a text; and it is curious that Andreas Müller, who in the 17th century took much trouble with editing Polo according to his lights, should have unfortunately chosen as his text this fifth-hand version. It may be added that the French editions published in the middle of the 16th century were translations from Grynæus's Latin. Hence they complete this curious and vicious circle of translation—French,

Italian, Pipino's Latin, Portuguese, Grynæus's Latin, French.

The fourth type of text deviates largely from those already mentioned; its history and true character are involved in obscurity. It is only represented by the Italian version prepared for the press by G. B. Ramusio, with most interesting preliminary dissertations, and published at Venice two years after his death, in the second volume of the *Navigazioni e Viaggi*. Its peculiarities are great. Ramusio seems to imply that he made some use of Pipino's Latin, and various passages confirm this. But many new circumstances, and anecdotes occurring in no other copy, are introduced; many names assume a new shape; the whole style is more copious and literary in character than that of any other version. Whilst a few of the changes and interpolations seem to carry us further from the truth, others contain facts of Asiatic nature or history, as well as of Polo's alleged experiences, which it is extremely difficult to ascribe to any hand but the traveller's own.

We recognize to a certain extent tampering with the text, as in cases where the proper names used by Polo have been identified, and more modern forms substituted. In some other cases the editorial spirit has been more meddlesome and has gone astray. Thus the age of young Marco has been altered to correspond with a date which is itself erroneous. Ormus is described as an island, contrary to the old texts, and to the facts of its position in Polo's time. In speaking of the oil-springs of Caucasus the phrase "camel-loads" has been substituted for "ship-loads," in ignorance that the site was Baku on the Caspian.

But on the other hand there are a number of new circumstances certainly genuine, which can hardly be ascribed to any one but Polo himself. We will quote one only. This is the account which Ramusio's version gives of the oppressions exercised by Kublai's Mohammedan minister Ahmed, telling how the Cathayans rose against him and murdered him, with the addition that Messer Marco was on the spot when all this happened. Not only is the whole story in substantial accordance with the Chinese annals, even to the name of the chief conspirator (*Vanchu* in Ramusio, *Wang-chu* in the Chinese records), but the annals also tell of the courageous frankness of "Polo, assessor of the privy council," in opening Kublai's eyes to the iniquities of his agent.

To sum up, we can hardly doubt that we have, imbedded in the text of this most interesting edition of Ramusio's, the supplementary recollections of the traveller, noted down at a later period of his life, but perplexed by translation and retranslation and editorial mistakes. The most important desideratum still remaining in reference to Polo's book is the recovery of the original from which Ramusio derived the passages peculiar to his edition.

That Marco Polo has been so universally recognized as the prince of mediæval travellers is due rather to the width of his experience, the vast compass of his journeys, and the romantic nature of his personal history than to transcendent superiority of character or capacity. Enthusiastic biographers, beginning with Ramusio, have placed him on the same platform with Columbus. But he has left no trace of the genius and lofty enthusiasm, the ardent and justified previsions, which mark the great admiral as one of the lights of the human race. It is a juster praise that the spur which his book eventually gave to geographical studies, and the beacons which it hung out at the eastern extremities of the earth, helped to guide the aims, though hardly to kindle the fire of the greater son of the rival republic. His work was at least a link in the providential chain which at last dragged the New World to light.

But Polo also was the first traveller to trace a route across the whole longitude of Asia, naming and describing kingdom after kingdom, which he had seen with his own eyes; the first to speak of the new and brilliant court which had been established at Peking; the first to reveal China in all its wealth and vastness, and to tell us of the nations on its borders, with all their eccentricities of manners and worship; the first to tell more of Tibet than its name, to speak of Burmah, of Laos, of Siam, of Cochin-China, of Japan, of Java, of Sumatra, and of other islands of the Great Archipelago, that museum of beauty and marvels, of Nicobar and Andaman Islands with their naked savages, of Ceylon and its sacred peak, of India, not as a dream-land of fables, but as a country seen and partially explored; the first in mediæval times to give any distinct account of the secluded Christian empire of Abyssinia, and of the semi-Christian island of Socotra, and to speak, however dimly, of Zanzibar, and of the vast and distant Madagascar; whilst he carries us also to the remotely opposite region of Siberia and the Arctic shores, to speak of dog-sledges, white bears, and reindeer-riding Tunguses. That all this rich catalogue of discoveries (as they may fitly be called) should belong to the revelation of one man and one

book is ample ground enough to justify a very high place in the roll of fame.

Indeed it is remarkable in how large a proportion of the Old World modern travellers and explorers have been but developing what Marco Polo indicated in outline,—it might be said, without serious hyperbole, only travelling in his footsteps, most certainly illustrating his geographical notices. At the moment when these lines are written a British mission is starting to survey for political reasons a tract upon the Oxus; Marco Polo traversed this tract. For twenty years Russian and English explorers have been trying to solve the problem of the Pamir watershed; Marco Polo explored it. Till within the last quarter century the cities of eastern Turkestan, such as Kashgar, Yarkand, and Khotan, were known only from the compilation of Oriental fragments; Marco had visited them all. Within a shorter period dense darkness hung over the tracts between western China and Upper Burmah; these also had been traversed by Marco Polo. France is now scattering the brands of war in Tongking, in Fuhkien, and in Madagascar; all these were within Marco's Polo's knowledge and find mention in his book. And how vast an area has he described from personal knowledge which remains outside of the fields that we have indicated! Readers of the book would welcome a little more of egotistical detail. Impersonality is carried to excess; and we are often driven to discern only by indirect and doubtful induction whether he is speaking of places from personal knowledge or from hearsay. In truth, though there are delightful exceptions, and though nearly every part of the book suggests interesting questions, a desperate meagreness and baldness does affect considerable parts of the narrative. In fact his work reminds us sometimes of his own description of Khorasan—"On chevauche par beaus plains et belles costieres, là ou il a moult beaus herbages et bonne pasture et fraises assez . . . et aucune fois y treuve l'en un desert de soixante milles ou de mains, esquel desers ne treuve l'en point d'eau; mais la convient porter o lui!"

The diffusion of the book was hardly so rapid as has been sometimes alleged. It is true that we know from Gilles Mallet's catalogue of the books collected in the Louvre by Charles V., dating c. 1370-75, that no less than five copies of Marco Polo's work were then in the collection; but on the other hand the number spread over Europe of MSS. and early printed editions of Mandeville, with his lying wonders, indicates a much greater popularity. Dante, who lived twenty-three years after the book was dictated, and who touches so many things in the seen and unseen worlds, never alludes to Polo, nor, we believe, to anything that can be connected with him, nor can any trace of Polo be discovered in the book of his contemporary Marino Sanudo the elder, though this worthy is well acquainted with the work, later by some years, of Hayton the Armenian, and though many of the subjects on which he writes in his own book (*De Secretis Fidelium Crucis*) challenge a reference to Polo's experiences. Perhaps indeed the most notable circumstance bearing in the same direction is the fact that the author of Mandeville, whoever he really was, and who plundered right and left, never plunders Polo, a thing only to be accounted for by his being ignorant of Polo's existence. The only literary work we know of belonging to the 14th century which shows a thorough acquaintance with Polo's book is the poetical romance of *Baudouin de Sebourg*, which borrows themes from it largely.

Marco Polo contributed so vast an amount of new facts to the knowledge of the earth's surface, that one might have expected his book to have a sudden effect upon geography. But no such result occurred for a long time. Doubtless several causes contributed to this, of which the unreal character attributed to the book as a collection of romantic marvels rather than of geographical and historical facts, may have been one,—a view that the diffusion of Mandeville's fictions, far outdoing Polo's facts in marvel, perhaps tended to corroborate, whilst supplanting the latter in popularity. But the essential causes were the imperfect nature of publication; the traditional character of the prevailing geography, which hampered the propagation of true statements; and the entire absence of scientific principle in what did pass for geography, so that there was no organ competent to the assimilation of so huge a mass of new knowledge.

The late Sir Francis Palgrave wrote a book called *The Merchant and the Friar*, in which it is feigned that Marco Polo comes to England, and becomes acquainted with Roger Bacon. Had Roger Bacon indeed known either the traveller or his book, we cannot doubt, from the good use he makes, in his *Opus Majus*, of William of Rubruk, that he would have turned the facts to good account.

1 Printed by Bongars in the collection called *Gesta dei per Francos*, 1611.

But the world with which the map makers of the 13th and 14th centuries dealt was, in its outline, that handed down by traditions of the craft, as sanctioned by some fathers of the church, such as Orosius and Isidore, and sprinkled with a combination of classical and mediæval legends. Almost universally the earth's surface fills a circular disk, rounded by the ocean,—a fashion that already was ridiculed by Herodotus (iv. 36), as it was in a later generation by Aristotle (*Meteorol.*, ii. 5). This was the most persistent and the most obstructive dogma of the false geography. The central point of the circle is occupied by Jerusalem, because it was found written in Ezekiel: "Hæc dicit Dominus Deus, Ista est Jerusalem, in medio gentium posui eam, et in circuitu ejus terras,"—supposed to be corroborated by the Psalmist's expression, regarded as prophetic of our Lord's passion—"Deus autem Rex noster ante sæcula operatus est salutem in medio terræ" (Ps. lxxiv. 12). Paradise occupied the extreme east, because it was found in Genesis that the Lord planted a garden eastward in Eden. Gog and Magog were set in the far north or northeast because it was again said in Ezekiel: "Ecce ego super te Gog principem capitis Mosoch et Thubal . . . et ascendere te faciam de lateribus aquilonis." This last legend of Gog and Magog, shut up by a mountain-barrier, plays a prominent part in the romantic history of Alexander, which had such enormous currency in those ages, and attracted especial attention in the 13th century, owing to the general identification of the Tartar hordes with those impure nations whom the hero had shut up. It is not wonderful that the Tartar irruption into the West, heard of at first with as much astonishment as it would produce now, was connected with this old belief.

The loose and scanty nomenclature of the cosmography was mainly borrowed from Pliny and Mela, through such fathers as we have named; whilst vacant spaces were occupied by Amazons, Arimasians, and the realm of Prester John. A favorite representation of the inhabited earth was a great T within an O (see MAP).

Such schemes of the world had no place for the new knowledge. The first genuine attempt at a geographical compilation absolutely free from the traditional *idola* seems to be that in the *Portulano Mediceo* at Florence. In this, some slight use seems to be made of Polo. But a far more important work is one of the next generation, the celebrated Catalan map of 1375 in the Paris library. This also is an honest endeavor on a large scale to represent the known world on the basis of collected facts, casting aside all theories, pseudo-scientific and pseudo-theological; and a very remarkable work it is. In this work Marco Polo's influence on maps is perhaps seen to the greatest advantage. As regards Central and Further Asia, and partially as regards India, his book is the basis of the map. His names are often much perverted, and it is not always easy to understand the view that the compiler took of his itineraries. Still we have Cathay admirably placed in the true position of China, as a great empire filling the southeast of Asia. The trans-Gangetic peninsula is absent, but that of India proper is, for the first time in the history of geography, represented with a fair approximation to correct form and position. We really seem to see in this map something like the idea of Asia that the traveller himself would have presented, had he bequeathed us a map.

In the following age we find more frequent indications that Polo's book was diffused and read. And now that the spirit of discovery was beginning to stir, the work was regarded in a juster light as a book of facts, and not as a mere *Roman du Grant Kaan*. But the age produced new supplies of information in greater abundance than the knowledge of geographers was prepared to digest or co-ordinate; and, owing partly to this, and partly to his unhappy reversion to the fancy of a circular disk, the map of Fra Mauro (1459), one of the greatest map-making enterprises in history, and the result of immense labor in the collection of facts and the endeavor to combine them, really gives a much less accurate idea of Asia than the *Carta Catalana*.

When M. Libri, in his *Hist. des Sciences Mathématiques*, speaks of Columbus as "jealous of Polo's laurels," he speaks rashly. In fact Columbus knew of Polo's revelations only at second-hand, from the letters of the Florentine Paolo Toscanelli and the like; we cannot find that he ever refers to Polo by name. Though, to the day of his death, Columbus was full of imaginations about Zipangu (Japan) and the land of the Great Khan, as being in immediate proximity to his discoveries, these were but accidents of his great theory. It was his intimate conviction of the absolute smallness of the earth, of the vast extension of Asia eastward, and of the consequent narrowness of the western ocean on which his life's project was based.

When, soon after the discovery of the New World, attempts were made to combine the new and old knowledge,

the results were unhappy. The earliest of such combinations tried to realize the ideas of Columbus regarding the identity of his discoveries with the Great Khan's dominions; but even after America had vindicated its independent existence, and the new knowledge of the Portuguese had introduced China where the Catalan map had presented Cathay, the latter country, with the whole of Polo's nomenclature, was shunted to the north, forming a separate system. Henceforward the influence of Polo's work on maps was simply injurious; and when to his names was added a sprinkling of Ptolemy's as was usual throughout the 16th century, the result was a hotch-potch conveying no approximation to any representation of facts.

Gradually the contributions of Ptolemy and Polo are used more sparingly, but in Sanson's map (1659) a new element of confusion appears in numerous features derived from the "Nubian Geographer," i. e. Edrisi.

It is needless to follow the matter further. With the increased knowledge of northern Asia from the Russian side, and of China from the maps of Martini, followed by the later Jesuit surveys, and with the real science brought to bear on Asiatic geography by such men as De l'Isle and D'Anville, mere traditional nomenclature gradually disappeared; and the task which Polo has provided for the geographers of later days has been chiefly that of determining the true localities which his book describes under obsolete or corrupted names.

Before concluding, a word or two seems necessary on the subject of the alleged introduction of important inventions into Europe by Marco Polo. Assertions or surmises of this kind have been made in regard to the mariner's compass, to gunpowder, and to printing. Though the old assertions as to the first two are still occasionally repeated in books of popular character, no one who has paid any attention to the subject now believes Marco can have had anything to do with their introduction. But there is no doubt that the resemblance of early European block-books to those of China is in some respects so striking that it seems clearly to indicate the derivation of the art from that country. There is, however, not the slightest reason for connecting this introduction with the name of Polo. His fame has so overshadowed later travellers that the fact has been generally overlooked that for some years in the 14th century not only were missions of the Roman church established in the chief cities of eastern China, but a regular overland trade was carried on between Italy and China, by way of Tana (Azof), Astrakhan, Otrar, Kamul (Hami), and Kan-chow. Many a traveller other than Marco Polo might have brought home the block-books, and some might have witnessed the process of making them. This is the less to be ascribed to Polo, because he so curiously omits to speak of the process of printing, when in describing the block-printed paper-money of China, his subject seems absolutely to challenge a description of the art. (H. Y.)

POLOTSK, a district town of the government of Vitebsk, at the confluence of the Polota with the Dwina (Düna), 5 miles from the Smolensk and Riga Railway, is one of the oldest towns of Russia. The continuous wars, however, of which, owing to its position on the line of communication between central Russia and the west, it was for many centuries the scene, have allowed almost nothing of its remarkable antiquities to remain. The "upper castle" which stood at the confluence of the rivers and had a stone-wall with seven towers, is now in ruins, as also is the "lower castle," formerly enclosed with strong walls and connected with the upper by a bridge. The numerous monasteries and convents also have disappeared. The cathedral of St. Sophia in the upper castle, built in the 12th century, and successively used as a place of worship by the Greek, the Catholic, and the "United" Churches, fell to ruins in the 18th century, when the "United" bishop Grebnicki substituted a modern structure. The town is now of trifling importance, and the population (12,200 in 1880, against 13,800 in 1865) is decreasing. Upwards of two-thirds of the inhabitants are Jews; the remainder have belonged mostly to the Greek Church since 1839, when they were compelled to abandon the Union. Flax, linseed, corn, and timber are the leading articles of the commerce of the town.

Polotesk or Poltesk is mentioned in 862 as one of the towns given by Rurik to his men, together with Byelozero and Rostoff. In 980 it had a prince of its own, Rogvolod, whose daughter is the subject of many legends. It

remained an independent principality until the 12th century, resisting the repeated attacks of the princes of Kieff; those of Pskoff, Lithuania, and the Livonian knights, however, proved more powerful, and it fell under Lithuanian rule in the following century. About 1385 its independence was destroyed by the Lithuanian prince Witowt. It was five times besieged by Moscow in 1500-18, and was taken by John the Terrible in 1563. Recaptured by Stephen Batory sixteen years later, it became Polish by the treaty of 1582. It was then a populous city, which, enjoying the privileges of "Magdeburg law" from 1498, carried on an active commerce, and covered a large area. Pestilences and conflagrations were its ruin; the plague of 1566 wrought great havoc among its inhabitants, and that of 1600 destroyed 15,000. The castles, the town, and its walls were burned in 1607 and 1642. The Russians continued their attacks, burning and plundering the town, and twice taking possession of it for a few years, in 1633 and 1705. It was not definitively annexed, however, to Russia until 1772, after the first dismemberment of Poland. In 1812 its inhabitants resisted the French invasion, and the town was partially destroyed.

POLTAVA, a government of southwestern Russia, bounded by Tchernigoff on the N., Kharkoff on the E., Ekaterinoslaff and Kherson on the S., and Kieff on the W., and having an area of 19,265 square miles. Its surface is an undulating plain from 500 to 600 feet above sea-level, with a few elevations reaching 670 feet in the north, and gently sloping to the southwest, where its range is between 300 and 400 feet. Owing to the excavations of the rivers, their banks, especially those on the right, have the aspect of hilly tracts, while low plains stretch to the left. Low-lying districts with some marshes and sandy tracts are met with in the broad valley of the Dnieper, which skirts the province on the southwest. Almost the whole of the surface is covered with Tertiary deposits; chalk appears in the northeast, at the bottom of deeper ravines. The government touches the granitic region of the Dnieper only in the south, below Kremenchug. Limestone with dolerite veins occurs in the isolated hill of Isatchek, which rises above the marshes of the Sula. The whole is covered with a layer, 20 to 60 feet thick, of boulder clay, which, again, is often covered with a thick sheet of loess. Sandstone (sometimes suitable for grindstones) and limestone are quarried, and a few layers of gypsum and peat bog are also known within the government. The soil is on the whole very fertile, with the exception of some sandy tracts. Poltava is watered by the numerous tributaries of the Dnieper, which flows along its border, navigable throughout. Deep sand beds intersected with numberless ravines and old arms of the river stretch along the left bank, where accordingly the settlements are but few. It is joined by the Sula, the Psiol, the Vorskla, the Orel, the Trubezh, and several other tributaries, none of them navigable, although their courses vary from 150 to 270 miles in length. Even those which used to be navigated within the historical period, such as Trubezh and Supoy, are now drying up, while the others are being partially transformed into marshes. Only 5 per cent. of the total area is under wood; timber, wooden wares, and pitch are imported.

The population in 1881 reached 2,418,870, of whom 217,800 lived in towns. The great majority are Little Russians, there being only 20,000 Great Russians, less than 1000 White Russians, some 2000 Poles, and 1500 Germans. In 1865 the Jews were estimated at 40,000. Agriculture is the chief pursuit, there being 7,451,000 acres (60 per cent. of the total area) of arable land, and the average yield of the years 1870-77 being 6,302,000 quarters [50,416,000 bu.] of corn and 703,200 quarters [5,625,600 bu.] of potatoes. The crops chiefly grown are wheat, rye, and oats; the sunflower is largely cultivated, especially for oil, and the culture of tobacco, always important, has recently made a very great advance, now yielding about 200,000 cwts. Kitchen gardening, the culture of the plum, and the preparation of preserved fruits, are also important branches of industry. At Lubory, where an apothecaries' garden is maintained by the crown, the collection and cultivation of medicinal plants is also a specialty. The main source of wealth in Poltava always has been, and still is, its cattle-breeding. In 1881 there were 209,000 horses, 882,000 cattle, 1,820,000

sheep (only 520,000 of these, as against 878,000 in 1862, being of finer breeds), 405,000 pigs, and 7000 goats. Black and gray sheepskins are largely exported, as also is wool. Some of the wealthier landowners and many peasants now rear finer breeds of horses.

The aggregate value of the manufactures in 1879 was £1,112,100 [\$5,404,806], employing in their production 3755 hands; distilleries hold the leading place, (£171,500) [\$3,487,050], after which come flour mills (£136,600) [\$663,876], tobacco works (£79,700) [\$387,342], machine-making (£35,700) [\$173,502], tanneries (£27,700) [\$134,622], saw-mills (£20,000) [\$97,200], and sugar-works (£10,900) [\$52,974]. Wool is exported in a raw state, and the woollen manufactures amounted only to £5750 [\$27,945]. In the villages and towns several domestic trades are carried on, such as the preparation of sheepskins, plain woollen cloth, leather, boots, and pottery.

The fair of Poltava is of great importance for the whole woollen trade of Russia; leather, cattle, horses, coarse woollen cloth, skins, and various domestic wares are also exchanged for manufactures imported from Great Russia. The value of merchandise brought to the fair reaches and sometimes exceeds 25,000,000 [\$19,250,000 silver roubles] roubles. Several other fairs, the aggregate returns for which reach more than one-half of the above, are held at Romny (tobacco), Kremenchug (timber, corn, tallow, and salt), and Kobelyaki (sheepskins). Corn is exported to a considerable extent to the west and to Odessa, as also salt-petre, spirits of wine, wool, tallow, and plain woollen cloth. The navigation on the Dnieper is interfered with by want of water, and becomes active only in the south. The chief traffic is by railway.

The government is divided into fifteen districts, the chief towns of which are—Poltava (41,050 inhabitants), Gadyatch (9250), Khorol (5175), Kobelyaki (13,150), Konstantinograd (4320), Kremenchug (46,620 with Krukoff), Lohkvitsa (9320), Lubny (9820), Mirgorod (7750), Pereyaslafl (13,350), Piryatin (5400), Priluki (13,100), Romny (12,310), Zolotonosha (7180), and Zyenkoff (8360). Glinsk (3250) and Gradijsk (7850) have also municipal institutions, while several villages and towns (Sorotchintsy, Borispol, Smyeloye, Gruñ, Ryshetilovka, etc.) have from 6500 to 8000 inhabitants.

History.—At the dawn of Russian history the region now occupied by Poltava was inhabited by the Syeveryanes. As early as 988 the Russians erected several towns on the Sula and Trubezh for their protection against the Petchenegs and Polovtsy, who held the southeastern steppes. Population extended, and the towns Pereyaslafl, Lubny, Lukomy, Priluki, Piryatin, Romny, etc., begin to be mentioned in the 11th and 12th centuries. The Mongol invasion destroyed most of them, and for two centuries afterwards they totally disappear from Russian annals. About 1331 Gedimin annexed the so-called "Syeversk towns" to Lithuania, and on the recognition of the union of Lithuania with Poland they were included in the united kingdom along with the remainder of Little Russia. In 1476 a separate principality of Kieff under Polish rule and Polish institutions was formed out of Little Russia, and remained so until the rising of Bogdan Khmyelnitskii in 1654. By the Andrusoff treaty, the left bank of the Dnieper being ceded to Russia, Poltava became part of the dominions of the Zaporogian hetman, and was divided into "regiments," six of which (Poltava, Pereyaslafl, Priluki, Gadyatch, Lubny, and Mirgorod) lay within the limits of the present government. They lost their independence in 1764, and serfdom was introduced in 1783, the Poltava region becoming part of the governments of Kieff and Ekaterinoslafl. The present government was instituted in 1802.

POLTAVA, capital of the above government, stands on the right bank of the Vorskla, 88 miles by rail to the west-southwest of Kharkoff. The town is built on a plateau which descends by steep slopes nearly on all sides; the buildings are separated by large yards and gardens. Several suburbs, inhabited by Cossacks, whose houses are buried amid gardens, and a German colony, surround the town. Water is scarce, and has to be brought a long distance, from the marshy Vorskla. The oldest buildings are the Krestovozdvijenskiy monastery, erected in 1650, and a wooden church visited by Peter I. after the battle of Poltava. There are two lyceums for boys and girls, a "realschule," a military school for cadets, a theological seminary, and two girls' colleges, besides Russian, German, and Jewish primary schools. The manufactures are insignificant (£58,000 [\$281,880] in 1879); the principal are tobacco works (£27,500

[£133,650] and a tannery (£14,400) [\$69,984]. The trade derives its importance from the four fairs that are held at Poltava. The chief of these, in July (noticed above), is visited by 30,000 to 40,000 people. In 1881 the population was 41,050.

Poltava is mentioned in Russian annals in 1174, under the name of Ltava, but does not again appear in history until 1430, when, together with Glinsk, it was given by Gedymin to the Tartar prince Leksada. Under Bogdan Khmyelnitskii it was the chief town of the Poltava "regiment." Peter I. defeated Charles XII. in the immediate neighborhood on June 27, 1709.

POLYÆNUS, a Macedonian, lived at Rome as a rhetorician and pleader in the 2d century. When the Parthian War (162–165 A.D.) broke out, Polyænus, too old to share in the campaign, dedicated to the emperors Marcus Antonius and Lucius Verus a work, still extant, called *Strategica* or *Strategemata*, an historical collection of stratagems and maxims of strategy written in Greek and strung together in the form of anecdotes. It is not strictly confined to warlike stratagems, but includes also examples of wisdom, courage, and cunning drawn from civil and political life. The work is uncritically and negligently written, but is nevertheless important on account of the extracts it has preserved from histories now lost. It is divided into eight books, and originally contained nine hundred anecdotes, of which eight hundred and thirty-three are extant. Polyænus intended to write a history of the Parthian War, but there is no evidence that he did so. His works on Macedonia, on Thebes, and on tactics (if indeed this be not identical with the *Strategica*) are lost.

His *Strategics* seem to have been highly esteemed by the Roman emperors and to have been handed down by them as a sort of heirloom. From Rome it passed to Constantinople; at the end of the 9th century it was diligently studied by Leo VI., who himself wrote a work on tactics; and in the middle of the 10th century Constantine Porphyrogenitus mentioned it as one of the most valuable books in the imperial library. It was used by Strobeus, Suidas, and the anonymous author of the work *peri himeron* (*Mythographi Græci*, ed. Westermann, p. 323). It is arranged as follows: bks. i., ii., iii., stratagems occurring in Greek history, from the mythical times of Dionysus and Hercules onward; bk. iv., stratagems of the Macedonian kings and successors of Alexander the Great; bk. v., stratagems occurring in the history of Sicily and the Greek islands and colonies; bk. vi., stratagems of whole peoples (Carthaginians, Lacedæmonians, Argives, etc.), together with some of individuals (Philopœmen, Pyrrhus, Hannibal, etc.); bk. vii., stratagems of the barbarians (Medes, Persians, Egyptians, Thracians, Scythians, Celts); bk. viii., stratagems of Romans and women. This distribution is not, however, observed very strictly. Of the negligence or haste with which the work was written there are many instances: e.g., he confounds Dionysius the elder and Dionysius the younger, Mithradates satrap of Artaxerxes and Mithradates the Great, Scipio the elder and Scipio the younger; he mixes up the stratagems of Cæsar and Pompey; he brings into immediate connection events which were totally distinct; he narrates some events twice over, with variations according to the different authors from whom he draws. Though he usually abridges, he occasionally amplifies arbitrarily the narratives of his authorities. He never mentions his authorities, but amongst authors still extant he used Herodotus, Thucydides, Xenophon, Polybius, Diodorus, Plutarch, Frontinus, and Suetonius; amongst authors of whom only fragments now remain he drew upon Ctesias, Ephorus, Timæus, Phylarchus, and perhaps Aristagoras, Dinon, Heraclides, Megasthenes, and Nicolaus Damascenus. His style is clear, but monotonous and inelegant. He heaps up participles and falls alternately into the opposite faults of accumulating and totally omitting conjunctions. A glaring instance of these faults is to be found in bk. iii., 9, 33. In the forms of his words he generally follows Attic usage.

His work was first printed in a Latin translation by Justus Vultelus (Basel, 1549); the Greek text was first edited by Casaubon (Leyden, 1589), but mainly from a very inferior MS. Korais in his edition (Paris, 1809) corrected the text in many places. The best edition is that of Wölflin (Teubner, 1860), whose preface may be consulted with advantage.

POLYANTHUS. See PRIMROSE.

POLYBIUS, the historian, was a native of Megalo-

polis in Arcadia, the youngest of Greek cities (Paus. viii. 9), but one which played an honorable part in the last days of Greek freedom as a staunch member of the Achæan league. Polybius's father Lycortas was the intimate friend of Philopœmen, himself also a citizen of Megalopolis, and on the death of the latter, in 182 B.C., succeeded him as leader of the league. The date of Polybius's birth can only be fixed approximately. He tells us himself that in 181 he had not yet reached the age (? 30 years, Polyb., xxix. 9) at which an Achæan was legally capable of holding office (xxiv. 6). We learn from Cicero (*Ad Fam.*, v. 12) that he outlived the Numantine war, which ended in 132, and from Lucian (*Macrob.*, 22) that he died at the age of eighty-two. We may therefore follow the majority of authorities in placing his birth between 214 and 204 B.C. Little is known of his early life. As the son of Lycortas he was naturally brought into close contact with the leading men of the Achæan league. With the foremost of them, Philopœmen, he seems to have been on intimate terms. Plutarch (*ει πρασβ.*, 12) describes him as sitting at the feet of the great Achæan soldier, of whom Polybius himself always writes in terms of affectionate admiration; and after Philopœman's tragic death in Messenia (182) he was entrusted with the honorable duty of conveying home the urn in which his ashes had been deposited (Plut., *Phil.*, 11). The next year (181) witnessed what seems to have been his first entry into political life. Together with his father Lycortas and the younger Aratus, he was appointed, in spite of his youth, a member of the embassy which was to visit Ptolemy Epiphanes, king of Egypt,—a mission, however, which the sudden death of Ptolemy brought to a premature end, (xxv. 7). The next twelve years of his life are a blank, but in 169 he reappears as a trusted adviser of the Achæans at a difficult crisis in the history of the league. In 171 war had broken out between Rome and the Macedonian king Perseus, and the Achæan statesmen were divided as to the policy to be pursued: to side with Macedon would have been suicidal; Lycortas himself was in favor of neutrality, but there were good reasons for fearing that the Roman senate would regard neutrality as indicating a secret leaning towards Macedon, and indeed both Lycortas and Polybius himself had already incurred suspicion at Rome on this ground. Polybius therefore declared for an open alliance with Rome, and his views were adopted. It was decided to send an Achæan force to cooperate with the Roman general. Polybius was selected to command the cavalry, and was at once despatched to the Roman camp to announce the decision of the league (xxviii. 10 *sq.*). The Roman consul declined the proffered assistance, but Polybius accompanied him throughout the campaign, and thus gained his first insight into the military system of Rome. On his return home he was able to render an important service to his countrymen by checking the unauthorized attempt of a Roman officer to raise troops in Achaia (xxviii. 13). In the next year (168) both Lycortas and Polybius were on the point of starting at the head of 1200 Achæans to take service in Egypt against the Syrians, when an intimation from the Roman commander that armed interference was undesirable put a stop to the expedition (xxix. 23). The success of Rome in the war with Perseus was now assured, and it is possible that the readiness of Lycortas and Polybius to serve abroad was partly due to a belief that the fate of Macedon must soon be shared by Achaia. If this was so, the belief was but too well founded. The final defeat of Perseus was rapidly followed by the arrival in Achaia of Roman commissioners charged with the duty of securely establishing Roman interests there. As a result of their proceedings 1000 of the principal Achæans were arrested and carried off to Italy. Polybius was among the number, but, while his companions were condemned to a tedious incarceration

in the country towns of Italy, he obtained permission to reside in Rome. This privilege he owed to the influence of Æmilius Paullus, and his two sons Scipio and Fabius (xxxii. 9), who seem to have made his acquaintance in Macedonia. At any rate Polybius was received into Æmilius's house, and became the instructor of his sons (Appian, *Pun.*, 132). Between Scipio, the future conqueror of Carthage, and himself a friendship soon sprang up which ripened into a life-long intimacy. To the last Scipio so constantly relied upon the advice and counsel of Polybius that it could be said by the countrymen of the latter that Scipio never failed when he followed the advice of his friend (Pausan., viii. 30). To Polybius himself his friendship with Scipio was not merely the chief pleasure of his life but of inestimable service to him throughout his career. It protected him from interference, opened to him the highest circles of Roman society, and enabled him to acquire a personal influence with the leading men, which stood him in good stead when he afterwards came forward to mediate between his countrymen and Rome. It placed within his reach opportunities for a close study of Rome and the Romans such as had fallen to no historian before him, and secured him the requisite leisure for using them, while Scipio's liberality more than once supplied him with the means of conducting difficult and costly historical investigations (Pliny, *N. H.*, v. 9). In 151, after seventeen years of banishment, the few surviving exiles were allowed to return to Greece. But the stay of Polybius in Achaia was brief. The estimation in which he was held at Rome is clearly shown by the anxiety of the consul Mamilius (149) to take him as his adviser on his expedition against Carthage. Polybius started to join him, but broke off his journey at Coreyra on learning that the Carthaginians were inclined to yield and that war was unlikely (xxxvi. 3). But when, in 147, Scipio himself took command in Africa, Polybius hastened to join him, and was an eye-witness of the siege and destruction of Carthage (Appian, *Pun.*, 132). During his absence in Africa, the Achæans had made a desperate and ill-advised attempt to assert for the last time their independence of Rome,—a passionate outbreak which Polybius had dreaded, and which his presence might have prevented. As it was he returned in 146 to find Corinth in ruins, the fairest cities of Achaia at the mercy of the Roman soldiery, and the famous Achæan league shattered to pieces (Pol. ap. Strabo, p. 381). But there was still work to be done that he alone could do. All the influence he possessed was freely spent in endeavoring to shield his countrymen from the worst consequences of their rashness. The excesses of the soldiery were checked, and at his special intercession the statues of Aratus and Philopœmen were preserved (xxxix. 14). An even more difficult task was that entrusted to him by the Roman authorities themselves, of persuading the Achæans to acquiesce in the new régime imposed upon them by their conquerors, and of setting the new machinery in working order. With this work, which he accomplished so as to earn the heartfelt gratitude of his countrymen (xxxix. 16), his public career seems to have closed. The rest of his life was, so far as we know, devoted to the great history which is the lasting monument of his fame. He died at the age of eighty-two of a fall from his horse (Lucian, *Macrob.*, 22).

Of the forty books which made up the history of Polybius, the first five alone have come down to us in a complete form; of the rest we have only more or less copious fragments. But as to the general plan and scope of the work there is no room for doubt, thanks mainly to the clearness with which they are explained by Polybius himself. The task which he set himself was that of making plain, for the instruction of his own and future generations, how and why it was that "all the known regions of the civilized world had fallen under the sway of Rome" (iii. 1). This empire of Rome, unprecedented in its extent and still more so in the rapidity with which it had been acquired, was the standing

wonder of the age, and "who," he exclaims (i.1), "is so poorly spirited or indolent as not to wish to know by what means, and thanks to what sort of constitution, the Romans subdued the world in something less than fifty-three years?" These fifty-three years are those between 220 (the point at which the work of Aratus ended) and 168 B. C., and extend therefore from the outbreak of the Hannibalic war to the defeat of Perseus at Pydna. To this period then the main portion of his history is devoted from the third to the thirtieth book inclusive. But for clearness' sake he prefixes in books i. and ii. such a preliminary sketch of the earlier history of Rome, of the first Punic War, and of the contemporary events in Greece and Asia, as will enable his readers more fully to understand what follows. This seems to have been his original plan, but at the opening of book iii., written apparently after 146, he explains that he thought it desirable to add some account of the manner in which the Romans exercised the power they had won, of their temperament and policy, and of the final catastrophe which destroyed Carthage and forever broke up the Achaean league (iii. 4, 5). To this appendix, giving the history from 168-146, the last ten books are devoted.

Whatever fault may be found with Polybius, there can be no question that he had formed a high conception of the task before him, and of the manner in which it should be executed. He lays repeated stress on two qualities as distinguishing his history from the ordinary run of historical compositions. The first of these, its synoptic character, was partly necessitated by the nature of the period with which he was dealing. The interests, fortunes, and doings of all the various states fringing the basin of the Mediterranean had become so inextricably interwoven that it was no longer possible to deal with each of them in isolation. The historian must deal with this complex web of affairs as a whole, if he would be able either to understand or to explain it properly. Polybius therefore claims for his history that it will take a comprehensive view of the whole course of events in the civilized world, within the limits of the period with which it deals (i. 4). In doing so he marks a new point of departure in historical writing, "for we have undertaken," he says, "to record, not the affairs of this or that people, like those who have preceded us, but all the affairs of the known world at a certain time." In other words he aims at placing before his readers at each stage a complete survey of the field of action from Spain in the West to Syria and Egypt in the East. This synoptic method proceeds from a true appreciation of what is now called the unity of history, and to Polybius must be given the credit of having first firmly grasped and clearly enforced a lesson which the events of his own time were especially well calculated to teach. Posterity too has every reason to be grateful, for, though, as will be seen later, this synoptic method frequently interferes with the symmetry and continuity of his narrative, yet it has given us such a picture of the 2d and 3d centuries before Christ as no series of special narratives could have supplied.

The second quality upon which Polybius insists as distinguishing his history from all others is its "pragmatic" character. It deals, that is, with events and with their causes, and aims at an accurate record and explanation of ascertained facts. This "pragmatic method" (ix. 2) has a double value. First of all it makes history intelligible by explaining the how and the why; and, secondly, it is only when so written that history can perform its true function of instructing and guiding those who study it. For the great use of history according to Polybius is to contribute to the right conduct of human life (i. 35), by supplying a storehouse of experience for the assistance of those who will use it. But this it can only do if the historian bears in mind the true nature of his task. Above all things he must not content himself with merely writing a pleasant tale. He must remember that the historian should not write as the dramatist does to charm or excite his audience for the moment but to edify and instruct all serious students in the future (ii. 56). He will therefore aim simply at exhibiting events in their true light, setting forth "the why and the how" in each case not confusing causes and occasions, or dragging in old wives' fables, prodigies, and marvels (ii. 16; iii. 48). He will omit nothing which can help to explain the events he is dealing with: the genius and temperament of particular peoples, their political and military systems, the characters of the leading men, the geographical features of the country, must all be taken into account. To this conception of the aim and methods of history Polybius is on the whole consistently faithful in practice. It is true that his anxiety to instruct leads often to a rather wearisome iteration of his favorite maxims, and that his digressions, such as that on the military art, are occasionally provokingly long and didactic. But his comments and reflections are for the most part sound and in-

structive (e. g., those on the lessons to be learnt from the revolt of the mercenaries in Africa, i. 65; from the Celtic raids in Italy, ii. 35., and on the Roman character), while among his digressions are included such invaluable chapters as those on the Roman constitution (book vi.), the graphic description of Cisalpine Gaul (book ii.), and the account of the rise and constitution of the Achaean league (ii. 38 sq.). To his anxiety again to trace back events to their first causes we owe, not only the careful inquiry (book iii.) into the origin of the Second Punic War, but the sketch of early Roman history in book i., and of the early treaties between Rome and Carthage in iii. 22 sq. Among the many defects which he censures in previous historians, not the least serious in his eyes are their inattention to the political and geographical surroundings of the history (ii. 16; iii. 36), and their neglect duly to set forth the causes of events (iii. 6).

Polybius is equally explicit as regards the personal qualifications necessary for a good historian, and in this respect, too, his practice is in close agreement with his theory. He has a profound distrust of closet students and a profound belief in the value of a personal knowledge of affairs. Without such experience a writer will, he says, be guilty of endless blunders and omissions and will inevitably distort the true relations and importance of events. History, he asserts, will not be satisfactorily written until either men of affairs undertake to write it, not as a piece of by-work but as an honorable and necessary task, or until intending historians realize that some actual experience of affairs is indispensable (xii. 28). Such experience would have saved accomplished and fluent Greek writers like Timæus from many of their blunders (xii. 25a), but the shortcomings of Roman soldiers and senators like Q. Fabius Pictor show that it is not enough by itself. Equally indispensable is careful, painstaking research. All available evidence must be collected, thoroughly sifted, soberly weighed, and, lastly, the historian must be animated by a sincere love of truth and a calm impartiality. What follows where any or all of these conditions and qualifications are absent Polybius illustrates abundantly in his frequent and scathing criticisms on previous writers. In the case of Timæus, against whom he seems to cherish a peculiar animosity, nearly all that remains of book xii. is devoted to an exposition of his shortcomings. Q. Fabius Pictor and Philinus are charged both with ignorance of important facts and with partiality (i. 14; iii. 9), while in the second book Phylarchus's account of the war between the Achaean league and Cleomenes of Sparta is mercilessly dissected.

It is not possible here to discuss the question whether Polybius has been just to his predecessors; it is more important to consider how far he himself comes up to the standard by which he has tried others. In his personal acquaintance with affairs, in the variety of his experience and in his opportunities for forming a correct judgment on events he is without a rival among ancient historians. A great part of the period of which he treats fell within his own lifetime (iv. 2). He may just have remembered the battle of Cynoscephalæ (197). He must have been sixteen or seventeen years old at least when the power of Antiochus was broken at Magnesia (189), while of the events from 168-146 he was, as he tells us (iii. 4), not only an eyewitness but a prominent actor in them all. As the son of Lycortas he lived from his early youth in immediate contact with the foremost statesmen of the Peloponnese, while between 181 and 168 he was himself actively engaged in the military and political affairs of the Achaean league. The period of his exile in Rome served to add largely to his stores of experience; he was able to study at close quarters the working of the Roman constitution and the peculiarities of the Roman temperament; he made the acquaintance of Roman senators and became the intimate friend of the greatest Roman of the day. Lastly, he was able to survey with his own eyes the field on which the great struggle between Rome and Hannibal was fought out. He left Rome only to witness the crowning triumph of Roman arms in Africa and to gain a practical acquaintance with Roman methods of government by assisting in the settlement of his own beloved Achaia. When, in 146, his public life closed, he completed his preparation of himself for his great work by laborious investigations of archives and monuments and by a careful personal examination of historical sites and scenes. If to all this we add that he was deeply read in the learning of his day (*Elia*n, *Tact. i.*, ἀνὴρ πολυμαθής), above all in the writings of earlier historians, we must confess that, as at once scholar, statesman, soldier, and man of the world he was above all others fitted to write the history of the age of transition in which he lived.

Of Polybius's anxiety to get at the truth no better proof can be given than his conscientious investigation of origi-

nal documents and monuments and his careful study of geography and topography—both of them points in which his predecessors, as well as his successor Livy, conspicuously failed. Polybius is careful constantly to remind us that he writes for those who are φιλομαθείς, lovers, of knowledge, with whom truth is the first consideration. He closely studied the bronze tablets in Rome on which were inscribed the early treaties concluded between Romans and Carthaginians (see for these *Rhein. Mus.*, 32, 614; iii. 22-26). He quotes the actual language of the treaty which ended the first Punic war (i. 62), and of that between Hannibal and Philip of Macedon (vii. 9). In xvi. 15 he refers to a document which he had personally inspected in the archives at Rhodes, and in iii. 33 to the monument on the Laciunian promontory recording the number of Hannibal's forces. According to Dionysius, i. 17, he got his date for the foundation of Rome from a tablet in the pontifical archives. As instances of his careful attention to geography and topography we have not only the fact of his widely extended travels, from the African coast and the Pillars of Hercules in the west to the Euxine and the coasts of Asia Minor in the east, but also the geographical and topographical studies scattered throughout his history, such as the description of Sicily (i. 42), of Cisalpine Gaul (ii. 14) and of the Euxine (iv. 10), the discussion of Hannibal's route over the Alps and the graphic picture of the scene of the battle of Lake Trasimene. Lastly, to judge from its extant fragments, book xxxiv. seems to have been actually a treatise on geography in general.

Next to the duty of original research, Polybius ranks that of impartiality. Some amount of bias in favor of one's own country may, he thinks, be pardoned as natural (xvi. 14), but it must not be gratified at the expense of truth. It is unpardonable, he says, for the historian to set anything whatever above the truth. And on the whole Polybius must be allowed here again to have practiced what he preached. It is true that his own sympathies and antipathies are not entirely concealed. His affection for and pride in Arcadia appear in more than one passage (iv. 20, 21), as also does his dislike of the Æolians (ii. 45; iv. 3, 16). His treatment of Aratus and Philopemen, the heroes of the Achæan league, and of Cleomenes of Sparta, its most constant enemy, is perhaps open to severer criticism—it is at any rate certain that Cleomenes does not receive full justice at his hands. Similarly his views of Rome and the Romans may have been influenced by his firm belief in the necessity of accepting the Roman supremacy as inevitable and by his intimacy with Scipio, the head of the great patrician house of the Corneli. He has evidently a deep admiration for the great republic, for her well-balanced constitution, for her military system and for the character of her citizens. He shares too the dislike of the Roman aristocracy for such men of the people as Flaminius (ii. 21) and Varro (iii. 116). But just as his patriotism does not blind him to the faults and follies of his countrymen (xxxviii. 4, 5, 6), so he does not scruple to criticise Rome. He notices the incipient degeneracy of Rome after 146 (xviii. 35). He endeavors to hold the balance evenly between Rome and Carthage; he strongly condemns the Roman occupation of Sardinia as a breach of faith (iii. 28, 31); and he does full justice to the splendid generalship of Hannibal. Moreover, whether his liking for Rome was excessive or not, there can be no doubt that he has sketched the Roman character in a masterly fashion. Their ambition, their invincible confidence in themselves, their dogged courage, which made them more dangerous the harder they were pressed, and their devotion to the state are all clearly brought out. Nor does he show less appreciation of their practical sagacity, their readiness to learn from other peoples, their quickness in adapting their tactics both in war and diplomacy to changing circumstances, and their mastery of the art of ruling.

His interest in the study of character and his skill in its delineation are everywhere noticeable. He believes, indeed, in an overruling Fortune, which guides the course of events. It is Fortune which has fashioned anew the face of the world in his own time (iv. 2), which has brought the whole civilized world into subjection to Rome (i. 4), and the Roman empire itself is the most marvellous of her works (viii. 4). But under Fortune not only political and geographical conditions but the characters and temperaments of nations and individuals play their part. Fortune selects the best instruments for her purposes. The Romans had been fitted by their previous struggles for the conquest of the world (i. 63); they were chosen to punish the treachery of Philip of Macedon (xv. 4); and the greatest of them, Scipio himself, Polybius regards as the especial favorite of Fortune (xxiii. 15; x. 5).

The praise which the matter of Polybius's history deserves cannot be extended to its form, and in this respect

he contrasts sharply with Livy, whose consummate skill as a narrator has given him a popularity which has been denied to Polybius. Some of the most serious defects which spoil Polybius's history as a work of art are due to an over-rigid adherence to those views of the nature of the task before him which have been described above. His laudable desire to be comprehensive and to present a picture of the whole political situation at each important moment is fatal to the continuity of his narrative. The reader is hurried hither and thither from one part of the field to another in a manner at once wearisome and confusing. Thus the thrilling story of the Second Punic War is broken in upon by digressions on the contemporary affairs in Greece and in Asia. More serious, however, than this excessive love of synchronism is Polybius's almost pedantic anxiety to edify and to instruct. For grace and elegance of composition and for the artistic presentation of events he has a hardly concealed contempt. Hence a general and almost studied carelessness of effect, which mars his whole work. On the other hand, he is never weary of preaching. His favorite theories of the nature and aims of history, of the distinction between the universal and special histories, of the duties of an historian, sound as most of them are in themselves, are enforced again and again at undue length and with wearisome iteration. No opportunity is lost of pointing out the lesson to be learnt from the events described, and more than once the reader is irritated and the effect of a graphic picture is spoilt by obtrusive moralizing. Nor, lastly, is Polybius's style itself such as to compensate for these defects. It is indeed, often impressive from the evident earnestness and sincerity of the writer and from his sense of the gravity of his subject and is unspoilt by rhetoric or conceit. It has about it the ring of reality; the language is sometimes pithy and vigorous, and now and then we meet with apt metaphors, such as those borrowed from boxing (i. 57), from cock-fighting (i. 58), from draughts (i. 84). But in spite of these redeeming features, the prevailing baldness of Polybius's style excludes him from the first rank among classical writers, and it impossible to quarrel with the verdict pronounced by Dionysius of Halicarnassus, who places him among those authors of later times who neglected the graces of style, and who paid for their neglect by leaving behind them works "which no one was patient enough to read through to the end" (περί συνθέσεως, ἀνομάτων, 4.).

It is to the value and variety of his matter, to his critical insight, breadth of view, and wide research, and not least to the surpassing importance and interest of the period with which he deals, that Polybius owes his place among the writers of history. What is known as to the fortunes of his histories, and the reputation they enjoyed, fully bears out this conclusion. The silence respecting him maintained by Quintilian and by Lucian may reasonably be taken to imply their agreement with Dionysius as to his merits as a master of style. On the other hand Cicero (*De Off.*, iii. 32) describes him as "bonus auctor in primis"; in the *De Republica* (ii. 14) he praises highly his accuracy in matters of chronology, "nemo in exquirendis temporibus diligentior"; and Cicero's younger contemporary, Marcus Brutus, was a devoted student of Polybius, and was engaged on the eve of the battle of Pharsalia in compiling an epitome of his histories (Suidas, s. v.; Plutarch, *Brut.*, 4.). Livy, however, notwithstanding the extent to which he used his writings (see *LIVY*), speaks of him in such qualified terms as to suggest the idea that his strong artistic sensibilities had been wounded by Polybius's literary defects. He has nothing better to say of him than that he is "by no means contemptible" (xxx. 45), and "not an untrustworthy author" (xxxiii. 10). Posidonius and Strabo, both of them Stoics like Polybius himself, are said to have written continuations of his history (Suidas, s. v.; Strabo, p. 515). Arrian in the early part of the 2d and Ælian in the 3d century both speak of him with respect, though with reference mainly to his excellence as an authority on the art of war. In addition to his *Histories* Polybius was the author of the following smaller works: a life of Philopemen (Polyb., x. 24), a history of the Numantine War (Cic., *Ad Fam.*, v. 12), a treatise on tactics (Polyb., ix. 20; Arrian, *Tactica*; Ælian, *Tact.*, i.). The geographical treatise, referred to by Geminus, is possibly identical with the thirty-fourth book of the *Histories* (Schweigh., *Præf.*, p. 184.).

The complete books (i.-v.) of the *Histories* were first printed in a Latin translation by Nicholas Perotti in 1473. The date of the first Greek edition, that by Obsopœus, is 1580. For a full account of these and of later editions, as well as of the extant MSS., see Schweighäuser's Preface to his edition of Polybius. Our knowledge of the contents of the fragmentary books is derived partly from quotations in ancient writers, but mainly from two collections of excerpts; one, probably the work of a late Byzantine compiler, was first printed at Basel in 1549 and contains extracts from books vi.-xviii. (περί προέβλεψιν, περί ἀπεργίης και κακίας); the other consists of two fragments from the "select passages" from Greek historians compiled by the directions of Constantine

Porphyrogenitus in the 10th century. To these must be added the Vatican excerpts edited by Cardinal Mai in the present century.

The following are the more important modern editions of Polybius: Ernesti (3 vols., 1763-64); Schweighäuser (8 vols., 1793, and Oxford, 1823); Bekker (2 vols., 1844); L. Dindorf (4 vols., 1866-68, 2d ed., Teubner, 1882); Hultsch (4 vols., 1867-71). For the literature of the subject, see Englemann, *Biblioth. Script. Class.*: Script. Græci (pp. 646-650, 8th ed., Leipzig, 1880). (F. A. P.)

POLYCARP. The importance of Polycarp, bishop of Smyrna, for the earliest period of church history arises from his historical position. He was on the one hand a disciple of John and other apostles and disciples of Jesus; on the other hand he was the teacher of Irenæus, the first of the catholic fathers.¹ In his letter to Florinus, Irenæus (ap. Euseb., *H. E.*, v. 20) says:

"I saw you when I was yet, as a boy, in Lower Asia with Polycarp. . . . I could even now point out the place where the blessed Polycarp sat and spoke, and describe his going out and coming in, his manner of life, his personal appearance, the addresses he delivered to the multitude, how he spoke of his intercourse with John and with the others who had seen the Lord, and how he recalled their words. And everything that he had heard from them about the Lord, about His miracles and His teaching, Polycarp told us, as one who had received it from those who had seen the Word of Life with their own eyes, and all this in complete harmony with the Scriptures. To this I then listened, through the mercy of God vouchsafed to me, with all eagerness, and wrote it not on paper, but in my heart, and still by the grace of God I ever bring it into fresh remembrance."

These are priceless words, for they establish a chain of tradition (Jesus, John, Polycarp, Irenæus) which is without a parallel in history. It is all the more to be regretted that Irenæus in his great work² has said so little of Polycarp, and that neither Polycrates of Ephesus³ nor Tertullian⁴ mentions anything of importance.

The sources for the life and activity of Polycarp are as follows: (1) a few notices of Irenæus; (2) the epistle of Polycarp to the church at Philippi; (3) the epistle of Ignatius to Polycarp; (4) the epistle of the church at Smyrna to the church at Philomelium, giving an account of the martyrdom of Polycarp. Since these authorities have all been called in question, and some of them entirely rejected, by recent criticism, it is necessary to say a few words about each of them.

1. Of the statements of Irenæus, those contained in the letter to Victor and in the large work have passed unchallenged. The letter to Florinus, however, which places Polycarp in unequivocal connection with the apostle John, has been discredited, because it is alleged, John never was in Asia Minor. But this denial of John's residence in Asia Minor is itself a piece of critical arbitrariness, and to assert that the epistle to Florinus is spurious is a desperate resource. The only argument which can be adduced against it with any sort of plausibility is the fact that in his great work Irenæus does not satisfy the expectations which the letter to Florinus is apt to raise in a modern reader. It is certainly the case that he tells us very little about Polycarp and still less about John. But statements from the mouth of Polycarp of the very kind which the letter to Florinus would lead us to expect are not altogether wanting in the great work of Irenæus (see iii. 3, 4; ii. 22, 5; v. 30, 1)⁵; and that they are so few is accounted for by the plan and object of the treatise. The facts mentioned by Irenæus, therefore, cannot be set aside, although the assertion that Polycarp was appointed bishop of the church at Smyrna by the apostles (iii. 3, 4) is probably a deduction from the catholic theory of the origin of the episcopate. If it was once understood that Polycarp had seen apostles, the necessary inference for the time of Irenæus was that he had received his office from the hands of the apostles.

2. Under the name of Polycarp we possess in a Latin translation, a complete letter to the church at Philippi, which was first published by Faber Stapulensis in 1498. Of the Greek original, which was first edited by Halloix in 1633,

unfortunately only three-fourths has been preserved.⁶ Since Irenæus (iii. 3, 4) expressly mentions and commends a letter of Polycarp to the church of Philippi, since Eusebius (*H. E.*, iii. 36) was acquainted with the epistle as we have it and makes extracts from it, and since Jerome (*De Vir. Ill.*, xvii.) testifies that in his time it was publicly read in the Asiatic churches, the external evidence in its favor is as strong as could be desired. But the internal evidence is also very strong. The occasion of the letter was a case of embezzlement, the guilty individual being a presbyter at Philippi. It shows a fine combination of mildness with severity; the language is simple but powerful; and, while there is undoubtedly a lack of original ideas, the author shows remarkable skill in weaving together pregnant sentences and impressive warnings selected from the apostolic epistles and the first epistle of Clement. There is no trace of any tendency beyond the immediate purpose of maintaining the true Christian life in the church, and warning it against covetousness and against an unbrotherly spirit. In these circumstances it would certainly never have occurred to any one to doubt the genuineness of the epistle, or to suppose that it had been interpolated, but for the fact that in several passages reference is made to Ignatius and his epistles. In point of fact the historical situation which is presupposed by the epistle is this, that Ignatius, on his last journey to Rome, has just passed through Philippi, and that his letters are circulating in the churches. Hence all those scholars who hold the seven Ignatian epistles to be spurious are compelled to regard the epistle of Polycarp as also a forgery,⁷ or at least as having been largely interpolated.⁸ The interpolation hypothesis, however breaks down in view of the fact that the first epistle of Clement is quoted even in those passages which are alleged to be interpolated; and besides it is inconsistent with the very obvious arrangement and unity of the composition. On the other hand the assumption that the whole work is a forgery is untenable—(1) because in that case we should expect that its tone and language and tendency would be in keeping with the Ignatian epistles, which is very far from being the fact, and (2) because we must assume that Irenæus himself had been deceived by a forged epistle of Polycarp, or else that he had read the genuine epistle, but in the course of the 3d century it had been supplanted by a spurious substitute. Either of these suppositions is extremely improbable, and, since internal marks of forgery are altogether absent, we must rather reverse the argument and say that the epistle of Polycarp is a very important piece of evidence for the historical existence of a bishop of Antioch named Ignatius, for his journey to martyrdom at Rome, and for the fact that on this journey he wrote several letters. In these circumstances it is very desirable that we should be able to fix the exact date of Polycarp's epistle. This unfortunately is impossible, owing to the colorless character of the writing. Still it is noteworthy that there is not a single trace of the time of Trajan, that on the contrary an expression in the seventh chapter seems to presuppose the activity of Marcion.⁹ In that case the letter cannot have been written before 140 A.D. The Ignatian epistles and the history of Ignatius furnish no argument to the contrary, for the idea that Ignatius was martyred under Trajan cannot be traced higher than the 3d century,¹⁰ while the chronological indications in the Ignatian epistles themselves point to a later period. The epistle of Polycarp is of more importance for the Ignatian problem than for Polycarp himself. It conveys no distinct impression of his individuality, beyond the fact that the writer of this letter lived wholly in the ideas of the older generation and of the apostles, and would admit no addition to their teaching. That, however, is a feature which harmonizes admirably so far as it goes with the description which Irenæus gives of Polycarp in the letter to Florinus. On account of its dependence on older epistles, the epistle of Polycarp is of great value for the history of the canon. For the constitutional history of the church also it contains valuable materials; but for the history of dogma it is of little use.

3. The epistle of Ignatius to Polycarp is an important document, whether it is genuine or not. It belongs at any rate to the 2d century, so that even if it were spurious it would at least show what conception of the bishop's character was then prevalent. Polycarp appears in the letter as a man of a passive disposition, with too little energy and decision for the vehement Ignatius. The admonitions which

⁶ All the Greek MSS. are derived from a single archetype, in which the epistle of Barnabas followed that of Polycarp, but a sheet of four leaves had been torn out, so that the end of Polycarp's epistle and the beginning of that of Barnabas are missing.

⁷ So, for example, Lipsius, Hilgenfeldt and others.

⁸ So Döllinger, first of all, then Bunsen and Ritschl (*Entstehung der altkathol. Kirche*, 2d ed., p. 584 sq.).

⁹ Compare vii. 1 with Iren. iii. 3, 4.

¹⁰ See Harnack, *Die Zeit des Ignatius*, 1878.

¹ Iren., iii. 3, 4.

² The lost writings of Irenæus may have contained fuller information; see the close of the *Martyrium Polycarpi* in the Cod. Mosq., and the letter of Irenæus to Victor in Eusebius (*H. E.*, v. 24).

³ Euseb., *H. E.*, v. 24, 4.

⁴ *De Præscr. Hæc.* 32.

⁵ Cf. "Presbyterorum reliquiæ ab Irenæo servatæ" in the *Patr. App. Opp.*, ed. Gebhardt, Harnack, Zahn, vol. i. 2, p. 105 sq.

Ignatius thinks fit to bestow on Polycarp (c. 1-6) are surprising, when we remember that they are addressed to an old and venerable man. But Ignatius was writing under the consciousness of impending martyrdom, and evidently felt, with all his affected modesty, that this gave him a right to censure the churches and bishops of Asia. To pronounce the epistle spurious on account of its tone is hazardous, because it is difficult to imagine how it could have entered the head of a forger to subject the honored Polycarp to such treatment at the hands of Ignatius.

4. The most valuable source for the history of Polycarp is the letter of the church in Smyrna about his martyrdom. Eusebius has preserved the greater part of this epistle in his *Church History* (iv. 15); but we possess it entire with various concluding observations in several Greek manuscripts, and also in a Latin translation.¹ The epistle gives a minute description of the persecution in Smyrna, of the last days of Polycarp, and of his trial and martyrdom; and, as it contains many instructive details, and professes to have been written not long after the events to which it refers, it has always been regarded as one of the most precious remains of the 2d century. Certain recent critics, however, have questioned the authenticity of the narrative. Lipsius² brings the date of the epistle down to about 260, although he admits many of its statements as trustworthy. Keim³ endeavors to show in a long dissertation that it could not possibly have been written shortly after the death of Polycarp, but that, although based on good information, it was not composed till the middle of the 3d century. But Keim's own investigation is sufficient to convince every unprejudiced mind that the genuineness of the epistle will bear the closest scrutiny, for the arguments he advances are of no value.⁴ The only positions which Keim (following in the wake of others⁵) makes good are that a few slight interpolations⁶ have been inserted in the epistle, and that it was written, not a few days, but perhaps a year or two after the death of Polycarp. The statement in the epistle that Polycarp suffered martyrdom under the proconsulate of Quadratus has quite recently given rise to a voluminous literature. Eusebius in his *Chronicle* gives 166 A.D. as the year of Polycarp's death, and until the year 1867 this statement was never questioned. In that year appeared Waddington's "Mémoire sur la chronologie de la vie du rhéteur Élius Aristide" (*Mém. de l'Institut. imp. de France*, 1867, xxvi.), in which it was shown from a most acute combination of circumstances that Quadratus was proconsul of Asia in 155-6, and that consequently Polycarp was martyred on the 23d of February, 155.⁷ Since the date of Polycarp's death is of great importance for the chronology of many other events, and since it is an unusual thing in the history of criticism for the date of any occurrence to be thus put eleven years farther back, Waddington's arguments have been examined by a great number of critics. Renan,⁸ Aube,⁹ Hilgenfeld,¹⁰ Gebhardt,¹¹ Lipsius,¹² Harnack,¹³ Zahn,¹⁴ Egli,¹⁵ and others have declared themselves satisfied, although some scholars regarded 156 as also a possible date. On the other hand Keim,¹⁶ Wieseler,¹⁷ and Uhlhorn,¹⁸ join issue with Waddington and adhere to the date of Eusebius. The arguments on which they rely do not appear to the present writer to be convincing, and it may be asserted with great probability that the martyrdom of Polycarp took place on the 23d of February 155.¹⁹ Besides these we have no other sources for the life of Polycarp. The *Vita S. Polycarpi auctore Pionio* (published by Duchesne, Paris, 1881, and Funk, *Apost. Patr. Opp.*, vol. ii. p. 315 sq.) is worthless.²⁰

The chief facts to be gathered about the life of Polycarp from the above sources are these. He must have been born before the year 69, for on the day of his death he declared that he had served the Lord for eighty-six years (*Martyrium*, ix.). He became a Christian in his earliest youth, and was an associate of the apostle John and other disciples of Jesus who had come from Palestine to Asia Minor. What he heard from them he kept in life-long remembrance, and in his manhood and old age he used to gather the young people round him, and repeat to them what he had learned from those who had seen Christ in the flesh. Amongst these youthful hearers was Irenæus, who has recorded much of what he thus learned (for example, an encounter between John and Cerinthus in the bath, a statement about the age of Jesus, etc.). Especially when heresy began to raise its head, the aged Polycarp never ceased to appeal to the pure doctrine of the apostles. He lived to see the rise of the Marcionite and Valentinian sects, and vigorously opposed them. Irenæus tells us that on one occasion Marcion "endeavored to establish relations with him" (Iren., iii. 3, 4), and accosted him with the words ἐπιγινώσκες ἡμᾶς; there is no doubt that Marcion wished to be on friendly terms with so influential a man; but Polycarp displayed the same uncompromising attitude which his master John had shown to Cerinthus, and answered ἐπιγινώσκω σε τὸν πρωτότοκον τοῦ Σατανᾶ. These stern words are again applied to Marcion in the epistle to the Philippians; for it is undoubtedly Marcion who is referred to in the following passage (c. vii.): "He who falsifies the sayings of the Lord after his own pleasure, and affirms that there is no resurrection [of the flesh] and no judgment, is the first-born of Satan." The steady progress of the heretical movement, in spite of all opposition, was a cause of deep sorrow to Polycarp, so that in the last years of his life (Iren. ap. Euseb., v. 20) the words were constantly on his lips, "Oh, good God, to what times hast thou spared me, that I must suffer such things." He never allowed himself to engage in discussion with heretics, but as far as possible avoided their presence. Even in early life he had become the head of the church of Smyrna, where he was held in the highest respect. The congregation looked up to him as an apostolic and prophetic teacher (*Mart.*, xvi.), and consequently as combining in himself all the spiritual gifts which God had conferred on Christendom. In his old age the members of the congregation vied with each other in providing for his support (*ibid.*, xiii.). How great his reputation was is best shown by the fury of the heathen and the Jews in his martyrdom. He was arrested amidst shouts of "This is the teacher of Asia; this is the father of the Christians; this is the destroyer of our gods; this is the man who has taught so many no longer to sacrifice and no longer to pray to the gods" (*ibid.*, xii.). When sentence was pronounced against him, every creature of the Jewish and heathen rabble hastened to add something to the pile of wood on which he was to be burned (*ibid.*, xiii.). They refused to deliver up his bones to the Christians for burial, for, said the Jews to the mob, "The Christians will now forsake the Crucified, and worship Polycarp" (*ibid.*, xvii.). The sacrifice of Polycarp immediately quenched the fury of the multitude, and the persecution ceased. All these facts prove the great influence which the bishop had in the city. But his reputation extended far beyond the limits of his own diocese. His letter to the church at Philippi shows us how fully his apostolic spirit, his wisdom and justice, must have been recognized even in Macedonia; otherwise he could not have ventured to interfere in the purely internal affairs of the Philippian church. Ignatius, the bishop of Antioch, begins his letter to him with the words (c. 1) — Ἀποδεχόμενός σου τὴν ἐν θεῷ γνώμην, ἡδρασμένην ὡς ἐπὶ πέτρᾳ ἀκίνητον, ὑπερδοξάζω, καταξιώθεὶς τοῦ προσώπου σου τοῦ ἁγίου, οὐ δύναμιν ἐν θεῷ, and, in spite of his patronizing tone, evidently writes with deep respect. But

even the church at Rome were to have an opportunity of making the acquaintance of the venerable bishop. It is one of the most interesting and important incidents in the church history of the 2d century that Polycarp, in the year before his death (when he was above ninety years of age) undertook the journey to Rome in order to visit the bishop Anicetus.¹ Irenæus, to whom we are indebted for this information (*Hær.* iii. 3, 4; *Ep. ad Victorem*, in Eusebius, *H. E.*, v. 24, 16-17), gives as the reason for the journey that differences existed between Asia and Rome, or between Polycarp and Anicetus, "with regard to certain things," and especially about the time of the Easter festival, which it was desirable to remove. He might easily have told us what these "certain things" were, and given us fuller details of the negotiations between the two great bishops; for in all probability he was himself in Rome at the time (*Mart.*, Epilog. Mosq.). But unfortunately all he says is that, with regard to the "certain things," the two bishops speedily came to an understanding, while, as to the time of Easter, each adhered to his own custom without breaking off communication with the other. We learn further that Anicetus, as a mark of special honor, allowed Polycarp to celebrate the Eucharist in the church (the Eucharist must therefore have still been celebrated at Rome in the Greek tongue), that many Marcionites and Valentinians were converted by Polycarp in Rome (so that his visit must have lasted for a considerable time), and that Polycarp took leave of Anicetus in peace. On his return to Smyrna he enjoyed only about six months of uninterrupted activity. Then, on the occasion of the festive games, there arose, as in so many other instances, an outburst of popular feeling against the Christians, in which Polycarp was to die a martyr's death. From the letter of the church of Smyrna we see with what magnanimity and manliness and true Christian spirit the gray-haired bishop conducted himself. It leaves the most vivid impression of a man of dignity and noble demeanor, and at the same time of humble disposition and compassionate love. Every action he does, every word he speaks, in the prosecution and during the trial is noble and great; even that quiet irony which we detect in his answer to Marcion does not forsake him (*Mart.*, ix. 2). The proconsul was anxious to save him, and tried to induce him to recant, but he remained steadfast. He was delivered up to the populace, and his body was burned. The Christians present believed that they saw a dove soaring aloft from the burning pile, and it was reported that an odor issued from it like that of costly incense (*ibid.*, xvi. 15). Such legends do not require years for their formation, but only a few hours. By his death Polycarp shielded his congregation from further persecution. (A. HA.)

POLYCLETUS. Two Greek sculptors bore this name. For an account of the works of the elder, a native of Sicily, see vol. ii. p. 312, and Figs. 6, 7. With him is sometimes confounded his younger kinsman and namesake, properly known as Polycleus the Argive. For the most part this younger Polycleus confined himself to statues of athletes who had won prizes at Olympia. In recent excavations there two bases of statues by him have been found, but no remains of his work. From the fact of his having executed a statue of Zeus Philios, i.e., a combination of Zeus and Dionysus, for the town of Megalopolis, which was founded in 371 B.C., we may assign him to about that date.

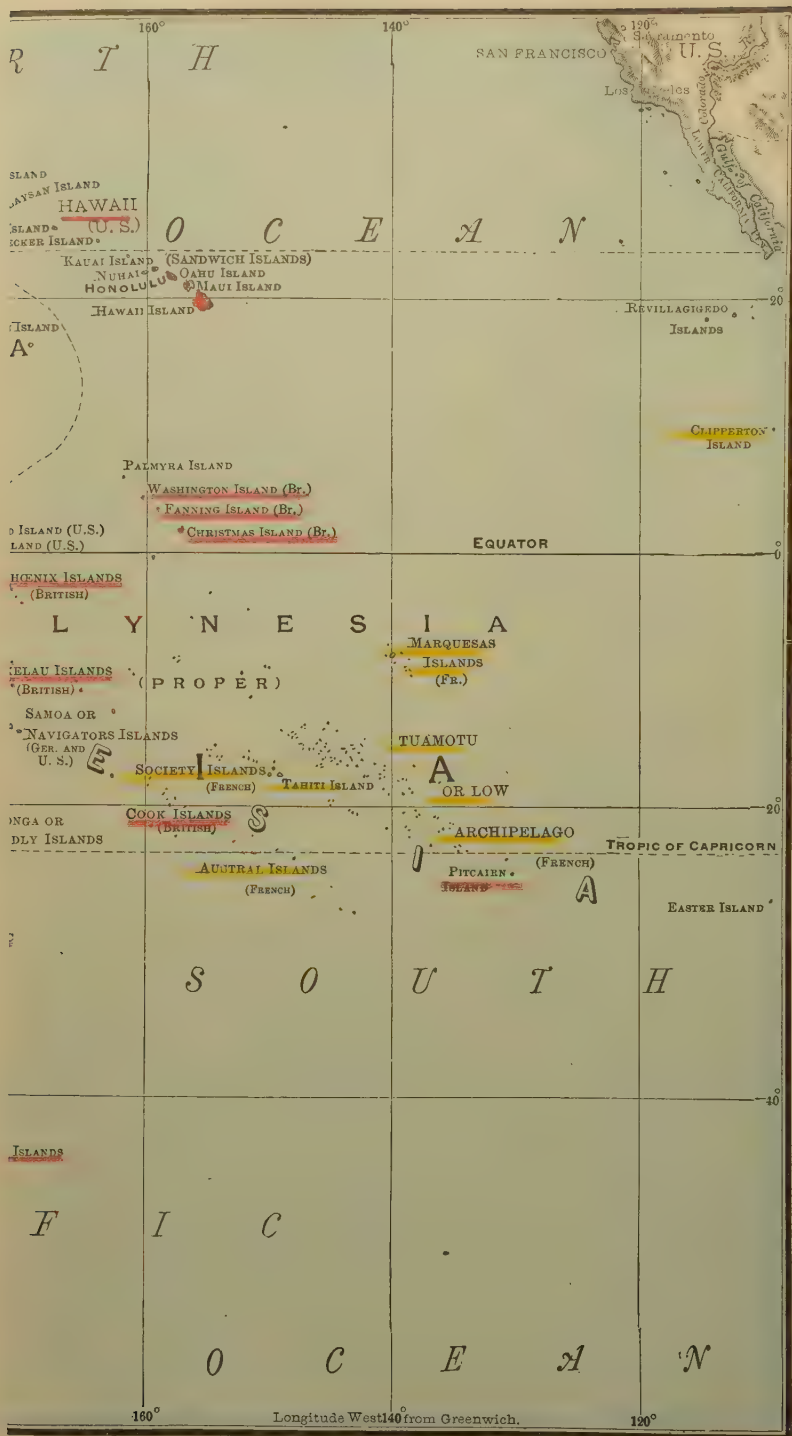

¹ Anicetus was bishop from 154 (156) to 166 (167) (see Lipsius, *Chron. d. Röm. Bischöfe*, § 263). Those critics who reject Waddington's view as to the date of Polycarp's death use this as their principal argument, that according to it there is no room for Polycarp's journey to Rome. It is certainly remarkable that the journey can just be brought under Waddington's calculations and no more; but, since after all it can be brought under them, no conclusive argument can be drawn from this circumstance. A voyage to Rome at a favorable season of the year was not a very formidable affair, and that Polycarp was still comparatively vigorous is shown by his conduct during the persecution (*Mart.*, v. sq.).

POLYCRATES, a celebrated Greek tyrant of Samos, was the son of Ææces. After distinguishing himself by his liberality towards his poorer fellow-citizens he took advantage of a festival to Hera in order to make himself master of Samos (537 or 536 B.C.).² Allied with Amasis, king of Egypt, he prospered greatly, so that his fame went forth through all Greece and Ionia. He had 100 ships and 1000 bowmen. He made war indiscriminately on friend and foe, declaring with grim humor that he gratified his friends more by returning to them their own than by not taking it at all. Many islands fell before him and many cities on the mainland. Amongst the former was Rhenea, which he attached by a chain to the neighboring island of Delos, and dedicated to the Delian Apollo. When the Lesbians would have succored Miletus, he conquered and captured them in a sea-fight and employed them to dig a moat round the walls of his fortress. According to Herodotus, he was the first within historical times who aimed at the sovereignty of the seas, and his ambitious schemes embraced not only the Greek islands but also Ionia. In magnificence none of the Greek tyrants save those of Syracuse could compare with him. His great public works were executed, according to Aristotle, for the purpose of employing his subjects and diverting their thoughts from the recovery of their freedom.³ He imported Spartan and Molossian hounds, goats from Naxos and Scyros, sheep from Attica and Miletus. The splendor of his palace is attested by the design which many centuries later the emperor Caligula formed of rebuilding it. Foreign artists worked for him at high wages; from Athens he brought Demacædes, the greatest physician of the age, at a salary of two talents. Polycrates was also a patron of letters: he collected a library and lived on terms of intimate friendship with the poet Anacreon, whose verses were full of references to his patron. The philosopher Pythagoras, however, quitted Samos in order to escape his tyranny. The good fortune of Polycrates is the subject of a famous story. Amasis, moved with fear at the exceeding great prosperity of his friend, reminded him that God is jealous, and that the man who is uplifted very high must needs fall very low. Therefore he besought him, if he would avert the jealous wrath of heaven, to cast from him that which he valued most. Polycrates hearkened to him and flung into the sea an emerald signet set in gold, the work of the Samian artist Theodorus. But a few days after the signet was found in the belly of a large fish which a fisherman had presented to the king. When Amasis heard of this he knew that Polycrates was doomed, and renounced his alliance. Amasis died before his forebodings were fulfilled. When the Persians under King Cambyses were preparing to invade Egypt, Polycrates anxious to conciliate the growing power of Persia, sent forty ships to their help (525 B.C.). But the squadron was largely manned by malcontents whom Polycrates had hoped thus to get rid of; hardly had it reached the island of Carpathus when the crews mutinied and turned the ships' heads back to Samos. They defeated the tyrant in an action at sea, but were themselves overthrown in a land battle and compelled to flee the island. Having taken refuge in Sparta, they prevailed on the Spartans to make war on Polycrates. A powerful Spartan armament laid siege to Samos, but was fain to retire after forty days without effecting its

² Eusebius gives the date as 1484 (year of Abraham) = Olymp. 61,4 = October, 537 to October, 532. But codex N of the Armenian version of Eusebius has Abrah. 1480 = Olymp. 60,4 = Oct., 537 to Oct., 536. The former date, accepted by Clinton, would leave only ten years for the tyranny of Polycrates, which seems too little.

³ Herodotus, our chief authority for the life of Polycrates, mentions three great engineering and architectural works for which Samos was remarkable: (1) a tunnel, about 1400 yards long, dug through a mountain, and serving to bring water to the capital; (2) a great mole or breakwater round the harbor; (3) a great temple (the temple of Hera, patron goddess of Samos), said by Herodotus to be the largest he had ever seen. But we cannot say what share Polycrates had in these works; certainly the temple of Hera seems to have been begun before his time.

object. Not very long afterwards Oroetes, the Persian satrap of Sardes, by working on the avarice and ambition of Polyocrates, lured him to Magnesia and put him to a shameful death (522 B.C.).

The name of Polyocrates was also borne by an Athenian rhetorician of some repute, who flourished early in the 4th century B.C. He taught at Athens, and afterwards in Cyprus. He composed declamations on paradoxical themes—an *Encomium on Clytemnestra*, an *Accusation of Socrates*, an *Encomium on Busiris* (a mythical king of Egypt, notorious for his inhumanity); also declamations on wine, pots, and counters. His *Encomium on Busiris* was sharply criticised by his younger contemporary Isocrates, in a work still extant, and Dionysius of Halicarnassus characterizes his style as frigid, vulgar, and inelegant. Nevertheless his works are said to have been studied by Demosthenes. See Jebb's *Attic Orators*, ii. p. 94; Cope on Aristotle's *Rhetoric*, ii. c. 24.

POLYGLOTT. A polyglott is a book which contains side by side versions of the same text in several different languages; and the most important polyglotts are editions of the Bible, or its parts, in which the Hebrew and Greek originals are exhibited along with the great historical versions, which are of value for the history of the text and its interpretation. The first enterprise of this kind is the famous *Hexapla* of Origen; but here only Hebrew and Greek were employed (though the versions of Aquila, Symmachus, and Theodotion were shown as well as the Septuagint), so that the work was rather diglott than polyglott in the usual sense. After the invention of printing and the revival of philological studies, polyglotts became a favorite means of advancing the knowledge of Eastern languages (for which no good helps were available) as well as the study of Scripture. The series began with the *Complutensian* (Alcala, 1514-17), already spoken of in the article on its promoter Cardinal JIMENES or Ximenes; next came the *Antwerp Polyglott* (1569-72, in 8 vols. folio) of which the principal editor was Arias Montanus aided by Guido Fabricius Boderianus, Raphaelengius, Masius, Lucas of Bruges, and others. This work was under the patronage of Philip II. of Spain; it added a new language to those of the *Complutensian* by including the Syriac New Testament; and, while the earlier polyglott had only the Targum of Onkelos on the Pentateuch, the Antwerp Bible had also the Targum on the Prophets, and on Esther, Job, Psalms, and the Salomonic writings. Next came Le Jay's *Paris Polyglott* (1645), which embraces the first prints of the Syriac Old Testament (edited by Gabriel Sionita, a Maronite, but the book of Ruth by Abraham Ecchelenis, also a Maronite) and of the Samaritan Pentateuch and version (by MORINUS, *q.v.*). It has also an Arabic version, or rather a series of various Arabic versions. Le Jay's work is a splendid piece of typography, but its success was marred by the appearance of the cheaper and more comprehensive *London Polyglott*. Le Jay was ruined, and a great part of the impression went to the trunkmakers. The last great polyglott is Walton's (London, 1657), which is much less beautiful than Le Jay's, but more complete in various ways, including among other things the Syriac of Esther and several apocryphal books for which it is wanting in the Paris Bible, Persian versions of the Pentateuch and Gospels, the Psalms and New Testament in Ethiopic. Walton was aided by able scholars, and used much new manuscript material. His prolegomena, too, and collections of various readings mark an important advance in Biblical criticism. It was in connection with this polyglott that E. Castle produced his famous *Heptaglott Lexicon* (London, 2 vols. folio, 1669), an astounding monument of industry and erudition even when allowance is made for the fact that for the Arabic he had the great MS. lexicon compiled and left to the university of Cambridge by the almost forgotten W. Bedwell. The later polyglotts are of little scientific importance, the best recent text having been confined to a single language; but every Biblical student still

uses Walton and, if he can get it, Le Jay. Of the numerous polyglotts on parts of the Bible it may suffice to mention the Genoa psalter of 1516, edited by Giustiniani, bishop of Nebbio. It is in Hebrew, Latin, Greek, Chaldee, and Arabic, and is interesting from the character of the Chaldee text, from being the first specimen of Western printing in the Arabic character, and from a curious note on Columbus and the discovery of America on the margin of Psalm xix.

POLYGNOTUS, a Greek painter. For a description of his work see vol. ii. p. 313. It may here be added that an approximate date for his paintings at Delphi is obtained from the fact that one of them was inscribed with an epigram written by the poet Simonides, who died 467 B.C. As Simonides appears to have resided in Sicily during the last ten years of his life, the epigram was probably composed previous to 477 B.C. This series of mural paintings at Delphi, embracing about one hundred and forty-six figures, seems to have occupied two opposite walls of an oblong building known as the Lesche. The figures, hardly under life size, were disposed in two or sometimes three rows, the one higher up than the other, with apparently but very slight indications of the fact that the figures of the upper rows were to be understood as standing at a more remote distance. The several rows would run continuously like sculptured friezes, and indeed this manner of composition is best illustrated by the friezes at Vienna recently found at Gjölboxhi in Lycia, some of which present subjects and motives identical with those treated by Polygnotus.

POLYHISTOR, CORNELIUS ALEXANDER, a Milesian and disciple of Crates,¹ who through the fortune of war became the slave and afterwards the freedman of Cornelius Lentulus (Suidas). He received the Roman citizenship from Sulla (Servius on *Æn.* x. 388), and wrote an enormous number of books on historical and geographical subjects, of which more than a hundred and fifty fragments have been collected (Müller, *Fr. Hist. Gr.*, iii. 206 sq.). His account of the doctrines of Pythagoras has been largely drawn from by Diogenes Laertius, but the most interesting of the fragments refer to the history of the Jews, for which Alexander drew on historical and poetical works of Jewish and Samaritan Hellenists. What has been preserved on this subject, mainly by Eusebius in the *Præparatio Evangelica*, is sufficient to throw a good deal of light, not particularly favorable, on the intellectual activity of the Hellenists of the 2d century B.C.

See J. Freudenthal, *Hellenistische Studien*, i. ii. (Breslau, 1875), in which the subject of the sources of Polyhistor is fully discussed.

POLYNESIA. In the last edition of the *Encyclopædia Britannica* Polynesia was used to Plate III. denote all the intertropical islands of the Pacific Ocean eastward of the Philippine Islands to the north and the new Hebrides to the south of the equator. The New Hebrides and other islands west of that group were included under the term Australasia. Of late years these islands (sometimes also including Fiji) have been known as Melanesia, while the western islands of the North Pacific have been known as Micronesia. Thus Polynesia has been restricted to the central and eastern islands inhabited by the brown or Sawaiori race, becoming an ethnographic rather than a geographical term. Articles dealing with the western islands north and south of the equator will be found under MICRONESIA and MELANESIA. The present article is intended to give a comprehensive view of all the islands of the Pacific, their physical characteristics, natural productions, and the races of men found upon them. The name Polynesia is therefore here employed in a wide signification and solely as a geo-

¹ From the scholiast on Apoll. Rh., i. 925, it would appear that Polyhistor was a Milesian only by education, for here the Carian Chersonese is named as his birthplace. The dates seem to show that he was not a personal disciple of Crates.

graphical term. The western boundary of this region runs from the great barrier reef of Australia eastward of New Guinea and the Philippine Islands. All the intertropical islands of the Pacific eastward of this imaginary line are included, and also a few others which extend outside the tropic of Capricorn to nearly 30° S. lat. Any other divisions for geographical purposes, except those of groups of islands, appear to be unnatural and uncalled for. For ethnographical purposes special terms are used for the three different classes of people found in this wide area.

If we exclude NEW CALEDONIA (*q.v.*), which is of older formation than the rest, all the islands of Polynesia are either of volcanic or of coral formation. Some are purely coral, either in the shape of low atolls or of elevated plateaus. In a few atolls there are remnants of earlier volcanic rocks; and most of the volcanic islands are more or less fringed with coral reefs. But, notwithstanding this mixture, the islands must be divided broadly into those which are volcanic and those which are of coral formation. The coral islands must again be subdivided into (1) atolls, or low islands which usually have a lagoon within them, and (2) elevated table-lands.

The volcanic islands, with the exception of the Hawaiian archipelago, are all south of the equator. In plate III. the great volcanic ridge is indicated by two lines which, commencing in 150° E., run in a southeasterly direction to about 140° W. long. With the exception of two curves, one in the lower line south of the New Hebrides, and one in the upper line at its eastern extremity, these are parallel, and are 10° apart. Within these two lines lie all the volcanic islands of Polynesia, except two isolated groups, viz., the Marquesas and the Hawaiian Islands. On this ridge there are no atolls. The upper boundary line sharply divides the volcanic ridge from the atoll valley. This valley is indicated by a third line running for more than 50° of longitude parallel with the other two, at 20° distance from that bounding the northern extremity of the volcanic ridge. Eastward of 155° W. long. this line bends towards the south to exclude the isolated volcanic centre of the Marquesas Islands; then, curving around the Tuamotu archipelago, it joins the central line. Within the area thus enclosed lie all the atolls or low coral lagoon islands of Polynesia, and there are no volcanic islands within this region except in three or four instances, where are found the remnants of former islands which have sunk, but have not been quite submerged. This is the region of subsidence—stretching across fully 100° of longitude, and covering generally about 20° of latitude.

Within the volcanic region there are a few coral islands, but these are all more or less elevated. Since their formation they have participated in the upward movement of the ridge on which they are situated. They are indicated on the map by dotted lines. Two of the groups are within the lines marking the volcanic ridge; and one, the Loyalty group, lies close to the lower line.

The Volcanic Islands.—Most of the volcanic islands of Polynesia are high in proportion to their size. The tapering peaks, or truncated cones, which form their backbone present a picturesque appearance to the voyager as he approaches them. In some there are precipitous spurs jutting into the sea, while in others the land slopes gently from the central peak to the shore. Where there are these gentle slopes, and wherever there is any low land near the shore, there also will be found a coral reef fringing the coast at a smaller or greater distance, according to the steepness of the land under the water. Where the trend downwards is very gradual, the edge of the reef will sometimes be one, two, or even three miles to seaward. It has been thought that the absence of extensive reefs in some islands of the New Hebrides is due to "subterranean heat." But the steepness of the slope of the islands under water is doubtless the reason why the reefs are

small. As the reef-building coral polypes do not live and work below a certain depth—about 20 fathoms, or 120 feet—we easily see that the distance of the outer edge of the reef must be according to the slope of the island beneath the water. Opposite to the larger valleys, where there is a stream flowing out to sea, there is usually found a break in the reef. This is doubtless caused either by the fresh water, or by the sediment which it contains, injuring the coral polypes and preventing them from effectively carrying on their work in these spots. The conviction of the present writer is that it is the sediment contained in the water—especially during heavy rains and consequent freshets—which prevents the growth of the coral, rather than the mere action of fresh water upon the polypés. Where there are streams of considerable size, and especially where they are subject to floods, there are generally wide openings into the reef, and stretches of deep water forming natural harbors sufficient for the accommodation of even large vessels. There are a few landlocked harbors, but most are thus formed by breaks in the reef.

In a few spots active volcanoes are still found. These are in the neighborhood of New Britain and New Ireland, in the Solomon, New Hebrides, and Tonga archipelagoes. In most of the islands there have been no recent eruptions; but now and again the inhabitants of islands where volcanic action has apparently long ceased have been startled by a new outbreak. Over the whole region earthquakes are of frequent occurrence. Most of the craters in the islands of Samoa have immense trees growing in them, and there is only one crater in the entire group which shows signs of even a comparatively recent eruption, or concerning which there is a tradition among the people of one. Yet in 1867, after an almost continuous succession of earthquakes during a whole night, there was a submarine eruption between two of the islands. This lasted only a few days. A few months afterwards the writer was on board H.M.S. "Falcon" when soundings were taken on the spot. A cone was found the summit of which was 90 fathoms deep, while all around the sea was 120 fathoms deep. Thus the outpourings of this submarine volcano during only a few days raised a mound in the bed of the ocean 180 feet in height.

The soil in the volcanic islands is generally very fertile. The climate is hot and moist in most of them; consequently the vegetation is wonderfully rich. The islands are densely clothed with the most luxurious verdure from the sea-beach to the summits of the mountains. While in a few islands, especially the comparatively barren ones (barren is only a comparative term as applied to any of the volcanic islands), there is sometimes grand and bold scenery, in most of them the jagged and precipitous rocks are so covered up and rounded off with the rich vegetation that they lose much of their grandeur. The atmosphere is so laden with moisture that ferns, club-mosses, and even small shrubs grow upon the faces of the steepest rocks. Mainly on this account the scenery can rarely be said to be grand; but nearly all these islands are truly beautiful. There is a freshness about the vegetation all the year round which is rarely seen in other portions of the world. The cocoa-nut palm groves, which are usually abundant on the low lands near the sea, always give a charm to the islands as they are approached. In addition to several species of palms, beautiful ferns, dracænas, crotons, and other elegant foliage plants abound. Pines are found on some of the western islands. For flowers none of them will compare with the hedgerows and meadows of England. There are, it is true, many most beautiful and sweet-scented flowers, but they are not usually found in great profusion.

Fruits are abundant. Some of the indigenous kinds are good, and many of the best productions of other tropical countries have been introduced and flourish.

Oranges are very plentiful in many islands; also pine-apples, guavas, custard apples, and bananas. The mango has been introduced into some islands, and flourishes well. Most of these fruits have been introduced by missionaries. One of the fruits most abundantly used, both in a ripe state and cooked when unripe as a vegetable, is the Chinese banana, *Musa Cavendishii*. The first plant of this carried to the islands was in a case of plants given by the duke of Devonshire to the missionary John Williams when he returned from England to the Pacific shortly before he was killed on Erromanga. During the long voyage all the plants in the case died except this banana. When it reached Samoa it was carefully cultivated by one of the missionaries and a stock of it was propagated. From the single plant all the Chinese bananas in Polynesia have sprung, and, that particular kind being greatly prized both by natives and foreign settlers, it is now grown largely wherever missionaries or traders have gone, and must produce annually hundreds of tons of nutritious fruit.

The natives live chiefly upon vegetable food. In most of the volcanic islands the taro (*Colocasia esculenta*) is the most important food-producer. Next to this comes the yam (*Dioscorea sativa*). Probably next in importance to this are the plantains and bananas, then the bread-fruit (*Artocarpus incisa*) and arrowroot (*Tacca pinnatifida*). The bread-fruit is more or less plentiful in most of the volcanic islands, and during one season of the year the natives very largely subsist upon it. It is not, however, by any means so nutritious as the taro or the yam. This vegetable is often spoken of in Britain as if it were a rich fruit, but one would as soon eat a raw potato as a raw bread-fruit. It has been over-estimated by many writers who have visited the Pacific. The present writer has noticed that the Samoans suffered in condition, that sickness among children was very common and the rate of mortality high during the bread-fruit season. Although the raw cocoa-nut is not eaten to any considerable extent by the natives of volcanic islands, this must not be omitted in an enumeration of the principal articles of their food supply, for it enters into the composition of most of their made dishes in the form of expressed juice or oil; the soft half-grown kernel is used as a kind of dessert, and the liquid from it, when the kernel is only half developed, is one of their principal beverages. The *Ava*, or *Kava*, a narcotic drink largely used, is made from the root of a pepper (*Piper methysticum*).

In some islands the cocoa-nut is the chief article of commerce. The fully-grown kernel is cut into slices, dried in the sun, and sold as "copra," from which much of the palm oil of commerce is expressed. On many islands cotton is largely grown, and on a few, especially in the Hawaiian archipelago, sugar cultivation has made considerable progress. Many other vegetable products might be utilized if there were a demand for them. The candle-nut (*Aleurites triloba*) is abundant everywhere near the coast. Coffee has not been grown to any considerable extent. Wild ginger and wild nutmegs are abundant on some of the islands. In some places indigo has been introduced, and has spread so much as to become a nuisance. All the islands have numerous valuable fibre-producing plants belonging to the *Urticeæ* and *Malvaceæ*. But the probability is that, on these hot, moist, and fertile islands, cocoa-nuts, cotton, or sugar will always be the most profitable crops to cultivate for exportation.

The indigenous fauna of Polynesia is poor in mammals but rich in birds. Mammals are represented by rats and bats, the latter including the flying foxes (*Pteropus*). Some say pigs are indigenous, but they were doubtless introduced by early navigators. Horses and cattle have been introduced. They degenerate very rapidly, unless they are continually improved by newly-imported stock. Sheep and goats are introduced into some islands, but sheep do not usually

thrive. Dogs are plentiful, being kept by most of the natives, who are naturally fond of domestic animals; but they degenerate greatly. Pigeons and doves, especially the fruit-eating pigeons (*Carpophaga*) and doves of the genus *Ptilonopus*, are abundant. The *Carpophaga* furnish a very important article of food in some of the islands. Some of the species of *Ptilonopus* are exceedingly beautiful. Megapodes are found in a few of the western islands; the kagu (*Rhinocetus jubatus*) has its home on New Caledonia; and in Samoa the *Didunculus strigirostris* has its habitat. This bird is remarkable as being the nearest relative of the extinct dodo. Some time ago it was rarely found, and was becoming extinct. It fed and nested on the ground, and was destroyed by cats and rats after they were introduced. Of late it has changed its habits: it now feeds, nests, and roosts upon trees, and is, in consequence, increasing in numbers. Certain non-venomous snakes are found in many of the islands. Insect life is abundant, and some of the butterflies are very beautiful.

The lagoons formed by the coral reefs around the islands invariably abound in fish, many of them most gorgeous in their coloring,—vying in this respect with the parrots of Australia. Fish form a very important part of the food supply.

One of the most wonderful creatures in the marine fauna of Polynesia is the palolo (*Palola viridis*), an annelid which appears upon the surface of the ocean, near the edge of the coral reef, at certain seasons of the year. The Palolo are from 9 to 18 inches long, and about $\frac{1}{4}$ th of an inch thick. They are eaten by the natives, and are esteemed a great delicacy. They live in the interstices of the coral reef, and are confined to a few localities. About 3 o'clock on the morning following the third quartering of the October moon they invariably appear upon the surface of the water; generally they are in such quantities that they may be taken up by the handful. Soon after the sun rises they begin to break, and by 9 o'clock A. M. they have broken to pieces and disappeared. The morning following the third quarter of the November moon they again appear in the same manner, but usually in smaller quantities. After that they are not again seen until October of the next year. They appear thus to deposit their ova, which is done by the breaking to pieces of the female worms; the males also break in the same manner, the ova being fertilized while floating in the water. Thus the parents are destroyed in propagating their species. The eggs gradually sink down to the reef where they are hatched. The young palolo then live about the reef until the next year, when they repeat the process. Year by year these creatures appear according to lunar time. Yet, in the long run, they keep solar time. This they do by keeping two cycles, one of three years and one of twenty-nine years. In the short cycle there are two intervals of twelve lunations each, and one of thirteen lunations. These thirty-seven lunations bring lunar time somewhat near to solar time. But in the course of twenty-nine years there will be sufficient difference to require the addition of another lunation; the twenty-ninth year is therefore one of thirteen instead of twelve lunations. In this way they do not change their season during an entire century. So certain has been their appearance that in Samoa they have given their name to the spring season, which is vaepalolo, or the time of palolo.¹

The Atolls.—The atolls differ in almost every respect from the islands of volcanic origin. Little that is said of one class would be true of the other. These coral islands are all low, generally not more than 10 or 12 feet above high-water mark. They are simply sand-banks formed by the accumulation of debris washed on to the reefs during strong winds. Hence they are usually in the shape of a narrow band, varying from a few yards to one-third of a mile across, near the outer edge of the reef, with a lagoon in the centre. In some of the smaller atolls the circle of land is almost or entirely complete, but in most of those of larger dimensions there are breaks to leeward, and the sea washes freely over the reef into the lagoon. Where the circle of land is complete the sea-water gains access to the central lagoon through the reef underneath the islands.

¹ For fuller details, see article by the present writer in *Proc. Zool. Soc. of Lond.*, 1875, p. 496.

In some it bubbles up at the rise of the tide in the midst of the lagoons, forming immense natural fountains. This has been observed producing a specially fine effect at Nui in the Ellice group. Some of these atolls are not more than 3 or 4 miles in their greatest length. Others are many miles long. They are not all circular, but are of all conceivable shapes.¹

Two of the atolls known to the present writer are remarkable. The lagoons in them are of fresh water. One of these is Lakena, in the Ellice group, the other Olosenga, or Quiros Island, in 11° 2' S. lat. and 171° W. long. Both are small circular islands, and in both the lagoon is shut off from the sea. Olosenga is less than 4 miles in diameter, the lagoon occupying over 3 miles, leaving a ring of land around it less than half a mile across. In some places the lagoon is at least 6 fathoms deep. This bulk of fresh water cannot, therefore, be the result of drainage. There is much to favor the opinion that both this island and Lakena are situated over the craters of former volcanoes, and that there is submarine connection between them and some of the larger islands situated on the volcanic ridge from which the body of fresh water must come. Olosenga is about 200 miles distant from Samoa. In that group mountain streams sometimes fall into chasms and totally disappear underground. In this way subterranean lakes may be formed in some of the cavities which we may suppose volcanic eruptions to leave. It is not difficult to suppose that there would be subterranean connection between these lakes and an isolated crater 200 miles distant. If so, as the crater participated in the subsidence of the region on the edge of which it is situated, the water would rise in it until, if the supply were sufficient, it there found an outlet. This appears to be what occurs at Olosenga. The lake has never been properly examined and sounded. It is, however, of considerable depth in the centre, where the water is said sometimes to bubble up as if from a great spring, and at low tide it is seen to percolate through the sand on the outer or sea side of the land.

The vegetation of the atolls is extremely poor, not more than about fifty species of plants being found in the Tokelau, Ellice, and Gilbert groups, in all of which groups collections have been made. All the species consist of littoral plants found in the volcanic islands. Most of them have their seeds enveloped in thick husks, which specially fit them for being carried by currents. Doubtless it is in this way that the atolls have received their flora. The cocoa-nut is abundant on most of these islands. This most useful palm will grow on any sandbank in the tropics, and it is benefited by having its roots in soil saturated with sea water. Unlike the natives of volcanic islands, those dwelling on the atolls eat the raw kernel of the nut in large quantities. Indeed that, with fish and the fruit of a screw-pine (*Pandanus*), constitutes the main food supply on some atolls. The people make the pulp of the pandanus into a kind of cake, in appearance much like a quantity of old dates. In some atolls a somewhat elaborate system of cultivation has been adopted, by means of which a coarse kind of taro, banana, the bread-fruit, etc., are grown. These low islands suffer much from drought, and the natural soil is nothing but sand. The people, therefore, form wide trenches by removing the sand until they get within about 2 to 3 feet of the sea-level. Into the trenches they put all the vegetable refuse and manure they can obtain, and, as there is more moisture at this level, those excavated gardens are comparatively fertile. Under the influence of a Christian civilization, which is growing, and by the introduction of new food-producing plants, the condition of the natives is improving; but they still suffer much at times from long-continued seasons of drought.

The fauna of the atolls consists mainly of a few

birds, some lizards, and insects. Fish abound about the reefs, and most of the natives are deep-sea fishermen. In the Ellice Islands the people domesticate frigate-birds. Large numbers of these pets may be seen about the villages. As the birds are accustomed to visit different islands when the wind is favorable, the people send by them small presents (fish-hooks, etc.) to their friends. Christian missionaries also occasionally use them as letter-carriers for communicating with one another.

Elevated Coral Islands.—There are comparatively few of the elevated coral islands in Polynesia, but they are so distinct from both the atolls and the volcanic islands that they need a separate description. They all lie within or near the lines marking off the volcanic ridge upon the map. South of the volcanic ridge there are many coral reefs forming shoals. The elevated coral islands doubtless were once such reefs. Lying within the area of volcanic action, they have participated in the upward movement, and have been raised from shoals to become islands. Some have evidently been lifted by successive stages and apparently by sudden movements. This is clearly seen in the Loyalty Islands. On approaching them one sees high coral cliffs, in appearance much like the chalk cliffs of England, except that they are often some distance inland and not close on the shore. The Island of Maré may be taken as a good type of the class. Here, between the shore and the coral cliffs, there is a tract of level land varying from a few yards to perhaps one-fourth of a mile or more across. On this level tract the people mainly dwell. At the back of this there rises a perpendicular wall of coral, in some places as much as a hundred feet high. The cliff is water-worn, and has in it large caverns, showing that for a long period it was the coast-line. Still farther inland there are two similar though smaller cliffs, indicating that there were three distinct upheavals. These must have been at very long intervals. At present the island is fringed with a coral reef, and if it were now to be lifted from fifty to one hundred feet the present coast-line would form another cliff, while the present coral reef would form another low plot similar to that upon which the people now dwell.

These islands are old enough to have a considerable depth of vegetable soil upon them. The low land between the coast and the first cliff is well stocked with cocoa-nut and other trees. None of the islands can be compared with the volcanic islands for fertility, all having a less rich soil and being much drier; still they are fairly fertile. They suffer sometimes from drought, but are much less seriously affected in this way than the atolls.

The flora of the elevated coral islands is less rich than that of the volcanic islands, but much richer than that of the atolls. The island of Niue may be taken as a fair specimen of this class. Its flora probably contains between 400 and 500 species, nearly all being such as are found on adjacent volcanic islands. The fauna is also much richer than that of the atolls, but poorer than that of the volcanic islands. Birds are numerous. While most of the species are identical with those found in neighboring volcanic islands, there are some interesting local variations well illustrating the modifications which take place from isolation under changed surroundings. In some instances the differences are so great that local forms have been classed not only as varieties but as distinct species.

Climate.—The climate of the islands varies considerably, as may be naturally expected when the wide area covered is remembered, and the vast difference there is between the islands themselves. Some, especially the elevated coral islands, are very healthy for tropical regions. Speaking generally, the average reading of the thermometer over a large extent of Polynesia is about 80° Fahr. It very seldom sinks lower than 60°, and, owing to the small size of most of the islands, and the prevalence of trade-winds

¹ On the formation of atolls and of coral reefs generally, see CORALS, vol. vi. 334, and PACIFIC, vol. xviii. p. 132.

during the greater portion of the year, the heat is always moderated, and rarely becomes intense. Yet, owing to the constant heat and to the humidity of the atmosphere, the climate in the mountainous islands is trying to the European constitution. But in this respect there is a great difference even between groups which, looked at superficially, appear to be similar, and which lie within almost the same parallels of latitude. All the islands eastward from and including Fiji are much more healthy than are those to the west. In the eastern section fever and ague are of rare occurrence; in the western section European missionaries do not find it expedient to remain for long periods on the islands owing to the weakening effects of frequent attacks of these diseases. The most remarkable thing is that natives of the eastern section suffer even more than Europeans when they go to live in the western islands, the mortality among them being very great. Numerous attempts have been made to evangelize the New Hebrides through the agency of natives of the Samoan, Cook, and Society groups; but, owing to the great mortality among the agents, their efforts have failed. Yet these people have lived there under conditions very similar to those they were accustomed to at home, the heat being about the same, and the food similar, as well as the general mode of life. The causes of the difference are as yet unknown. Possibly the explanation will be found in differences of natural drainage. It has often occurred to the present writer, though only as an unverified theory, that the bases of these western islands are, like that of New Caledonia, of older formation, and that the islands are only superficially volcanic. If so this may account for their unhealthiness as compared with the purely volcanic islands within the same parallels of latitude. In comparison with most tropical countries there is little dysentery in Polynesia; but this also is more common in the west than in the east.

The elevated coral islands are always much more healthy than are those of volcanic formation in their immediate neighborhood. They are drier, being always well drained, have much less dense vegetation, and receive the benefit of the trade-winds which blow right across them. They, however, sometimes suffer from drought such as is unknown on the volcanic islands. The atolls may be called—if the term can be applied to tiny islets scattered over the expanse of ocean—the deserts of the Pacific. The soil being almost entirely sand, and the vegetation affording little shade, the heat and glare, especially of those lying close to the equator, are exceedingly trying to European visitors. Being so low—only a few feet above the ocean—there is nothing to attract the clouds, and the rainfall is small. The islands are therefore subject to frequent droughts, which are sometimes of months' duration; and at such times even the fronds of the cocoa-nut palm get a shrivelled appearance, and the trees cease to bear fruit. Sometimes the people suffer greatly during these long-continued droughts, many being starved to death. At best their food supply is confined to cocoanuts, pandanus, fruit, and fish, but in times of drought they are forced to chew the roots of shrubs.

Hurricanes.—A great portion of southern Polynesia is subject to destructive cyclones. The tract over which they pass may be said to be, generally, that of the volcanic chain indicated by the lines on the map, although the northern edge of this region is not so subject to cyclones as the southern portion. A line drawn parallel to the lines of the map, through the middle of the New Hebrides group, and extending south of Fiji, will well represent the centre of the cyclone tract. The hurricane season is from December to April. Some islands are visited by a more or less destructive cyclone nearly every year; Samoa lies on the upper edge of the tract, and gets one, on an average, about every seven or eight years. Although these cyclones are not usually so severe as those which visit the seas of eastern Asia, they are often exceed-

ingly destructive, sweeping almost everything down in their course. They last only a few hours. Heavy seas are raised in the line of progress, and vessels are generally exposed to greater danger when lying at anchor at the ports than when in the open sea. The cyclones are always accompanied by considerable electric disturbances, especially when they are passing away.

Diseases.—Apart from the fever, ague, and dysentery already alluded to, there is comparatively little disease in any portion of Polynesia. The principal purely native diseases are such as affect the skin. A form of elephantiasis prevails more or less on all the damp mountainous islands. Many Europeans are subject to it, especially those who are much exposed to the sun by day and the dews by night. In some of the atolls where the people have little good vegetable food and eat a great quantity of fish, much of it often in a state unfit for food, skin diseases are even more common than in the mountainous islands. There are reputed cases of leprosy in the Gilbert Islands, and that disease is well known to be one of the scourges of the Hawaiian archipelago. Several European diseases have been introduced into the islands,—those which are epidemic usually, at the first visitation, working great havoc among the natives. Many in Europe and America appear to attribute the great mortality which occurs among native races, when an epidemic is introduced among them, to weakness and want of stamina in their constitution; but a more probable explanation is found in the fact that, on the introduction of measles or smallpox, all the inhabitants of an island are suitable subjects, that the population of entire villages are prostrated at once, that there are no doctors or nurses, none even to feed the sick or to give them drink, and not even the most ordinary care is taken by the sufferers themselves to lessen the danger.¹ In some islands, especially the Hawaiian group, syphilis, first imported by Captain Cook's expedition, has wrought great havoc. It spread very rapidly, because, at that time, there was almost promiscuous intercourse between the sexes; and this has been one of the chief causes of the physical deterioration and of the rapid decrease of the natives of Hawaii. The disease has been introduced into other islands in later times through the visits of European and American sailors; but, owing to the influence of Christian teaching, which has in many cases gone first and has produced a change for the better in the relations of the sexes, it has not generally spread.

Races.—There are three different kinds of people inhabiting the islands of Polynesia. The region occupied by each is indicated by one of the colors on Plate III., and in the subjoined table of Indo-Pacific peoples the affinity of these races is exhibited.² It will be seen that there are two broad and very distinct divisions,—the dark and the brown races. The dark people occupy Australia, the Andaman Islands, portions of the Indian archipelago, and western Polynesia, and have more or less remote affinity with the natives of South Africa. The brown people are found in Madagascar, the Indian Archipelago, Formosa, northwestern and eastern Polynesia, together with New Zealand, and are clearly of Asiatic origin.

There are in Polynesia people who belong to both the dark and the light sections of the Indo-Pacific races. At present the dark are found only in the western islands as far as Fiji. In some islands they are considerably mixed with the lighter race, and in many places within the region occupied by them are colonies of the light people who keep themselves distinct. For this dark race the name Papuan is here used. They have generally been known of late

¹ In these warm islands the people are generally accustomed to bathe often. When measles prevailed in Fiji many of those who were in a high fever crawled to the bathing places to cool themselves, and many died there. The present writer once visited several islands of the Ellice group about a fortnight after a trading vessel from Sydney, which had influenza on board. This vessel had taken some of the natives from one island to another as passengers, and at three of the islands the entire population was suffering from the epidemic. Had this been a more severe disease the people would have been utterly helpless.

² Compare Mr. Whitmee's paper on this subject in *Journ. Anthropol. Inst. Lond.*, 1879.

years as Melaneseans, but Papuan is an older name which has always been used for part of the race, and which clearly ought to be extended to the whole. The region which they inhabit is colored yellow on the map, and the pink bands across it indicate the presence of some of the light race there.

The whole of eastern Polynesia is inhabited by a light brown people to whom the name Sawaióri is here given.¹ They extend out of Polynesia to New Zealand. They have also formed colonies among the Papuans in various places, and in some instances they have become mixed in blood with the blacks among whom they have settled. The pink color in the map indicates this region.

The third kind of people, here called Tárapon,² inhabit the northern portion of the western Polynesia, the islands generally known as Micronesia (colored green on the map).

The following table shows the relationship of the Indo-Pacific races (Polynesian names in italics):

		Races.	Countries where found.
Indo-Pacific Races of Men.	Dark People: Negrito-Polynesians.	Austral.	Australia.
		Negrito.	Andaman Islands. Samang, etc. Aru Islands.
		Papuan.	Western New Guinea. Solomon Islands, etc. New Hebrides, etc.
			Fiji. Samoa, etc. Hawaii.
	Brown People: Malayo-Polynesians.	Sawaiori.	Cook Islands, etc. Society Islands, etc. New Zealand.
			Madagascar. Formosa.
		Malagasy.	Malays of Sumatra, etc.
		Formosan.	Java, etc.
	Malayan.	Tarapon.	Caroline Islands. Marshall Islands. Gilbert Islands.

I. *The Papuans.*—This name is that used by the Malays of the Indian Archipelago for the black, frizzly-haired people found in the Aru Islands and New Guinea. That the inhabitants of the western portion of Polynesia ought to be classed with these Papuans there can be no doubt. The older name is therefore adopted here to include the whole, rather than the newer and less distinctive name Melanesian which has been applied to only a part of the race. A general description of the people is all that can be given here; for further details the reader is referred to the articles MELANESIA, NEW GUINEA, etc. In speaking of the affinities of the Papuans with other peoples much caution is required; but there is some reason for thinking they may be remotely classified, together with all the other black people of the southern hemisphere, with the tribes of South Africa.³ See NEGRO.

The Papuans are mostly black, but are not of a jet black. In some islands they are lighter than in others. It was long popularly supposed that their hair grew in small tufts. This was, however, a mistake which probably arose from the manner in which many of them are accustomed to dress it. On some islands the men collect their hair into small bunches, and carefully bind each bunch round with fine vegetable fibre from the roots up to within about two inches of the ends. Dr. Turner⁴ gives a good description of this process. He once counted the bunches on a young man's head, and found nearly seven hundred. He calls attention to the resemblance between the head of a Papuan, with his hair thus dressed, and the conventional representation of the hair in Egyptian and Assyrian sculptures, and to what Dr. Livingstone says about the Banyai of South Africa, who

dress their hair in a similar manner. When allowed to grow naturally, the hair of a Papuan is always frizzly. Some of the people have a considerable beard.

In the features of the Papuans there is considerable difference; but in a typical specimen the lips are thick, the nose is broad, often arched and high, and the jaws project; as a rule, the race is prognathous. They are generally small in stature, but in some islands are large. Where, however, they are of large size, we invariably find other evidence of their mixture with another race. Speaking, therefore, of typical Papuans, we may say they are small, with thin limbs, and are physically weak. In their natural condition they are a savage people and are cannibals. They are broken up into hostile tribes, holding no intercourse with one another except by warfare. The languages or dialects spoken by them are very numerous, owing, no doubt, to their hostility towards one another, which has produced complete isolation. In grammatical structure there is considerable resemblance between their languages, but owing to long isolation the verbal differences have become very great. Several different dialects are often found on one island.

Among them women hold a very low position. Nearly all the hard work falls to their share, the men devoting themselves chiefly to warfare. The women cultivate the plantations, carry the burdens, and wait on the men. They take their food from the leavings of the men. Among most of them family life is not greatly elevated above the relationships existing among the lower animals, the relations between the sexes being of the most degraded character. There is, however, considerable affection often manifested towards their children. The Papauns are impulsive and demonstrative in speech and action. They are generally a wild, noisy, boisterous people, easily pleased and as easily offended. They differ so much in different islands, however, that it is extremely difficult to generalize concerning some of their characteristics. Many of them are decidedly low intellectually. On some islands they appear to be physically and intellectually a weak and worn-out race. Yet this must not be understood as applying to all. On some islands youths and men may be seen who are among the brightest and most intelligent-looking people in the Pacific. A vast difference exists between the natives of parts of the New Hebrides and those of the Loyalty Islands, the latter being much the finer. Mixture of blood may partly account for the difference. Difference of physical surroundings, doubtless, also has something to do with it. The dry, comparatively barren, and cooler islands of the Loyalty group ought to have a finer people upon them than the malarious, hot, and moist islands of the New Hebrides. In Fiji some of the finest men in Polynesia are found, but many of the Fijians are considerably mixed with Sawaiiori blood.

As a rule, the Papuans lack elaborate historical traditions, poems, and songs, such as are invariably found among the Sawaiiori race. They do not naturally possess much religious feeling or reverence, and their religious systems are little more than fetishism. In this respect, too, they present a marked contrast to the lighter race. In arts and manufactures they are comparatively low, although there are marked exceptions. Usually their houses are very poor structures. On many islands their canoes are of inferior construction. As a race they are indifferent navigators. Their arms are, however, somewhat elaborately made; and most of them make a coarse kind of pottery. In some parts of the Solomon Islands the people build much better houses than are usually found among the Papuans, carving some of the woodwork rather elaborately. They also build good canoes or boats. In Fiji the natives build good houses and good boats, but there the people have learned some of their arts from the Sawaiioris. It may be so also in the Solomon group. Indeed, throughout the whole of the Papuan region, there is evidence of more or less mixture of the two races. In some places there are pure colonies of Sawaiioris, who keep themselves distinct from their darker-colored neighbors; but in many other places the lighter immigrants have intermarried with the black race.

The following are some broad characteristics of the Papuan languages. Consonants are freely used, some of the consonantal sounds being difficult to represent by Roman characters. Many of the syllables are closed. There does not appear to be any difference between the definite and the indefinite article, except in Fiji. Nouns are

¹ There has hitherto been no one well understood name used for this people. They are generally called "Polynesians" simply, sometimes "Malayo-Polynesians," and recently the name "Mahori" (a vile corruption of "Maori") has been proposed for them. For evident reasons we need some more distinct name than Polynesian. Malayo-Polynesian cannot be confined to them, but must rather be extended to the whole family of which they are but a branch. Sawaiiori is a compound from *sa-moa*, *Ha-wai-i*, and *Ma-ori*, thus derived from the native names of the three principal peoples.

² The name "Micronesians" has been generally adopted. Mr. Horatio Hale, in his great work on the *Ethnography and Philology of the United States. Exploring Expedition*, adopted *Tárawa*—the name of one of the Gilbert Islands, there being no native name for the entire group—for the language of that group. The present writer takes part of this name *Tár-a-wa*, and part of the name of the principal island in the Caroline Islands, viz., *Pon-a-pe*, to form the compound name *Tár-a-pon*.

³ The Rev. R. H. Codrington believes the Papuan (Melanesian) languages belong to the same stock as the rest of the Polynesian languages. But, as is pointed out by Prof. Keane, he entirely overlooks the physical aspects of the question. See *Journ. Anthropol. Soc. Lond.*, 1884.

⁴ *Nineteen Years in Polynesia*, pp. 77, 78; *Samoa*, pp. 308-310.

⁵ No great care is here taken to distinguish between the terms languages and dialects. While all the languages of Polynesia may be included under three classes, we cannot speak of them as three languages, each with numerous dialects any more than we could speak of those languages which have grown out of the Latin as several dialects of one language.

divided into two classes, one of which takes a pronominal suffix, while the other never takes such a suffix. The principle of this division appears to be a near or remote connection between the possessor and the thing possessed. Those things which belong to a person, as the parts of his body, etc., take the pronominal suffix; a thing possessed merely for use would not take it. Thus, in Fijian the word *luve* means either a son or a daughter—one's own child, and it takes the possessive pronoun suffixed, as *luvena*; but the word *ngone*, a child, but not necessarily one's own child, takes the possessive pronoun before it, as *nona ngone*, his child, i.e., his to look after or bring up.¹ Gender is only sexual. Many words are used indiscriminately, as nouns, adjectives, or verbs, without change; but sometimes a noun is indicated by its termination. In most of the languages there are no changes in nouns to form the plural, but an added numeral indicates number. Case is shown by particles, which precede the nouns. Adjectives follow their substantives. Pronouns are numerous, and the personal pronoun includes four numbers—singular, dual, trinal, and general plural, also inclusive and exclusive. Almost any word may be made into a verb by using with it a verbal particle. The differences in the verbal particles in the different languages are very great. In the verbs there are causative, intensive or frequentative, and reciprocal forms.

II. *The Sawaiori Race.*—The brown people who occupy the islands of eastern Polynesia are generally regarded as having affinities with the Malays of the Indian Archipelago, and are sometimes spoken of as a branch of the Malay race, or family. They cannot, however, with any accuracy be so described. The Malays, as they now exist, are a comparatively modern people, who have become what they are by the mixture of several elements not found in the more primitive race. The Sawaioris and the Tarapons of Polynesia, the Malagasy (Hovas) of Madagascar, and the Malays are allied races, but no one of them can be regarded as the parent of the rest. The parent race has disappeared; but the Sawaiori, as the earliest offshoot from it, and one which, owing to the conditions under which it has lived, has remained almost free from admixture of blood, may be taken as most nearly representing what the parent was. The relationship which these Malayo-Polynesian² races bear to one another is seen from the "tree" on Plate III.

The absence of Sanskrit (or Prakrit) roots in the languages appears to indicate that the Sawaiori migration was in pre-Sanskritic times.³ Whether we can fix anything like a definite date for this may well be questioned. Mr. Forander⁴ has, however, with great probability, traced back the history of the Hawaiians to the 5th century. He has studied the folk-lore of those islands exhaustively, and from this source comes to the conclusion that the Sawaiori migration from the Indian Archipelago may be approximately assigned to the close of the first or to the second century. Most likely Samoa was the first group permanently occupied by them. Owing to the admixture of the Sawaioris with the Papuans in Fiji some authorities have thought the first settlement was in those islands, and that the settlers were eventually driven thence by the Papuan occupiers. We can, however, account for the presence of Sawaiori blood in Fiji in another way, viz., by the intercourse that has been kept up between the people of Tonga and Fiji. If the first resting-place of the Sawaioris was in that group, there is good reason to believe that Samoa was the first permanent home of the race, and that from Samoa they have spread to the other islands which they now occupy.

It used to be doubted whether these people could have gone from the Indian Archipelago so far eastward, because the prevailing winds and currents are from the east. But it is now well known that at times there are westerly winds in the region over which they would have to travel, and that there would be no insuperable difficulties in the way of such a voyage. The Sawaioris are invariably navigators. There is ample evidence that in early times they were much better seamen than they are at present. Indeed their skill in navigation has greatly declined since they have become known to Europeans. They used to construct decked vessels capable of carrying one or two hundred persons, with water and stores sufficient for a voyage of some weeks' duration. These vessels were made

of planks well fitted and sewn together, the joints being calked and pitched.⁵ It is only in recent times that the construction of such vessels has ceased. The people had a knowledge of the stars, of the rising and setting of the constellations at different seasons of the year. By this means they determined the favorable season for making a voyage and directed their course.

The ancestors of the Sawaioris were by no means a savage people when they entered the Pacific. Indeed their elaborate historical legends show that they possessed a considerable amount of civilization. Those who are familiar with these legends, and who have studied Sawaiori manners and customs see many unmistakable proofs that they carried with them, at the time of their migration, knowledge and culture which raised them much above the status of savages, and that during their residence in these islands the race has greatly deteriorated. Some indications of their former condition will appear in the following account of the people.

The Sawaioris are, physically, a very fine race. On some islands they average 5 feet 10 inches in height. De Quatrefages, in a table giving the stature of different races of men,⁶ puts the natives of Samoa and Tonga as the largest people in the world. He gives the average height of this race as being 5 feet 9.92 inches. They are well developed in proportion to their height. Their color is a brown, lighter or darker generally according to the amount of their exposure to the sun—being darker on some of the atolls where the people spend much time in fishing, and among fishermen on the volcanic islands, and lighter among women, chiefs, and others less exposed than the bulk of the people. Their hair is black and straight; but in individual examples it is sometimes wavy, or shows a tendency to curl. They have very little beard. Their features are generally fairly regular; eyes invariably black, and in some persons oblique; jaws not projecting, except in a few instances; lips of medium thickness; noses generally short, but rather wide at the bases. Their foreheads are fairly high, but rather narrow. When they are young many of the people of both sexes are good-looking. The men often have more regular features than the women. In former times more attention was paid to personal appearance and adornment among men than among the women.

As a race the Sawaioris are somewhat apathetic. They differ, however, in different islands, according to their surroundings. Most of them live in an enervating climate where nature is very lavish of her gifts. Hence they lead easy lives. On the more barren islands, and on those more distant from the equator, the natives have much more energy. Under certain circumstances they become excitable, and manifest a kind of care-for-nothing spirit. This is only occasionally seen, and chiefly in time of war, in a family dispute, or on some other occasion when they are deeply moved. In the time of their heathenism they were strict in their religious observances, and religion came into almost every action of life. They were in most instances, with comparative ease led to accept Christianity, and this characteristic has remained under the new condition of things. They are a shrewd people, with quick intelligence, and they possess naturally a large amount of common sense. Where they have from early years enjoyed the advantages of a good education, Sawaiori youths have proved themselves to possess intellectual powers of no mean order. They are almost invariably fluent speakers; with many of them oratory seems to be a natural gift; it is also carefully cultivated. A Sawaiori orator will hold the interest of his hearers for hours together at a political gathering, and in his speech he will bring in historical allusions and precedents, and will make apt quotations from ancient legends in a manner which would do credit to the best parliamentary orators. Many of them are very brave, and think little of self-sacrifice for others where duty or family honor is concerned.⁷

⁵ Cocoa-nut fibre and the gum which exudes from the bread-fruit tree are generally used for "calking" and "pitching" canoes.

⁶ *The Human Species* (International Scientific Series), pp. 57-60.

⁷ Of various acts by Sawaioris which indicate the possession of bravery and self-possession under trying circumstances the following may serve as a sample. Some lads belonging to two villages in Samoa fell out, and began stone-throwing. One of them, who was the son of a chief, was struck and, it was feared, was killed. As soon as this was known to the young men of the village they armed themselves in order to go to the other village to seek reparation, according to a custom of former times, by killing some one belonging to the family of the boy who had thrown the stone. A report preceded them that they were going, and a young man, a cousin of the boy, in order to prevent a fight, quietly walked out of the village to meet the avengers of blood. When he met them he calmly said, "You are coming to avenge your brother. I am brother to the boy who killed him. Do not go further; kill me and be avenged, so that our villages may

¹ Hazlewood's *Fijian Grammar*, pp. 8 and 9.

² Baron W. von Humboldt's name, Malayo-Polynesian, is here retained as a convenient term to include all these people from Madagascar to Polynesia.

³ It is possible to make too much of the absence of Sanskrit (or Prakrit) roots, since, as remarked by Dr. Rost, "there may have been no occasion for the introduction of ready-made terms into the language." Still the migration may be tentatively put in pre-Sanskritic times.

⁴ *The Polynesian Race*, vol. i. p. 168.

The terms for family among this race are used in two senses—(1) of a household, and (2) of all blood relations on both the male and the female side, including the wife or the husband, as the case may be, brought in by marriage—also those who have been adopted by members of the clan. In the following remarks the word *family* is used with the first meaning, and *clan* with the second. Each clan has a name which is usually borne by one of the oldest members, who is the chief or head for the time being. This clan system no doubt generally prevailed in early times, and was the origin of the principal chieftainships. But changes have been made in most of the islands. In some the head of one clan has become king over several. In many cases large clans have been divided into sections under secondary heads, and have even been subdivided. The different classes of chieftainships may probably be thus accounted for.

As a rule, near relations do not intermarry. In some islands this rule is rigidly adhered to. There have been exceptions, however, especially in the case of high chiefs; but usually great care is taken to prevent the union of those within the prescribed limits of consanguinity. Children generally dwell with their kin on the father's side, but they have equal rights on the mother's side, and sometimes they take up their abode with their mother's family. The only names used to express particular relationships are father and mother, son and daughter, brother and sister.

There is usually no distinction between brothers (or sisters) and cousins, all the children of brothers and sisters speak of each other as brothers and sisters, and they call uncles and aunts fathers and mothers. Above the relationship of parents all are simply ancestors, no term being used for grandfather which would not equally apply to any more remote male ancestor. In the same way there is no distinctive term for grandchild. A man speaks of his grandchild as his son or daughter, or simply as his child.¹ Polygamy was often practiced, especially by chiefs, and also concubinage. In some places a widow was taken by the brother of her deceased husband, or, failing the brother, by some other relative of the deceased, as an additional wife. Divorce was an easy matter, and of frequent occurrence; but, as a rule, a divorced wife would not marry again without the consent of her former husband. An adulterer was always liable to be killed by the aggrieved husband, or by some member of his clan. If the culprit himself could not be reached, any member of the clan was liable to suffer in his stead. In some islands female virtue was highly regarded. Perhaps of all the groups Samoa stood highest in this respect. There was a special ordeal through which a bride passed to prove her virginity, and a proof of her immorality brought disgrace upon all her relatives. But in other islands there was much freedom in the relations of the sexes. Owing to the almost promiscuous intercourse which prevailed among a portion of the race, in some groups titles descended through the mother and not through the father. In Hawaii there was a peculiar system of marriage relationship, "brothers with their wives, and sisters with their husbands, possessing each other in common." There also, especially in the case of chiefs and chieftainesses, brothers and sisters sometimes intermarried. But these customs did not prevail in other groups. It is almost certain that they did not prevail in Hawaii in early times, but that they were the result of that deterioration in the race which their traditions and many of their customs indicate.²

remain at peace." His conduct somewhat disconcerted the party, and by the timely arrival of a Christian teacher matters were settled without bloodshed.

¹ Dr. Lewis H. Morgan in *Ancient Society*, pp. 419-423, makes the Sawaioris to have distinctive terms for grandfather, grand-mother, grandson, and granddaughter. In this he is entirely mistaken. It is evident from his own lists that the Hawaiian *kupuna* means simply an ancestor. In like manner *moopuna* simply means a descendant of any generation after the first.

² Morgan has founded one of his forms of family—the consanguine—on the supposed existence in former times among the Malays and Polynesians of the custom of "intermarriage of brothers and sisters, own and collateral, in a group." All the evidence he finds in support of this is (1) the existence of the custom above mentioned in Hawaii, and (2) the absence of special terms for the relationship of uncle, aunt, and cousin, this indicating, he thinks, that these were regarded as fathers, mothers, brothers, and sisters. He admits that "the usages with respect to marriage which prevailed when the system was formed may not prevail at the present time." But he adds, "To sustain the deduction it is not necessary that they should" (*Ancient Society*, p. 408). Morgan has given special terms for grandfather and grandmother, because it would prove too much to show that the people had no grandfathers, etc. But these terms are used for ancestors of any generation. The terms used for grandchildren, in like manner, are used for any generation of descendants. He says (p. 406) the terms of husband and wife are used in common by a group of sisters or brothers, but the fact is that the words

Women have always occupied a relatively high position among the Sawaioris. In most groups they have great influence and are treated with much respect. In some cases they take hereditary titles and hold high offices. As among their congeners in Madagascar, so also in parts of Polynesia, there may be a queen or a chieftainess in her own right; and a woman in high position will command as much respect, and will exercise as great authority, as a man would in the same position. Everywhere infanticide prevailed; in some of the smaller islands it was regulated by law in order to prevent over-population. It was also a very common practice to destroy the fetus, yet, even before the reception of Christianity, parents were affectionate towards the children who were spared. The practice of adopting children was, and still is, common. Often there is an exchange made between members of the same clan; but sometimes there is adoption from without. Tattooing generally prevailed among the men, different patterns being followed in different groups of islands. In some a larger portion of the body is tattooed than in others. A youth was considered to be in his minority until he was tattooed, and in former times he would have no chance of marrying until he had, by submitting to this process, proved himself to be a man. Puberty in the other sex was generally marked by feasting, or some other demonstration, among the female friends. Old age is generally honored. Often an inferior chief will give up his title to a younger man, yet he himself will lose but little by so doing. The neglect of aged persons is extremely rare.

Property belonging to a clan is held in common. Each clan usually possesses land, and over this no one member has an exclusive right, but all have an equal right to use it. The chief or recognized head of the clan or section alone can properly dispose of it or assign its use for a time to an outsider; and even he is expected to obtain the consent of the heads of families before he alienates the property. Thus land is handed down through successive generations under the nominal control of the recognized head of the clan or section for the time being. Changes have been made in many islands in this respect; but there can be little reason to doubt that the joint ownership of property in clans was common among the entire race in former times.

In early times the head of each clan was supreme among his own people, but in all matters he had associated with him the principal men or heads of families in the clan. Their united authority extended over all the members and the possessions of the clan, and they were independent of every other clan. There are in some places vestiges of this primitive state of society still remaining; the transition to a limited or to a despotic monarchy may be traced by means of the ancient legends in some islands, and in others it is a matter of recent history. One clan being more numerous and stronger than another, and its chief being ambitious, it is easy to see how by conquering a neighboring clan he increased the importance of his clan and extended his own power. In some of the islands this transition process has hardly yet developed into an absolute monarchy. We may even see two or three stages of the progress. In one instance a certain clan has the right to nominate the principal chief over an entire district; though it is known as the ruling clan, its rule is mainly confined to this nomination, and to decision for or against war. In all other respects the district enjoys the privilege of self-government. In another case the nominal king over a district, or over an entire island, can be elected only from among the members of a certain clan, the monarchy being elective within that alone; but this king has little authority. In other cases a more despotic monarchy has grown up—the prowess of one man leading to the subjugation of other clans. Even in this case the chiefs or heads of clans sometimes still hold their property and rule over their own people, only rendering a kind of feudal service and paying tribute to the king.

The Sawaioris are exceedingly fond of rank and of titles. Much deference is paid to chiefs and to persons of rank; and special terms are generally employed in addressing these. Every part of a chief's body and all his belongings have names different from those employed for common people. The grade of rank which a person occupies will often be indicated by the language in which he is addressed. Thus, in Samoa there are four different terms for to come: *sau* is for a common man; *maluu mai* is a respectful term for a person without a title; *susu mai* for a titled chief; and *afu mai* for a member of the royal family. In addressing chiefs, or others to whom one wishes to be respectful, the singular number of the personal pronoun is rarely used;

used for husband and wife in Hawaii simply mean male and female. In some islands there are terms used for wife in the most strict sense. The word wife is not used more exclusively among us than among some Sawaiori people.

the dual is employed instead,—the dual of dignity or of respect.

Offices and titles are seldom hereditary in our sense of the term, as descending from father to son. They are rather elective within the limits of the clan, or the division of a clan. A common practice is for the holder of a high title to nominate a successor; and his nomination is generally confirmed by the chiefs, or heads of households, with whom the right of election rests. In ancient times the authority of a high chief or king did not usually extend to any details of government. But in Hawaii there are traditions of a wise king who interested himself in promoting the social well-being of the people, and made good laws for their guidance.¹ Usually all matters affecting a district or an island were settled by the chiefs of the district, while those of a single village were settled by a council consisting of the chiefs and heads of households in the village. In some islands each clan, or each village, would feel itself at liberty to make war on another clan or village, without consulting the views of any higher authority. Indeed the rule was for each clan or district to settle its own affairs. In the case of offences against individuals, either the person injured, or another member of his clan, would avenge the injury done. For most offences there was some generally recognized punishment,—such as death for murder or adultery; but often vengeance would fall upon another person instead of the wrongdoer. In avenging wrong, a member of the village or of the clan to which the offender belonged would serve equally well to satisfy their ideas of justice if the culprit himself could not be easily reached. Sometimes all the members of the family, or of a village, to which a culprit belonged would flee from their homes and take refuge in another village, or seek the protection of a powerful chief. In some places, in cases of crime, the members of the family or village would convey the culprit bound—sometimes even carrying him like a pig that is to be killed—and place him with apologies before those against whom he had transgressed. The ignominy of such a proceeding was generally considered sufficient atonement for the gravest offences. There were slaves in many islands, either persons conquered in war, or those who had been condemned to lose their personal liberty on account of evil conduct.

Pottery was not manufactured by the Sawaioris. When any of them possessed it they obtained it from the Papuans. In most of their manufactures they were, however, in advance of the Papuans. They made use of the vegetable fibres abounding in the islands, the women manufacturing cloth, chiefly from the bark of the paper mulberry (*Morus papyrifera*), but also in some islands from the bark of the bread-fruit tree, and the hibiscus. This in former times furnished them with most of their clothing. They also made various kinds of mats, baskets, and fans from the leaves of the pandanus, the bark of the hibiscus, from species of bômeria or other Urticaceous plants. Some of their mats are very beautifully made, and in some islands they are the most valuable property the people possess. The people also use the various fibre-producing plants for the manufacture of ropes, coarse string, and fine cord, and for making fishing nets. The nets are often very large, and are netted with a needle and mesh as in hand-netting among ourselves. The Sawaioris are rather clever workers in wood. Canoe and house-building are trades usually confined to certain families. The large canoes in which they formerly made long voyages are no longer built, but various kinds of smaller canoes are made, from the commonest, which is simply a hollowed-out tree cut into form, to the finely-shaped one built upon a keel, the joints of the various pieces being nicely fitted, and the whole stitched together with cord made from the husk of cocoa-nuts. Some of the larger canoes are ornamented with rude carving; and in some islands they are somewhat elaborately decorated with inlaid mother of pearl. The houses are generally well and elaborately made, but nearly all the ornamentation is put on the inside of the roof. The Sawaioris manufacture several wooden utensils for household use, such as dishes or deep bowls, "pillows" or head-rests, and stools. They also make wooden gongs, or drums, which they beat as they travel in their boats, in their dances, etc. They used to make wooden fishhooks, clubs, spears, and bows. They still make wooden fish-spears; also carved and inlaid combs. They employ the bamboo for making drums and flutes. Formerly the knives the people used were made of bamboo, which is still sometimes used for that purpose. In the manufacture of these things they employed adzes made of stone, shell, or hard wood, and a wooden drill pointed with stone, shell, or bone. They

made mother-of-pearl fishhooks, and they still use a part of those old hooks—or artificial bait—in combination with steel hooks, the native-made portion being generally shaped like a small fish. For water vessels, etc., they employ gourds and large cocoa-nut shells, in preparing which they put water into them and allow the pulp or the kernel to decay, so that it may be removed without breaking the rind or shell. Their drinking cups are made of half a cocoa-nut shell. Sharks' teeth, shells, and bamboo were formerly generally used as cutting instruments; shaving was done with them, as well as surgical operations. They employ vegetable dyes for painting their bark cloth, calabashes, etc. In some islands they also use a red earth for this purpose. Their cloth is generally ornamented with geometrical patterns. Any drawings of animals, etc., which they make are exceedingly inartistic, and no attempt is made at perspective. Their musical instruments are few and rude—consisting of the drums and flutes already mentioned, and shell trumpets.

The Sawaioris were all polytheists. Without doubt many of their gods are deified men; but it is clear that some are the forces of nature personified, while others appear to represent human passions which have become identified with particular persons who have an existence in their historical myths.² But the conception which they had of Tangaloa (Taaroa and Kanaloa in some islands) is of a higher order. Among the Tahitians he was regarded as "the first and principal god, uncreated, and existing from the beginning, or from the time he emerged from *po*, or the world of darkness."³ "He was said to be the father of all the gods, and creator of all things, yet was scarcely reckoned an object of worship."⁴ Dr. Turner says, "the unrestricted, or unconditioned, may fairly be regarded as the name of this Samoan Jupiter."⁵

The worship of certain of the great gods was common to all the people in a group of islands. Others were gods of villages or of families, while others were gods of individuals. The gods of clans were probably the spirits of the ancestors in their own line. In some islands, when the birth of a child was expected, the aid of the gods of the family was invoked, beginning with the god of the father. The god prayed to at the instant of birth became the god of the child. In other places the name of the child's god was declared when the umbilical cord was severed. The gods were supposed to dwell in various animals, in trees, or even in inanimate objects, as a stone, a shell, etc. In some islands idols bearing more or less resemblance to the human shape were made. But in all cases the material objects were regarded simply as the abodes of the immaterial spirits of the gods.

Their temples were either national, for a single village, or for the god of a family. They were sometimes large stone enclosures (*marae*), sometimes a grove, or a house. The principal priests were a particular order, the priesthood being hereditary. In some cases, however, the father of a family was priest in his own household and presented offerings and prayers to the family god.

There was, in the Society Islands, a privileged class known as the *Areoi*. They were the special devotees of two celibate gods. They were not permitted to have children; any children they possessed when they entered the society, and all children subsequently born to them, were destroyed. The name *Areoi* became the synonym for all kinds of license; the party wandered about from place to place conducting obscene entertainments, and was feasted with the best of all the people possessed. There were seven regular grades among the *Areoi* society, besides an irregular class of attendants.

In some islands human sacrifices were of frequent occurrence; in others they were offered only on very rare and exceptional occasions, when the demand was made by the priests for something specially valuable. The usual offerings to the gods were food. The system of *tapu* or *tabu* common among the Sawaioris was connected with their religious rites. There were two ways by which things might become *tapu*,—(1) by contact with anything belonging to the god, as his visible representation or his priest. Probably it was thought that a portion of the sacred essence of the god, or of a sacred person, was directly communicable to objects which they touched. (2) Things were made *tapu* by being dedicated to the god; and it is this form of *tapu* which is still kept up. If, e.g., any one wishes to preserve his cocoa-nuts from being taken, he will put something upon the trees to indicate that they are sacred or ded-

² The following recent books may be consulted on this subject: Rev. W. W. Gill's *Myths and Songs from the South Pacific*; Dr. Turner's *Samoa*; and Mr. Shortland's *Maori Religion and Mythology*.

icated. They cannot then be used until the *tapu* is removed from them. Disease and death were often connected with the violation of *tapu*, the offended gods thus punishing the offenders. Disease was generally attributed to the anger of the gods. Hence offerings, etc., were made to appease their anger. The first-fruits of a crop were usually dedicated to the gods to prevent them from being angry; and new canoes, fishing-nets, etc., were dedicated by prayers and offerings, in order that the gods might be propitious to their owners in their use.

The Sawaiori people invariably believe in the existence of the spirit of man after the death of the body. Their traditions on the condition of the dead vary considerably in different groups; yet there is a general agreement upon main points. Death is caused by the departure of the spirit from the body. The region of the dead is subterranean. When the spirit leaves the body it is conveyed by waiting spirits to the abode of spirits. In most islands the place of descent is known. It is generally towards the west. In some traditions there is a distinction between chiefs and common people in the spirit world. In others all are much alike in condition. Some traditions indicate a marked distinction between the spirits of warriors and those of others; the former go to a place where they are happy and are immortal, while the latter are devoured by the gods and are annihilated. In some, however, the spirits are said to live again after being eaten. Some speak of the abode of spirits as being in darkness; but usually the condition of things is similar to that which exists upon earth. Amongst all the people it is believed that the spirits of the dead are able to revisit the scenes of their earthly life. The visits are generally made in the night, and are often greatly dreaded, especially when there may be any supposed reason for spite on the part of the dead towards living relatives. Some writers have connected cannibalism, where it existed among the Sawaioris, with religious customs. In the Cook and Society Islands, when a human being was offered as a sacrifice, the priest presented an eye of the victim to the king, who either ate it or pretended to do so. Probably the earliest human sacrifices were the bodies of enemies slain in battle. As it was supposed by some that the spirits of the dead were eaten by the gods, the bodies of those slain in battle may have been eaten by their victors in triumph. Mr. Shortland appears to think that cannibalism among the Maories of New Zealand may have thus originated.¹ Among the Sawaioris generally it appears to have been the practice at times to eat a portion of a slain enemy to make his degradation the greater. In several groups there is evidence that this was done. But where cannibalism was practiced as a means of subsistence, it probably originated in times of actual want, such as may have occurred during the long voyages of the people, when it was resorted to as a means of self-preservation. Being once accustomed to the practice we can easily imagine how they might resort to it again and again in times of scarcity. The testimony of cannibals is that human flesh is the best of food, and among such a people there would not be strong moral reasons to restrain them from the indulgence.

The amusements of these people are very numerous. They are a light-hearted race, usually living under easy conditions of life, and they have a large amount of enjoyment. Some of their amusements are boisterous and even savage, such as wrestling and boxing. In some islands they have a kind of "hockey" and foot-ball. They have running races, walking matches, and canoe racing. One of their most exciting amusements is swimming in the surf. When there is a moderate sea on, great numbers often join in this exercise and find immense pleasure in it. Throwing the javelin, throwing at a mark with slings, and archery are also practiced. Some resort to cock-fighting. There are fishing matches; and at a particular season large companies used to resort to pigeon-catching. In their houses they have a number of games. Betting is very often carried on in connection with these. Much time is spent, especially after the evening meal, in asking riddles, in rhyming, etc. The recital of songs and myths is also a source of great amusement; and on special occasions there is dancing. The night dances were generally accompanied by much indecency and immorality, and for that reason were discontinued on the introduction of Christianity.

III. *The Tarapon Race.*—These people have many points of resemblance to the Sawaioris, but, as a rule, they are of smaller stature and are less robust. They have straight black hair, which is more lank than that of the Sawaioris. The Tarapons, however, differ considerably from one another, and are evidently a mixed race. The natives of the Caroline Islands are larger than the Gilbert Islanders. They are also much lighter in color; they are more yellow,

whereas the Gilbert Islanders are darker, than the Sawaioris. In many respects the Tarapons bear a much closer resemblance to the people of some portions of the Indian Archipelago than do the Sawaioris. It is the belief of the present writer that the bulk of the Tarapons are the descendants of people who, in comparatively recent times, migrated from the Indian Archipelago, and that since they have been in Polynesia they have become mixed with people of other races. There appears to be a little Papuan admixture. Those in the Caroline Islands, especially, appear to have become mixed with Chinese and Japanese blood—probably more Japanese than Chinese. There are several well-authenticated instances of Japanese junks, with living people in them, having been found in various parts of the North Pacific. In 1814 the British brig "Forester" met with one off the coast of California (about 30° N. lat.), with three living men and fourteen dead bodies on board. In December, 1832, a Japanese junk arrived at the Hawaiian Islands with four of the crew living. If these junks could cross the Pacific in the latitude of Hawaii, it is not at all unlikely that others running in a southeasterly direction would reach some of the many atolls which stretch over about 35° of longitude, forming the Caroline and Marshall archipelagoes.

The traditions of the Gilbert Islanders tell us that their Islands were peopled from the west and also from the east. Those who came from the east are expressly said to be from Samoa. Those from the west were more numerous than those from the east. There are also traditions of the arrival of other strangers at some of these islands. When the present writer was at the Island of Peru, in the Gilbert group, in 1869, there were still there the remnants of a large proah which, from the description given, appears to have been like those used in the Indian Archipelago. So far as we have materials for examination, craniometry confirms other evidence, and indicates that the Tarapon people are more mixed than either of the other Polynesian races.

All the Tarapon people are navigators, but, owing to the fact that upon their atolls they have little good timber, most of their canoes are inferior to those of the Sawaioris. Their houses are also inferior. Their arms are fairly well made. In the Gilbert Islands they manufacture elaborate armor, to cover the entire body, from the fibre of the cocoa-nut husk. In the Caroline Islands very fine mats are made; and a hand-loom is used, with which a coarse cloth is made.

Among the Tarapons women occupy a lower position than among the Sawaioris. The difference is not, however, in the amount of work, or kind of drudgery that is expected from them, but rather in the social and domestic influence they exert. The gods are chiefly the spirits of the great men of past ages. The chieftainship and priesthood are often combined in the same persons. They are strict in the observance of their religious rites. The shrines of their gods are very numerous. In every house he visited in the Gilbert Islands, the present writer saw either a small circle or a square formed with pieces of coral or shells; this was neatly covered with broken coral and shells from the beach, and in the centre stood a block of coral representing the god. These were the household shrines. In various places about the islands there were similar squares or circles, only larger, for the gods of villages or districts. Offerings of food were presented to them, and often the stones were garlanded with wreaths of cocoa-nut leaves. Some embalm their dead—especially the bodies of beloved children. Women often carry the skulls of deceased children, hung by a cord around the neck, as a token of affection.

In the Tarapon languages consonants are more freely used than in the Sawaiori. They have consonantal sounds which are not found in the latter, such as *ch*, *dj*, and *sh*. Closed syllables often occur; occasionally doubled consonants are used, but among some of the people there is a tendency to introduce a slight vowel sound between them. Most words take the accent on the penult. In some languages there appears to be no true article: but in the Gilbert Island language the Sawaiori *te* is used for both the definite and the indefinite article. Gender is sexual only. Number in the noun is either gathered from the requirement of the sense, or is marked by pronominal words, or numerals. Case is known by the position of the noun in the sentence, or by prepositions. In the language of Ebon, one of the islands in the Marshall archipelago, nouns have the peculiarity which is characteristic of the Papuan languages; those which indicate close relationship—as of a son to a father, or of the members of a person's body—take a pronominal suffix which gives them the appearance of inflections. The present writer is not aware of the existence of this in any other Tarapon language, but would not make too much of this negative evidence. Many words are used indiscriminately as nouns, adjectives, or verbs without any change of form. In some languages the per-

¹ *Maori Religion and Mythology*, p. 26.

sonal pronouns are singular, dual, and plural. In others there are no special dual forms, but the numeral for two is used to indicate the dual. In the Ebon language there are inclusive and exclusive forms of the personal pronouns which, so far as has been ascertained, do not occur in any of the other Tarapona languages. The verbs usually have no inflections to express relations of voice, mood, tense, number of person,—such distinctions being indicated by particles. In the Ebon language, however, the tenses are sometimes marked; but in that the simple form of the verb is frequently given. All have verbal directive particles. In Ponape, one of the Caroline Islands, many words of ceremony are used in addressing chiefs, as they are used in Samoa. The custom of tabooing words is also found there as it is in the Sawaiori language. For further particulars respecting the Tarapona, see MICRONESIA.

Missions.—The first mission was commenced in Tahiti by the agents of the London Missionary Society in 1797. Since then that society has continued and extended its labors until it now occupies the Society, Cook, Austral, Tuamotu, Samoan, Tokelauan, and Ellice groups, and several isolated islands, all peopled by the Sawaiori race, besides other islands in the Papuan and Tarapona areas. With the exception of a portion of the Tuamotu archipelago, all the people in the groups mentioned are now nominal Christians. There are only three groups peopled by the Sawaioris where the London Missionary Society's agents do not labor; and two of these are efficiently occupied by other societies—Hawaii mainly by the American Board, and Tonga by the Wesleyan Missionary Society. These two groups are also entirely Christian. The Marquesas Islands have not been Christianized, but are partly occupied by missionaries from Hawaii. There are, therefore, only two groups peopled by the Sawaioris where any heathen are found at the present day. An estimate of the number of this people, based upon actual counting in many islands, would be about 179,000, of which number about 161,500 are nominal Christians, leaving about 17,500 still heathen. Of the Papuans a smaller proportion are Christians. In Fiji and Rotuma the great majority of the population have become nominal Christians through the labors of Wesleyan missionaries. The Wesleys have also successfully labored in Duke of York Island, near New Britain. In the Loyalty Islands most of the people have embraced Christianity through the labors of the London Missionary Society's agents,—a part, however, being Roman Catholics. Anetium in the New Hebrides has become wholly Christian through the agency of Presbyterian missions. In a few other islands in the New Hebrides, also in Banks and Santa Cruz groups, small companies of converts have been gathered by the Presbyterian and the Episcopal (Melanesian) missions. The rest of the people in the Papuan area in Polynesia are still savages, and most of them are cannibals. The population of this area may be estimated at about 600,000. Of this number about 130,000 are nominal Christians. Excluding the inhabitants of the Ladrone and Pelew Islands, the Tarapona people may be estimated at about 84,000. The agents of the Hawaiian Board of Missions (taking the place of the American Board, under whose auspices the missionaries first labored in this region) are the most numerous here, occupying portions of the Gilbert, Marshall, and Caroline Islands. Six atolls south of the equator in the Gilbert group are occupied by native missionaries from Samoa in connection with the London Missionary Society. The number of nominal Christians in these groups is about 38,000. The aggregate population of Polynesia may thus be estimated at 863,000, of whom 539,500 are heathen and 323,500 are nominal or baptized Christians. From the records of the various missionary societies it appears that out of this number 69,605, or very nearly one-fifth, are communicants.

In addition to the missionary societies already mentioned, which have done the main work in the evangelization of the Polynesians, there are French Protestant missionaries in Tahiti, and Protestant Episcopal clergymen in Hawaii and Fiji. There are also in many islands French Roman Catholic missionaries; but these have a comparatively small number of adherents.

Wherever the missions have been planted schools have also been established, and the people have received more or less education. On the Christian islands nearly all the people can now read, most can write, and a large proportion are acquainted with the elements of arithmetic. General education, thus far, is much more common on those islands than it is at present in the British Isles. Advanced schools have been founded in connection with some of the missions, and many of the native youths have shown considerable aptitude for some of the higher branches of knowledge. In most of the larger groups colleges for the education of native ministers have long been conducted. In these colleges, in addition to Biblical exegesis and theology, other subjects,

such as history and elementary science, are taught. Many of the European and American missionaries have devoted themselves largely to literary work in the vernacular of the islands where they reside. Next to the translation of the Scriptures and the preparation of lesson books for the common schools, they have either translated works on history, science, etc., or they have written such books as they found the natives to need. In nearly every group occupied by the Sawaiori race there is now a considerable vernacular literature, embracing elementary works on most branches of knowledge. Amongst the other races the literature is of much smaller extent. The entire Bible has been translated into five of the principal Sawaiori languages of Polynesia. The entire New Testament, and a considerable portion of the Old, has been translated into a sixth language, besides smaller portions into others. The American Bible Society has supplied the Bibles for the Hawaiian Islands. Many portions of the Scriptures for other islands have been printed either in the islands or in Australia. Of the number of copies thus circulated no record is easily accessible, but the British and Foreign Bible Society has issued 153,462 entire Bibles or New Testaments in the Samoan, Tahitian, Tongan, Rotongan, and Niuean languages. As among this race one translation serves for an entire group, and in some cases for two or three groups, nearly all the people possess the Scriptures. In no part of the world is the Bible more read than it is by these islanders; and it has not been necessary to give the Scriptures to them without charge in order to induce them to read.

In many islands the pastoral work is now mostly done by native ministers,—the foreign missionaries who remain devoting themselves to superintendence, higher education, and literature. The native pastors are always supported by the voluntary gifts of the people to whom they minister. The people also build their own churches and schools, and meet all the expenses connected with public worship and education, upon the voluntary principle. No portion of Christendom is better supplied with religious instruction than the Christianized islands of Polynesia, and nowhere is there more regard paid by the people generally to Sabbath observance, to public worship, and to other outward duties of religion. Family worship is almost invariably observed.

With all this, too many of the people are religious only in name; and in the neighborhood of ports, where casual visitors usually see and judge the native character, there are some who have added many of the white man's vices to their own. But in estimating the influence of Christianity upon these people we should remember that only about one-fifth of the nominal Christians are communicants. If they be judged fairly, taking into consideration their past history and the short time they have been under Christian influence, the present writer is convinced that the verdict will be favorable as compared with any Christian people in the world. Every one will admit that social, moral, and spiritual reformation are not completed in a generation, but require time to bring them to maturity.

Population—its alleged Decrease.—There is a general notion abroad that in all the islands of Polynesia the native races are rapidly decreasing; and this supposed fact is sometimes attributed to the missionaries. The alleged diminution, however, is a general conclusion from particular premises, and facts drawn from wider observations do not confirm it. The question of the decrease of population in these islands is a wide one, which cannot be fully discussed within the limits of the present article; but a few general observations, and a few particular facts, may help to throw some light upon it. (1) The estimates of population made by the first European or American visitors to Polynesia were far too high. In nearly all islands the people live almost entirely upon the coast; hence it was an error to reckon the inland portions as having a population proportionate to the number of people seen upon the coast. Then, when the visits of foreign ships were a novelty, the people from other districts would crowd to the place where the ships anchored to see them. Thus the population of particular villages was over-estimated. In the last edition of this *Encyclopedia* the population of Samoa is said to be variously estimated at from 160,000 to as few as 38,000. It is now known that even the lowest estimate was somewhat over the actual number.¹ Most of the other groups were also greatly over-estimated. Hence the decrease of population in any of the islands since they have become known is not so great as it is supposed to be. (2) Those who have resided in Polynesia, and who have made observations on the subject, know that previous to the

¹ In *Nature*, for 1876, vol. xiv. pp. 190-91, Mr. Whitmee gave the latest census of Samoa, taken by actual counting, as being 34,265 in 1874. Yet, in his *Australasia*, published in 1879, Mr. A. R. Wallace says the population of these islands "is variously estimated at 35,000 or 60,000."

introduction of Christianity there had been a great decrease in the population of most of the islands. There are numerous evidences that they were formerly much more thickly peopled. Wars, infanticide, human sacrifices, and cannibalism are doubtless among the causes of depopulation. (3) Where the scourge of syphilis had not spread before Christianity was received, and the love of ardent spirits has not corrupted the people, there the population has generally increased. It is found from a record of births and deaths in some parts of Samoa, and from periodical census returns as a result of actual counting from the whole of that group, that, apart from the destruction caused by war, the population there increases at the rate of about 1 per cent. per annum. Although Samoa has suffered more from internecine wars than any other Christian group in Polynesia, there are more natives now living there than when they were first counted in 1843, the number then being 33,901. The increase in Tonga has been 25 per cent. in twenty years.¹ On the island of Niue the increase is more than 3 per cent. per annum. On several other groups there has been increase, though figures are not available. The rapid decline of population in Hawaii is entirely exceptional.

Commerce.—Information on this subject, as far as it is available, is given in the special articles on particular groups. The following is a fair specimen of the kind and extent of the commerce which has grown in Polynesia since Christianity has made the islands safe and profitable places for the residence of traders.² From Cook Islands, containing a population of about 8000, and three atolls which lie north of that group, viz., Tongareva, Rakaanga, and Manihiki, with a population of about 4000, the exports during 1883 were 150 tons of cotton free from seeds, 50 tons of coffee, 1000 tons of copra, 84 tons of pearl shell, and about 100,000 gallons of lime juice, besides 5000 crates of oranges, containing about 300 per crate. Mr. Gill estimates the market value of this produce at £50,000 [\$243,000.]—more than £4 [\$19.44] per head for the native population. Part is purchased by merchants in Tahiti, and part goes to Auckland, New Zealand. There are not many islands whence fruit is exported, although, if there were markets within a few days' sail, a large quantity of fine oranges, pine-apples, and bananas might be provided. In 1878 the figures collected by the present writer relating to the trade in Samoa, Tonga, and several other islands in that neighborhood, showed that the exports averaged annually about £4 each for the entire population, and that the imports were only a little less.

Prehistoric Remains.—The most remarkable of these are on Easter Island, which lies at the southeastern extremity of Polynesia, nearly 2500 miles from South America. This island is of volcanic formation, and is about 11 miles long by 4 miles wide. The present inhabitants belong to the Sawaiori race. Here are found immense platforms built of large cut stones fitted together without cement. They are generally built upon headlands, and on the slope towards the sea. The walls on the sea-side are, in some of the platforms, nearly 30 feet high and from 200 to 300 feet long, by about 30 feet wide. Some of the squared stones are as much as 6 feet long. On the land side of the platforms there is a broad terrace with large stone pedestals upon which once stood colossal stone images carved somewhat into the shape of the human trunk. On some of the platforms there are upwards of a dozen images now thrown from their pedestals and lying in all directions. Their usual height is from 14 to 16 feet, but the largest are 37 feet, while some are only about 4 feet. They are formed from a gray trachytic lava found at the east end of the island. The top of the heads of the images is cut flat to receive round crowns made of a reddish vesicular stuff found at a crater about 8 miles distant from the quarry where the images were cut. A number of these crowns still lie at the crater apparently ready for removal, some of the largest being over 10 feet in diameter. In the atlas illustrating the voyage of La Pérouse a plan of the island is given, with the position of several of the platforms. Two of the images are also represented in a plate. One statue, 8 feet in height and weighing 4 tons, was brought to England, and is now in the British Museum. In one part of the island are the remains of stone houses nearly 100 feet long by about 20 feet wide. These are built in courses of large flat stones fitted together without cement, the walls being about 5 feet thick and over 5 feet high. They are lined on the inside with upright slabs, on which are painted geometrical figures and representations of animals. The roofs are formed by placing slabs so that each course overlaps the lower one until the opening becomes about 5 feet wide, when it is covered with flat slabs

reaching from one side to the other. The lava rocks near the houses are carved into the resemblance of various animals and human faces, forming, probably, a kind of picture writing. Wooden tablets covered with various signs and figures have also been found. The only ancient implement discovered on the island is a kind of stone chisel, but it seems impossible that such large and numerous works could have been executed with such a tool. The present inhabitants of Easter Island know nothing of the construction of these remarkable works; and the entire subject of their existence in this small and remote island is a mystery.

On the island Tonga-tabu, Tonga group, there is a remarkable monument. Two large rectangular blocks of stone, about 40 feet in height, stand perpendicularly, with a large slab lying across from one to the other. On the centre of the horizontal stone is a large stone bowl. The island upon which this monument is found is of coral formation slightly elevated. These immense stones must therefore have been conveyed thither by sea. The present inhabitants know nothing of their history, or of the object which they were intended to serve.

In Ponapé, one of the islands of the Caroline group, there are extensive ruins, the principal being a court about 300 feet in length, the walls of which are formed of basaltic prisms and are about 30 feet in height. Inside, on all four sides, next the wall is a terrace 8 feet high and 12 feet wide. The court is divided into three by low walls, and in the centre of each division there is a covered chamber 14 feet square. The walls above the terrace are 8 feet thick, and some of the stones are 25 feet long by 8 feet in circumference. The basaltic columns of which this structure is built were apparently brought a distance of 10 miles from the central ridge of the island. There are other ruins of smaller extent on Ponapé, and also on the island of Kusaie in the same group. Ponapé and Kusaie are remnants of larger islands which have been partially submerged. While the smaller islands around which the coral polypes built up the atolls have disappeared, these two remain as monuments of the past.

Northwest from Ponapé, in the Mariana or Ladrone Islands, there are other remains in the shape of stone columns about 14 feet high, with a semi-globular stone nearly 6 feet in diameter on the top of each, the rounded side being uppermost.

Thus in four different and widely separated parts of Polynesia there are relics of prehistoric people. These together form one of the greatest puzzles the ethnologist has to deal with. (s. J. W.)

POLYPE. In its Greek and Latin forms the word *polypus* was first used as descriptive of the CUTTLE-FISH (*q.v.*). In speaking of the *Acalephæ* Aristotle says, "They hold their prey as the polypus does with its feelers," and there is no doubt that in this and other passages he referred to the octopus. The word was also, though less generally applied to the woodlouse (*Oniscus*)—the reason for both usages being equally evident. Though the former meaning persists in the word *poulpe*, yet by the beginning of the 18th century it seems to have been forgotten, and the word was by analogy transferred to a group of animals then beginning to attract much attention. Réaumur and Bernard de Jussieu were the first to fix the usage of the word *polype* as applicable to hydroids, corals, and *Polyzoa*. In following up the discoveries of Marsigli and Peysonelle in regard to the little coral organisms, Jussieu used the name *polype* definitely to describe those Sertularians, Alcyonians, sea-mats, etc., which were then (1742) known as animals. Trembley had previously rediscovered Leeuwenhoek's *Hydra*, and described it as a fresh water polype in a work which appeared in 1744. A polyzoon too, discovered both by Trembley and Baker in 1741, was called by the former *Polype à Panache*. We find the word used with the same content as Jussieu had assigned to it by Ellis in 1755, by Cavolini in 1783, and by others. In 1816 Lamouroux published his *Histoire des Polypiers Coralligènes*, in the preface of which he speaks of the varied character of this group of animals "nommés Hydres par Linné et Polypes par Réaumur." In his own use of the term he applied it to sponges, hydroids, corals, and *Flustræ*. Lamarek too used the word very widely, and spoke of *Polypei* as (1) *ciliati*, including some Infusorians and Rotifers; (2) *denudati*

¹ This fact is stated on the authority of the Rev. Mr. Moulton, a missionary residing there, and it is the result of counting.

² From figures supplied by the Rev. W. W. Gill, B. A.

including *Hydra*, *Coryne*, etc.; (3) *vaginati*, including *Diffugia*, *Spongilla*, *Tubularia*, Millepores and Madreporae, *Acyonia*, *Cristatella*, *Flustra*, etc.; and (4) *natantes*, including *Pendatula*, *Virgularia*, *Encrinurus*, etc. Sometimes, however he used the word in a more restricted sense. Cuvier (1819-1830) distinguished three classes of polypes: (1) fleshy—*Actinia* and *Lucernaria*; (2) gelatinous—*Hydra*, *Cristatella*, *Coryne*, *Vorticella*, etc.; and (3) *Corallifera*—Sponges, Madreporae, Millepores, *Tabularia*, *Sertularia*, *Acyonidae*, *Flustrea*, etc. Subsequently he improved on this and recognized (1) *Actinia* group, (2) a group like *Hydra* and *Sertularia*, and (3) *Polypes à Polypiers*, which he again divided into *Anthozoa* and *Bryozoa*. From 1830 onwards there was a distinct tendency to separate the *Polyzoa* from the polypes—they are spoken of as higher *Polypi*, compound polypes, etc. In 1831 Ehrenberg described the *Polypi* or *Coralia* as a class of the *Phytozoa* and distinguished the true polypes or *Anthozoa* from the *Bryozoa*. Milne-Edwards expressly excludes the *Bryozoa*, and restricts the term polype to the *Zoantharia* and *Acyonaria* inclusive of *Hydra* and *Lucernaria*. In 1847 Frey and Leuckart placed the *Polyzoa* by themselves, and united the remaining *Polypi* of Cuvier along with the *Acalephæ* under the class named *Cœlenterata* which the latter afterwards (1853) divided into (1) *Ctenophora*, (2) *Medusæ*, and (3) *Polypes*. Modern anatomists generally agree in confining the term to the individuals (*zooids* or *personæ*) of hydriform *Hydro-medusæ* and *Actinozoa*, and frequently restrict it to the former (see HYDROZOA, CORALS).

POLYPTERUS, a genus of Ganoid fishes common in many rivers of tropical Africa, and known on the Nile by the name of *abū bishir*. Their body is cylindrical in shape, elongate, and covered with hard, polished, ganoid scales, which are arranged in oblique series. The head, with flattened snout and wide mouth is protected by bony plates with ganoid external surface, of which a series of "supra-temporal" and "spiracular" ossicles are especially characteristic. Spiracles, or external openings of a canal leading into the pharynx are persistent throughout life, situated on each side of the parietal bone, and closed by an osseous valve. The lips are fleshy, but the space between the rami of the mandible is covered by a large "gular" plate. The vent is placed far backwards, in front of the anal fin, the tail being short, with a diphyceal termination of the vertebral column. The mouth is well provided with rasp-like teeth, forming broad bands in the jaws, on the vomer and palatine bones. The paired fins are supported by an axial skeleton. The structure of the dorsal fin is unique: its anterior portion is composed of isolated finlets, from eight to eighteen in number, each of which consists of a flattened spine with a bifurcate termination; to the posterior aspect of the top of each spine several soft rays are attached, which result from the dichotomous division of a single ray, the basal portion of which is the spine. Posteriorly these finlets pass into the ordinary rays compos-

ing the caudal fin, which surrounds the tail. The ventral fins are well developed, and inserted behind the middle of the length of the trunk. The respiratory apparatus consists of three and a half gills, and is protected by an osseous gill-cover. An external gill of considerable size in the form of a tapering band fringed with respiratory laminae exists in young examples, and is attached to the end of the gill-cover. The air-bladder is double, and communicates with the ventral wall of the pharynx.

Such are some of the principal characteristics of one of the most interesting representatives of a type which in *Polypterus* has survived from the Devonian and Carboniferous formations to our period; for further details of its internal organization see ICHTHOLOGY. The centre of distribution of *Polypterus* is the lake region of tropical Africa, from which the Nile and the great rivers of West Africa take their origin. A very remarkable fact is its total absence in the East-African river systems which belong to the Indian Ocean. Specimens of the bishir have been found in the Nile as low as Cairo, but it is very scarce throughout the middle and lower parts of that river; such individuals have evidently been carried by the current down from southern latitudes, and do not propagate the species in the northern parts. As mentioned above, the number of the rays which are modified into finlets varies considerably, and consequently several species have been distinguished by some naturalists, while others hold that there is one species of *Polypterus* only. The largest specimens observed had a length of 4 feet. Nothing is known of its habits and propagation, and observations thereon are very desirable. Some years ago an extremely interesting dwarf form of *Polypterus* was discovered in Old Calabar, and described under the name of *Calamoichthys calabaricus*. It much resembles the bishir but is smaller, and considerably more elongate.

POLYPUS, a term in surgery, signifying a tumor which is attached by a narrow neck to the walls of a cavity lined with mucous membrane. A polypus or polypoid tumor may belong to any variety of tumor, either simple or malignant. The most common variety is a polypus of the nose of simple character and easily removed. Polypi are also met with in the ear, larynx, uterus, vagina, and rectum. See SURGERY.

POLYSPERCHON, one of Alexander's generals, and the successor of Antipater as regent in Macedonia in 318 B.C. He was driven from the kingdom by Cassander in 316. For the leading incidents of his brief term of office see PHOCION (vol. xviii. p. 813); compare also MACEDONIA.

POLYXENA, in Greek legend, a daughter of Priam, last king of Troy, and Hecuba. She had been betrothed to Achilles, and after his death and the destruction of Troy the ghost of Achilles appeared to the returning Greeks as they were encamped on the Thracian Chersonese and demanded of them the sacrifice of Polyxena. The Greeks consented and Neoptolemus, son of Achilles, sacrificed Polyxena on his father's grave. This tragic story is the subject of the *Hecuba* of Euripides and the *Troades* of Seneca. Of Sophocles's tragedy *Polyxena* a few fragments only remain.

POLYZOA.

POLYZOA is the name applied by J. Vaughan Thompson in 1830 (1)¹ to a group of minute polyp-like organisms which were subsequently (1834) termed "Bryozoa" by Ehrenberg (2). The forms included in this group were stated by Thompson to be "in a general way the whole of the Flustraceæ, in many of which I have clearly ascertained the animals to be Polyzoæ," they having been previously considered by zoologists to be allied to the Hydra-like

polyps. These organisms had previously been known by the hard corneous "cells" or chambers which are formed by the animals on the surface of their bodies, and build up, in consequence of the formation of dense colonies by budding, complex aggregates known as "sea-mats" and "sea mosses." Thompson expressly stated the opinion that the organization of the animals detected by him led to the conclusion that "they must be considered as a new type of the Mollusca Acephala."

Subsequently (1844) Henri Milne-Edwards (3) pointed out the relationship of Thompson's Polyzoa to

¹ These numbers refer to the bibliography at the end of the article.

the Brachiopoda, and adopting the latter's view as to their Molluscan affinities, proposed to unite these two classes with the Tunicata in a group to be called "Molluscoidea." Recent researches have entirely separated the Tunicata from this association, and have demonstrated that they belong to the great phylum of Vertebrata. On the other hand the association of the Polyzoa with the Brachiopoda appears at present to be confirmed, though the relationship of these two classes to the Mollusca has been shown to rest on mistaken identification of parts; see, however, Harmer (18).

The Polyzoa appear to be related to the Sipunculoid Gephyraean worms (*Gephyraea inermia*) more nearly than to any other class of the animal kingdom. The study and interpretation of the facts of their ontogeny (growth from the egg) presents such extreme difficulty that in the present state of our knowledge it is necessary to regard them *ad interim* as forming with the Brachiopoda and Sipunculoids an isolated group, to which the name "Podaxonia" may be applied, pending the decision of their affinities by the increase of our knowledge of the embryology of important members of the group.¹

The forms included at the present day in Thompson's class of "Polyzoa" may then be thus classified:

PHYLUM PODAXONIA.

CLASS I.—SIPUNCULOIDEA.

CLASS II.—BRACHIOPODA.

CLASS III.—POLYZOA.—

Section 1.—VERMIFORMIA.

Sole genus: *Phoronis* (Figs. 4 and 5).

Section 2.—PTEROBRANCHIA.

Genus 1: *Rhabdopleura* (Fig. 7).

Genus 2: *Cephalodiscus* (Figs. 8, 9, 10).

Section 3.—EUPOLYZOA.

Sub-class 1.—Ectoprocta.

Order 1.—PHYLACTOLÆMA.

Examples: *Lophopus*, *Plumatella* (Fig. 2, B), *Cristatella* (Fig. 3), *Fredericella*.

Order 2.—GYMNOLÆMA.

Sub-order 1.—Cyclostoma.

Examples: *Crisia* (Fig. 13, A), *Hornera Tubulipora*, *Discoporella*.

Sub-order 2.—Ctenostoma.

Examples: *Alcyonidium*, *Vesicularia*, *Serialaria*, *Bowerbankia*, (Fig. 1, A), *Paludicella* (Fig. 1, E and Fig. 2, A).

Sub-order 3.—Chilostoma.

Examples: *Cellularia*, *Scrupocellaria*, *Kinetoskias* (Fig. 14), *Bugula*, *Bicellaria*, *Flustra* (Fig. 1, G), *Mucronella* (Fig. 1, C, D, F), *Membranipora*, *Lepralia*, *Eschara*, *Cellepora*, *Retepora*.

Sub-class 2.—Entoprocta.

Genera: *Pedicellina* (Fig. 15), *Loxosoma* (Fig. 16),

Urnatella, *Ascopodaria*.

We shall most readily arrive at a conception of the essential structure of a Polyzoon, and of the variations to which that essential structure is subject within the class, by first examining one member of the group in detail and subsequently reviewing the characters presented by the divergent sub-classes, orders, etc., above indicated.

The most convenient form for our purpose is *Paludicella Ehrenbergii* (Fig. 2, A), belonging to the typical section of the class (the Eupolyzoa) and to the order Gymnolæma. The organism occurs as minute tree-like growths (Figs. 2, A and 1, E) attached to stones in freshwater streams and canals. The branches of the little tree

 B. A cluster of polypides of *Bowerbankia pustulosa*, some with expanded tentacles; more highly magnified.
 C. Zoecia of *Mucronella pavonella* (Chilostoma); highly magnified.
 D. Zoarium of *Mucronella pavonella*, forming a disk-like encrustation on a piece of stone; natural size.
 E. Zoarium of *Paludicella Ehrenbergii* (Ctenostoma), natural size.
 F. Zoecia of *Mucronella Peachii*; highly magnified. Compare with C in order to note specific characters.
 G. Zoarium of *Flustra securifrons*; natural size.

¹ The research of Harmer (18) on *Loxosoma* is published too late for due notice in this article. It tends to the conclusion that the Eupolyzoa are after all degraded Mollusca, and have no connection with the Vermiformia, Pterobranchia, Brachiopoda, and Sipunculoides. The reader is referred to Mr. Harmer's memoir.

the very numerous joints is about one-fifth of an inch long, and is in reality a tubular horny box attached above and below to the preceding and succeeding joints, and having on one side of it a spoutlike aperture from which a crown of tentacles can be protruded. Each joint is thus inhabited by a distinct

animal which is more or less completely shut off from the one in front of it and the one behind it, although it originated from the hinder and has given rise to the fore-lying individual by a process of budding, and retains a continuity of substance with both. A single cell or joint with its contained animal is represented in Fig. 2, A.

Paludicella produces an arboriform colony, the main trunk or stolon being adherent to some stone or piece of wood. The substance of the wall of the cells is formed by a chemical body allied to chitin. Other Polyzoa may form mat-like expansions—the cells being placed in one plane, side by side (Fig. 1, C, D, F, G), as well as in linear series; others again form solid masses, whilst many agree with Paludicella in the simple linear arrangement of their units. Phoronis and Loxosoma, on the other hand, do not form colonies at all—the former because it does not bud, the latter because the buds become detached from their parent as soon as formed, as do the buds of the Hydrozoan Hydra.

On the whole Paludicella presents us with a very

FIG. 2.—A. Polypide of *Paludicella Ehrenbergii*, seen as a transparent object in optical section and highly magnified (from Gegenbaur, after Allman). For natural size see Fig. 1, E. a, anus; dr, peristomial circllet of ciliated tentacles; t, thickened cuticle of the body-wall, forming the horny cell or zoecium; m, median retractor muscle of the introversible part of the body; mr, anterior retractor of the same; mr, great retractor muscle of the same; o, ovary, passing from which to the stomach is the anterior mesentery or funiculus; t, testis; s, oesophagus; v, stomach; x, posterior mesentery or funiculus; x', anterior mesentery or funiculus. Observe at the right upper corner of the figure the base of a second polypide and the "rosette-plate" of separation.

B. Diagram of a polypide of *Plumatella*. Letters as above.

simple form of Polyzoan-colony (technically termed a "zoarium") in which the aggregate of budded persons, each of which is called a "polypide," does not exhibit any marked individuation, but is irregular and tree-like. But, just as in the Hydrozoa we find the Siphonophora presenting us with a very definite shape and individuality of the aggregate or colony, so in the Polyzoa we find instances of high individuation of the zoarium of a similar kind. The most remarkable example is afforded by the locomotive zoarium or colony

of *Cristatella* (Fig. 3); and another very striking instance is that of the stalked zoaria of *Kinetoskias* (Fig. 14) and *Adeona*.

The horny consistence of the cells which are produced by Paludicella is very usual in other Polyzoa; but we find frequently that the substance which forms the cells is gelatinous and soft instead of being horny, or again may be strongly calcareous. The term *cœnœcium* is applied to the mass of cells belonging to a colony or zoarium when considered apart from the living polypides which form it. Often such *cœnœcia* are found retaining form and structure when the soft living polypides have decomposed and disappeared. A single cell of the *cœnœcium*, corresponding to a single polypide, is called by the special students of the Polyzoa a *zoœcium*.

If we examine a single cell or zoœcium of Paludicella more carefully whilst its polypide is alive, we discover that the horny cell is nothing more than the cuticle of the polypide itself, to which it is absolutely adherent. At the so-called "mouth" or spout of the cell the cuticle suddenly changes its character and becomes a very delicate and soft pellicle instead of being thick and horny. There is no real discontinuity of the cuticle at this region, but merely a change in its qualities. This gives to that portion of the body of the polypide which lies beyond the spout a mobility and capacity for folding and pleating which is entirely denied to that part where the cuticle is more dense (Fig. 2, A). Accordingly we find that the anterior portion of the body of the polypide can be pulled into the hinder part as the finger of a glove may be tucked into the hand. It is, in fact, an "introvert" (for the use of this term see MOLLUSCA, vol. xvi. p. 676). This arrangement is universal in the Ectoproctous Eupolyzoa, but does not obtain either in the Entoprocta, the Pterobranchia, or the Vermiformia. In Phoronis, Rhabdopleura, and Cephalodiscus the anterior part of the body can not be tucked or telescoped into the hinder part as it can in typical Eupolyzoa. On the other hand it is very important to note that the Sipunculoid Gephyræans are all pre-eminently characterized by possessing identically this arrangement. The introversion is effected in Paludicella (as in other Eupolyzoa) by a series of long detached retractor muscles of considerable power (Fig. 2, A, mr, r', m); the same is true of Sipunculus.

The view has been advanced by Allman (4) that the retractile part of the polypide is to be considered as a distinct individual budded from the basal portion, which is regarded as an equivalent individual. It does not appear to the present writer that such a theoretical conception tends to facilitate the understanding of the structure and relations of these animals.

An "ectocyst" and "endocyst" have also been distinguished in former treatises, and these terms form part of a special "polyzoarial" nomenclature, but do not appear to be any longer needful. Equally undesirable is the misapplied term "endosarc" lately introduced by Jolliet (5) to denote a certain portion of the Polyzoan structure which will not be referred to here by that name.

The retractile or introversible portion of the body of the polypide of Paludicella is terminated by a crown of sixteen stiff non-contractile tentacles (Fig. 2, A, br,) which form a circle around a central aperture—the animal's mouth. These tentacles are hollow and beset with vibratile cilia. The beating of the cilia causes a powerful current in the water by which food is brought to the animal's mouth. Each tentacle is also muscular, and can be bent and straightened at will. The tentacles not only serve to bring food into the mouth, but they are efficient as gill-filaments, being possibly homologous with (as well as functionally similar to) the gill-filaments of Lamellibranch Molluscs. They also serve as delicate tactile organs, and are the only sense organs possessed by the Eupolyzoa.

In *Paludicella* the platform around the mouth from which the tentacles arise, or *lophophore*, as it is termed, is circular. This is the case in all members of the large group of *Gymnolæma* and in the *Entoprocta*. But in the *Phylactolæma* the lophophore is drawn out on each side, right and left, so as to present a horse-shoe shape (Fig. 2, B), and in some forms, notably *Lophopus* and *Aleyonella*, the two arms or diverging rami of the horse-shoe are very strongly developed.

In the *Pterobranchia* the tentacles are confined in one genus (*Rhabdopleura*) to the two arm-like outgrowths of the lophophore, and are not simply hollow but contain a well-developed cartilaginous skeleton (Fig. 7). In the allied genus *Cephalodiscus* there are not merely a single pair of such arm-like processes, each bearing two rows of tentacles, but the lophophore is developed into twelve arm-like processes (Fig. 9), which form a dense tuft of filaments around the anterior extremity of the animal.

In the *Vermiformia* (*Phoronis*) we again meet with a very perfect horse-shoe-shaped lophophore (Fig. 4). The tentacles upon the crescentic or otherwise lobed circumoral region of the *Sipunculoids* are the representatives of the tentacles of the *Polyzoa*; whilst the tentaculiferous "arms" of the *Brachiopoda* appear to be the equivalents of the *Polyzoa*'s lophophore much drawn out and in most cases spirally rolled.

Just below the circular crown of tentacles in *Paludicella* we find an aperture which the study of internal anatomy proves to be the anus. In all *Polyzoa* the anus has this position near the mouth; and in this respect we again note an agreement with *Sipunculus* and the other so-called *Gephyræa inermia*. In one division of the *Polyzoa* alone is there any noteworthy variation in the position of the anus, namely, in the *Entoprocta* (sub-class of the section *Eupolyzoa*). In these forms the anus, instead of lying just below the lophophore or platform from which the tentacles spring, is included like the mouth within its area (Fig. 15, C).

Passing now to the deeper structure of *Paludicella*, we find that it is a *Cœlomate* animal; that is to say, there exists between the body-wall and the wall of the alimentary tract a distinct space termed "perigastric space," "body-cavity," or "cœlom." This is true of all *Polyzoa*, though it has been erroneously stated by G. O. Sars that *Rhabdopleura* does not possess such a cœlom. In *Eupolyzoa* (excepting the *Entoprocta*) the cœlom is very capacious; it is occupied by a coagulable hæmolymp in which float cellular corpuscles, and also the generative products, detached, as is usual in *Cœlomata*, from definite "gonads" developed on its lining membrane (Fig. 2, A, o, t). This lining membrane or "cœlomic epithelium" is ciliated in the *Phylactolæma*, but its characters appear not to have been definitely determined in other *Eupolyzoa*. The cœlomic space and the tissues bounding it are continuous throughout the colony or zoarium of a *Polyzoon*—either directly without any constriction marking off one polypide from another, or through perforate septum-like structures as in *Paludicella* (see right-hand upper process of Fig. 2, A), which form incomplete barriers between juxtaposed zoœcia, and are termed "rosette-places" or "communication-plates." The cœlomic cavity is continued in *Paludicella* and probably in all *Polyzoa* into the tentacles, so that these organs expose the hæmolymp fluid to a respiratory action, and hence may be called *branchial*.

The body-wall of *Paludicella* consists, alike in the anterior introversible region, and in the posterior region, of an outer cuticle which has already been spoken of as thickened around the base of the polypide so as to become there the hard tube-like zoœcium. Beneath this is the delicate layer of living epidermic cells which are the mother-cells or matrix of that cuticle. Beneath this again are a few scattered annuli of muscular fibre-cells arranged ring-wise around the cylindrical

body; more deeply placed than these are five large bundles of longitudinally placed muscular fibre-cells which are attached at three different levels to the soft introversible portion of the body, and by their retraction pull it in three folds or telescopic joints into the capacious hinder part of the body. In some *Polyzoa* the muscular fibre-cells present transverse striations. These folds are shown in Fig. 2, A; but when the

FIG. 3.—The locomotive zoarium of the freshwater *Phylactolæmous Polyzoon Cristatella mucedo*; magnified six times linear (after Allman). *a*, individual polypides with their horse-shoe-shaped crown of tentacles exerted; *b*, statoblasts seen through the transparent tissues; *c*, the muscular foot or base of the colony by means of which it crawls; *d*, portion of water-weed upon which the *Cristatella* is crawling.

longitudinal muscles are completely contracted the tentacular crown would be pulled down far out of sight into the midst of the body by the great longitudinal muscle *mr*. Deeper than the longitudinal muscles, and clothing them and everything else which projects into the cœlom, is the cœlomic epithelium, not easily observed, and sufficiently known only in the *Phylactolæma*. Part of it gives rise to the generative products (Fig. 2, A, o, t). Other *Eupolyzoa* have a similar but not identical arrangement of the longitudinal muscles—acting essentially as retractors of the "introvert" or soft anterior region of the body—and a similar structure of the body-wall which is in essential features identical with that of the *Sipunculoid* worms, the *Chætopod* worms, and other typical *Cœlomate* animals.

The alimentary canal of *Paludicella* forms a closely compressed U-shaped loop depending from the closely approximated mouth and anus into the capacious cœlom. It is clothed on its cœlomic surface (in *Phylactolæma* at any rate) with cœlomic epithelium, and beneath this are extremely delicate muscular layers. Within it is lined, except in the immediate region of the mouth (which is lined by the in-pushed outer cell-layer), by the enteric cell-layer—the digestive cells derived from the archenteron of the embryo. We can distinguish in *Paludicella* a contractile pharyngo-œsophagus (Fig. 2, A, æ), a digestive stomach *v* (the lining cells of which have a yellow color), and an intestine which forms that arm of the loop connected with the anus. This simple form of alimentary canal is uniformly present in *Polyzoa*. In *Bowerbankia* and its allies a muscular gizzard with horny teeth is interposed between œsophagus and digestive stomach.

The alimentary canal of *Paludicella* does not hang quite freely in the cœlomic cavity, but, as is usually the case in other classes where the cœlom is large, *mesenteries* are present in the form of fibrous (muscular?) bands clothed with cœlomic epithelium and suspending the gut to the body-wall. In *Paludicella* there are two of these mesenteries, an anterior (*x'*) and a posterior (*x*). The presence of two mesenteric bands is exceptional. Usually in the *Eupolyzoa* we find one such mesentery only, corresponding to the hinder of the two in *Paludicella*. The special name *funiculus* (Huxley) is applied to this mesenteric band, and it is noteworthy that the cells of the cœlomic epithelium,

either upon its surface or at its point of insertion into the body-wall, are modified as reproductive elements, forming either the testis or ovary; in the *Phylactolæma* they form here also special asexual reproductive bodies, the stato-blasts. The nervous tissue and organs of *Paludicella* have not been specially investigated, but in many Eupolyzoa an oval mass of nerve-ganglion cells is found lying between the mouth and anus, and there is no doubt that it is present in this case. In *Plumetella* nerve-fibres have been traced from this ganglion to the tentacles and other parts around the mouth (Fig. 11, *w, x, y*). A "colonial nervous system" was described some years ago by Fr. Müller in *Serialaria*; but modern histologists do not admit that the tissue so named by Müller is nerve-tissue. The ganglion above mentioned is the only nervous tissue at present known in Polyzoa (but see Fig. 17, *x*).

No heart or bloodvessels of any kind exist in *Paludicella* nor in any of the Eupolyzoa or Pterobranchia. On the other hand the isolated vermiform genus *Phoronis* presents a closed contractile system of longitudinal vessels (dorsal and ventral) which contain nucleated corpuscles colored red by hæmoglobin (Figs. 4, 5).

No excretory organs (nephridia) or genital ducts have been observed in *Paludicella*, nor have such organs been detected in the majority of the Polyzoa which have been studied. In the Entoprocta, however, a pair of minute ciliated canals are found in the nearly obliterated body-cavity opening to the exterior near the tentacular crown in both *Pedicellina* and *Loxosoma*, which represent the cephalic nephridia of worms. A definite pair of nephridia occur in *Phoronis*. A similar significance is perhaps to be attributed to the "intertentacular organ" of Farre—a ciliated passage opening between two tentacles of the lophophore in *Membranipora*, *Alcyonidium*, and other forms—through which Hincks has observed the spermatozoa to escape in large numbers. This organ occurs equally in female specimens of *Membranipora*, and is not therefore simply a spermatid duct.

Paludicella, as we have seen, develops both ova and spermatozoa in one and the same polypide. The details of impregnation and development have not been followed in this instance, but in some of the marine Eupolyzoa (*Gymnolæma*) remarkable bud-like structures termed *oeciæ* are developed for the special reception of the ova, and in these organs fertilization takes place. In the Entoprocta there is a peculiar brood-pouch. The spermatozoa of one polypide probably in all cases fertilize the ova of another, but we have not yet in many cases a knowledge of how the spermatozoa get to the eggs, or how the eggs escape from the body-cavity of the parent. In the hippocrepian freshwater Polyzoa (*Phylactolæma*) the ova appear to be fertilized and undergo the early stages of development within the body-cavity of the parent or in a hernia-like protrusion of it. Probably in such cases the embryos escape by the death of the parent and rupture of the parental tissues, as do also the peculiar asexual internal buds or statoblasts of these forms.

The embryo Polyzoon or "larva" swims freely in its early condition by means of cilia, and is in this condition a single polypide or "person." The forms assumed by these ciliated larvæ in different Polyzoa are very various and exceedingly difficult of interpretation. We shall have more to say with regard to them below (see Figs. 19, 20, 21). The ciliated larva then fixes itself and commences to produce polypides by a process of budding, the buds remaining not merely in contact but in organic continuity, and increasing continually in number so as to form a large colony or zoarium. In *Paludicella* we have seen that this colony has a simple tree-like form. The new buds form as wart-like growths, usually one, sometimes two in number, at the free end of a cell or zoecium near the spout-like process from which the tentacular crown is everted. In *Paludicella* all the polypides of a colony

are alike; there is no differentiation of form or distribution of function amongst the members of the colony. In many Eupolyzoa this simplicity is by no means maintained, but a great variety of form and function is assumed by various members of the aggregate. The only approach to a differentiation of the polypides in *Paludicella* is in the arrest of growth of some of the buds of a colony in autumn, which, instead of advancing to maturity, become conical and invested with a dark-colored cuticle. They are termed *hybernacula*. Should the rest of the polypides die down in winter, these arrested buds survive and go on to complete development on the return of spring.

In *Paludicella* we have thus seen a fairly simple and central example of Polyzoon structure and life-history. The variations upon this theme presented in different groups of Polyzoa have been to some small extent noted in the preceding account, but we shall now be able to indicate them more precisely by considering the various groups of Polyzoa in succession. The limit assigned to this article necessitates very large omissions. The reader who wishes to have the fullest information on the many difficult and uncertain matters connected with this subject is referred to Allman, *Freshwater Polyzoa* (Ray Society, 1856); Hincks, *British Marine Polyzoa* (Van Voorst, 1880); Haddon, "Budding in Polyzoa," *Quart. Journ. Micr. Sci.*, 1883; Balfour, *Embryology*, vol. i. p. 242; and the original memoirs cited by these writers.

THE VERMIFORMIA.

The first section of the Polyzoa comprises but a single genus, *Phoronis*. It differs from all other Polyzoa

FIG. 4.—*Phoronis hippocrepia*, Wright; magnified six times linear (from Allman). *a*, horse-shoe-shaped lophophore with tentacles; *c*, epistome (pra-oral lobe or prostomium); *d*, oesophagus; *f*, ventral vessel; *g, g*, two anterior vessels which unite to form *i*; *i*, longitudinal muscular coat of the body-wall; *k*, intertentacular membrane.

first in its greater size (species 2 inches long are known) and elaboration of organization, and correlatively with that in the fact that it does not produce buds. Further, it does not produce a closely adherent cuticular zoöcium as do *Paludicella* and the *Eupolyzoa* generally, but a leathery tube in which the animal freely moves, resembling that of some *Chætopods* (*Sabella*). Like some *Sabellæ*, *Phoronis* forms closely packed aggregates of individuals not brought together by any process of budding, but each separately developed from an egg. *Phoronis* has an elongate, wormlike, unsegmented body, with a conical posterior termination (like *Sipunculus*), and anteriorly provided with a horse-shoe-shaped crown of tentacles surrounding the mouth (Figs. 4, 5). There is an intertentacular "web" between the bases of the tentacles as in the *Phylactolæma*. Caldwell (6) has recently shown that the tentacles are supported by a mesoblastic skeleton, as is also the case in *Rhabdopleura*, but apparently not the case in any other *Polyzoa*. Close to the mouth, as in all *Polyzoa*, is placed the anus, outside the horse-

tem containing red-colored blood-corpuscles (Figs. 4, 5, *f, g, h*). A pair of ciliated canals acting as genital pores is found near the anus; these have been shown by Caldwell to be typical nephridia.

The development of *Phoronis* is remarkable. The

FIG. 5.—Lateral view of the anterior region of *Phoronis*. The tentacles of the right arm of the lophophore are cut short in order to expose clearly the mouth *b* and the overhanging "epistome" or pre-oral lobe *c*. *e*, intestine; *h*, dorsal vessel. Other letters as in Fig. 4.

shoe-shaped lophophore or tentacular platform (Fig. 11, *i*). The tentacular crown is not introvertible; in this point *Phoronis* differs from *Paludicella* and the Ectoproctous *Eupolyzoa*, and agrees with the Entoprocta and the Pterobranchia. Overhanging the mouth is a small pre-oral lobe or "epistome" (Figs. 4, 5, *c*). This organ is aborted in *Paludicella*, and indeed in all the *Gymnolæma*, but is present in the other *Polyzoa*, and is especially large and well developed in *Rhabdopleura* and *Cephalodiscus*. It has been compared to the Molluscan foot, but undoubtedly in *Phoronis* it is the persistent representative of the pre-oral lobe of the larva (Fig. 6), and therefore cannot be compared to the Molluscan foot. If we are right in associating *Phoronis* with the *Polyzoa*, this fact is sufficient to show that the epistome of the *Phylactolæma* (Fig. 11, *e*) and the buccal shield of *Rhabdopleura* (Fig. 7, *d*) and of *Cephalodiscus* (Fig. 9, *b*) are also cephalic in nature, and cannot rightly be identified with the post-oral and ventral muscular lobe known as the foot in Mollusca. A circum-oral nerve ring occurs at the base of the tentacles and sends off a cord which runs along the left side of the body. The alimentary canal presents the same general form and regions as in *Paludicella*. It hangs in the body-cavity, to the walls of which it is suspended by definite mesenteries.

Phoronis presents a closed contractile vascular sys-

FIG. 6.—Development of *Phoronis* and typical ciliate larvae. (1), (2), (3), (8), (9), (10), stages in the development of *Phoronis*—(1), earliest larva; (2), lateral view of the *Actinotrocha*; (3), ventral view of the same; (8), the ventral invagination *iv* is formed; (9), the ventral invagination is everted, carrying with it a loop of intestine; (10), the permanent relations of mouth, anus, and body (*Podaxonia*) are attained. (4), (5), Echinoderm larva with architroch, as in *Actinotrocha*, but band-like, not digitate. (6), Echinoderm larva, with the architroch divided into a pre-oral cephalotroch (Molluscan and Rotifer's velum), and a post-oral branchiotroch. (7), Chætopod trochosphere larva with cephalotroch only, and elongation and segmentation of the oro-anal axis. *a*, anus; *b*, mouth; *pr*, prostomium; *iv*, ventral invagination of *Phoronis* larva. *A B*, oro-anal axis; *V D*, dorso-ventral axis.

egg gives rise (after the usual phases of cleavage and gastrulation) to the larval form known as *Actinotrocha* (Fig. 6). This larva possesses a hood-like region overhanging the mouth and a number of ciliated post-oral processes or tentacles. The anus is placed at the extremity of the elongate body opposite to that bearing the mouth and pre-oral hood. The pre-oral hood becomes the epistome, and the tentacles, by further development (new tentacles replacing the larval ones), become the horse-shoe-shaped group of tentacles of the adult. A very curious process of growth changes the long axis of the body and results in the anus assuming its permanent position near the mouth. An invagination appears on the ventral face of the larva between the anus and mouth, and attains considerable size. At a definite moment in the course of growth this invagination is suddenly everted, carrying with it in its cavity the intestine in the form of a loop. Thus

a new long axis is suddenly established at right angles to the original oro-anal axis, and continues to develop as the main portion of the body. The short area extending from the præ-oral hood to the anus is thus the true *dorsal* surface of Phoronis, whilst the elongated body is an outgrowth of the ventral surface perpendicular to the primary oro-anal axis, as conversely in many Mollusca we find a short *ventral* area (the foot) between mouth and anus, and an outgrowth of the dorsal surface (the visceral hump) perpendicular to the primary oro-anal axis, forming the chief body of the animal. In these relations Phoronis (and with it the other Polyzoa) agrees with Sipunculus. On the other hand Echiurus, the Chaetopods, Nemertine worms, and some other groups which start from a simple larval form not unlike that of Phoronis, present a continual elongation of the original oro-anal axis, and no transference of the long axis by the perpendicular or angular growth of either the ventral or the dorsal surface of the larva.

Phoronis was discovered originally in the Firth of Forth by Dr. Strehill Wright. It occurs in the Mediterranean and in Australian seas (Port Jackson).

THE PTEROBRANCHIA.

This section of the Polyzoa also comprises forms which differ very widely from Paludicella. Inasmuch as their development from the egg is at present quite unknown, it may possibly prove that they have other affinities. Only two genera are known, Rhabdopleura (Allman) and Cephalodiscus (M'Intosh), the former dredged by Dr. Norman in deep water off the Shetlands (and subsequently in Norway), the latter taken by the "Challenger" expedition in 250 fathoms off the coast of Patagonia.

The Pterobranchia have the mouth and anus closely approximated, and immediately below the mouth are given off a series of ciliated tentacles, but these do not form a complete circle as in Paludicella, nor is the lophophore (the platform of their origin) horseshoe-shaped as in Phoronis. The lophophore is drawn out into a right and a left arm in Rhabdopleura (Fig. 7), upon each of which are two rows of ciliated tentacles; no tentacles are developed centrally in the region between the two arms, so that the mouth is not completely surrounded by these processes. The horse-shoe-shaped lophophore of Phoronis could be modified so as to represent the tentaculiferous arms of Rhabdopleura by suppressing both rows of tentacles at the curve of the horse-shoe, and leaving only those which occur on the arms or rami of the horse-shoe (see Fig. 4). The lophophore of Cephalodiscus presents us with twelve processes, each carrying two rows of ciliated tentacles; in fact we have six pairs of tentaculiferous arms instead of a single pair, and each of these arms is precisely similar to one of the arms of Rhabdopleura (Fig. 9), excepting that it terminates in a knob instead of tapering. There is no arrangement for introverting the anterior portion of the body into the hinder portion in the Pterobranchia.

The little epistome or præ-oral lobe of Phoronis is represented in the Pterobranchia by a large muscular shield or disk-like structure (Fig. 7, *d* and Fig. 9, *b*) which overhangs the mouth and has an actively secreting glandular surface by which the tube or case (tubarium) in which the polypide is enclosed is secreted.

Both Rhabdopleura and Cephalodiscus produce colonies by budding; but the colonies of the former are large, definite, and arborescent, whilst those of Cephalodiscus are remarkable for the fact that the buds do not remain long in organic continuity with their parent, but become detached and nevertheless continue to be enclosed by the same common envelope or secretion. The bud-formation of Rhabdopleura recalls that of Paludicella in the fact that it leads to the formation of continuous arboriform communities. That of Cephalodiscus resembles the budding of Lox-

osoma, since no two fully-formed individuals remain in organic continuity. Both Rhabdopleura and Cephalodiscus (like Phoronis) produce cases or invest-

FIG. 7.—*Rhabdopleura Normani*, Allman (original drawings, Lankester). A, A single polypide removed from its tube and greatly magnified. *a*, mouth; *b*, anus; *c*, polypide-stalk or gymnocaulus, the "contractile cord" of Sars; *d*, the præ-oral lobe (buccal shield or disk of Allman); *e*, intestine; *f*, thoracic region of the polypide; *g*, one of the ciliated tentacles. B, Lateral view to show the form of the buccal shield and its pigment spot. *g*, ciliated tentacle (in outline); *h*, basal ridge of the right arm of the lophophore. C, Lateral view of a polypide. *i*, ciliated patch (Sars's organ) at the base of the lophophore-arm. Other letters as above. D, Part of a lophophore-arm, with soft tissues rubbed off to show the cartilaginous skeleton. *a*, epithelium and soft tissues still adherent at the tip of a tentacle; *b*, skeleton of tentacle; *c*, skeleton of axis. E, Portion of a colony of *Rhabdopleura Normani*, showing the branched tube-like cases formed by the polypides. The black line within the tubes represents the retracted polypides connected together by their common stalk, the pectocaulus. Magnified to three times the size of nature.

ments in which they dwell. These are free secretions of the organism, and are not, like the cœnoecia of Eupolyzoa, cuticular structures adherent to and part of the polypide's integument. The dwelling of Rhabdopleura is a branched system of annulated tubes of a delicate membranous consistency, each tube corresponding to a single polypide, the rings of which it is built being successively produced at the termination of the tube by the secreting activity of the præ-oral disk (Fig. 7, B). The polypides freely ascend and descend in these tubes owing to the contractility of their stalks. On the other hand, the dwelling of Cephalodiscus is a gelatinous, irregularly branched, and fimbriated mass (Fig. 8), excavated by numerous cavities which communicate with the exterior. In these cavities are found the numerous detached small colonies of Cephalodiscus (Fig. 9), or we should rather say the isolated budding polypides. The remaining important feature in the organization of the Pterobranchia, namely, the parts connected with the formation of buds, are best understood by first exam-

ining *Cephalodiscus*. The body of *Cephalodiscus* is seen (Fig. 9) to be an oval sac; in this is suspended the U-shaped alimentary canal, and from the walls of its cavity (coelom) the ova and the spermatozoa are developed. Projecting from the ventral face of this oval sac is a muscular cylindrical stalk, into which the viscera do not pass, though the coelom is continued into it (Fig. 9, c). This stalk is merely the outdrawn termination of the body. It is about as long as the whole of the rest of the animal, and it is from its extremity that the buds are produced (Fig. 9, a). Before the buds have attained half the size of their parent they become detached, but continue to occupy some portion of the common gelatinous dwelling.

Turning to *Rhabdopleura*, we find that each polypide has a body of similar shape and character to that described for *Cephalodiscus*, and a similar ventrally developed "stalk" (Fig. 7, A, c). But, inasmuch as the buds developed on the stalk of a *Rhabdopleura* polypide do not detach themselves, we find that we

FIG. 8.—Dwelling of gelatinous consistence and brown color formed by the polypides of *Cephalodiscus dodecalophus*, M'Intosh; natural size (from an original drawing kindly supplied by Prof. M'Intosh, F.R.S.). a, polypide within the jelly; p, cavity once occupied by polypides.

FIG. 9.—A polypide of *Cephalodiscus dodecalophus* removed from the gelatinous house (from an original drawing by Prof. M'Intosh). No organic connection has been severed in thus isolating this polypide with its attached buds a, a. The figure represents the furthest point to which colony-formation attains in this form. a, buds growing from the base of the polypide stalk; b, the pre-oral lobe (buccal shield or disk); c, the polypide stalk; d, the ciliated tentacles of the twelve lophophore arms (six pairs, each like the single pair of *Rhabdopleura*) inextricably matted and confused; e, anterior margin of the pre-oral lobe; f, posterior margin of the same. Magnified about fifty times linear.

can trace the stalk of each polypide of a colony into connection with the stalk of the polypide from which it was originally budded, which may now be considered as a "branch" bearing many-stalked polypides upon its greatly extended length, and such a "branch-stalk" may be further traced to its junction with the "stem-stalk" of the whole colony. The stem-stalk was at one time the simple terminal stalk of a single polypide, but by lateral budding it gave rise to other polypides, and so became a gemmiferous "branch"; and further, when some of these in their turn budded and became branches, it became the main "stem" of a copious colony.

A serious error has been made in comparing the contractile stalk of the Pterobranchiate polypide to the

FIG. 10.—A Polypide of *Cephalodiscus dodecalophus*, from which the lophophore-tentacles and buccal shield have been removed in order to show the remarkable eyes. a, buds; c, stalk; g, eyes; h, post-oral collar, hidden by the buccal shield in Fig. 9. (Original drawing by Prof. M'Intosh, F.R.S.)

like mesentery of Eupolyzoa. With this it has morphologically nothing in common, since it is not an internal organ, but simply the elongated termination or stalk of the body, comparable to the stalk of *Pedicellina* (Fig. 15) and *Loxosoma* (Fig. 16), or to the hydrocaulus of such a Hydrozoan colony as *Cordylophora*. The stalk where it bears only very young buds, or none at all, as is always its condition in *Cephalodiscus* and in many polypides of a *Rhabdopleura* colony, may be called a "gymnocaulus"; when once its buds have developed into full grown polypides, and it has elongated proportionally with their growth, it becomes a "pectocaulus"; that is to say, it is to that part of it which bears such polypides that this term may be conveniently applied. The pectocaulus of *Rhabdopleura*, both in the form of branch and stem, undergoes remarkable change of appearance as compared with the gymnocaulus. It loses its contractility, shrinks, and develops on its surface a hard, dark, horny cuticle (whence its name), comparable precisely in its nature to the hardened cuticle which forms the zoecia of Eupolyzoa. It now has the appearance of a black cord or rod-like body lying within and adherent to the inner face of the much wider tubular stem, and branches formed by the gradual building up and arborescent extension of the annulated tubarium secreted by the individual polypides. It has been regarded both by Allman and by Sars as a special structure, and called by the former "the chitinous rod" or "blastophore," by the latter "the axial cord."

In reality it is the black-colored pectocaulus of *Rhabdopleura* which corresponds to the Coenœcium of an ordinary Polyzoon; whilst the term "coenœcium" is totally inapplicable morphologically to the annulated branched tube in which the *Rhabdopleura* colony lives, this having absolutely no parallel in the Eupolyzoa.

A sac-like testis has been discovered in *Rhabdopleura* opening by the side of the anus (Lankester, 7); but the ova have not yet been seen, nor is anything known of its development. Similarly the eggs of *Cephalodiscus* are observed within the body of the parent in the "Challenger" specimens, but nothing further is known of its life-history.

A body-cavity is present (Lankester), though its existence has been denied by Sars and M'Intosh.

Nephridia and nerve-ganglia are not described. Cephalodiscus has two remarkable eye spots dorsal to the cephalic disk (Fig. 10, *g*).

THE EUPOLYZOA.

Whilst it is necessary to include in the group Polyzoa the forms we have already noticed as Vermiformia and Pterobranchia, there can be no doubt that those organisms to which we assign the name Eupolyzoa are primarily those upon which naturalists have framed their conception of the group, and that they constitute a very consistent assemblage, held together by well-defined characters, and yet presenting an immense number of varied forms showing a wide range of modifications.

All the Eupolyzoa have closely approximated mouth and anus, and, like Paludicella, a complete range of hollow ciliate tentacles describing either a circle or a horse-shoe, surrounding the mouth. The anus as well as the mouth is included in this area in a few exceptional forms (the Entoprocta); it lies near but outside the lophophore (as the area is termed) in the vast majority (the Ectoprocta). Except in the Entoprocta, where the movement is limited, the whole anterior portion of the body bearing the lophophore can be invaginated into the hinder part (as described above for the typical Eupolyzoon Paludicella). This character distinguishes the Eupolyzoa from both Vermiformia and Pterobranchia. The polypides of all the Eupolyzoa are minute, but all produce buds which remain in organic continuity with their parent (except in Loxosoma) and build up very considerable and sometimes massive colonies.

In all Eupolyzoa the cuticle of the hinder part of each polypide is thick and dense, thus forming a hard-walled sac, the zoecium. This is peculiar to and universal in the Eupolyzoa (except Loxosoma), and is not to be confounded with the non-adherent tubes of Phoronis and Rhabdopleura or the jelly-house of Cephalodiscus. The connected zoecia of a colony of Eupolyzoa constitute a coenecium. A simple nerve-ganglion between mouth and anus, a large body-cavity (except in Entoprocta), simple gonads without accessory glands or ducts, usually testis and ovary in the same polypide, absence of a blood-vascular system, of any but the most rudimentary nephridia, and of eyes, otcysts, or other special sense-organs, are features characterizing all adult Eupolyzoa.

The section Eupolyzoa, with its vast number of species and genera, requires a somewhat elaborate classification. The forms in which the anus is enclosed within the tentacular circle are very few, and are peculiar in other respects. We follow Nitsche (8) in separating them as the sub-class Entoprocta from the majority of Eupolyzoa forming the sub-class Ectoprocta.

Sub-class 1. Ectoprocta, Nitsche.

Eupolyzoa with the anus not included within the area of the lophophore. Anterior portion of the body of the normal polypide introvertible. Tentacles not individually capable of being coiled or flexed.

Order 1. PHYLACTOLÆMA, Allman.

Ectoproctous Eupolyzoa in which the polypide possesses a præ-oral lobe or epistome, similar to that of Phoronis, and comparable to the more highly developed buccal shield or disk of the Pterobranchia. Lophophore (except in Fredericella, where it is nearly circular) horse-shoe-shaped (hippocrepian). Polypides of a colony equi-formal, that is, not differentiated in structure and function. Neighboring zoecia are in free and open communication, the bud never becoming shut off by a perforated cuticular plate from its parent. Cuticle of the zoecia either gelatinous or horny, forming massive or else arborescent coenecia, in one

genus (Cristatella) having the form of a plano-convex ellipse and locomotive (Fig. 3). In addition to the multiplication of polypides in a colony by budding, and to the annual production of new individuals from fertilized eggs which initiate new colonies, a reproduction by internal buds called "statoblasts," comparable to the gemmæ of Spongilla, has been observed in all the genera (Fig. 3, *b*). The statoblasts are developed from the funiculus (mesentery), and are enclosed in ornate lenticular capsules of chitinous substance, characteristic in form in each species.

The fertilized egg of the Phylactolæma does not give rise to a zoonchate larva, but to a uniformly ciliated cyst-like diblastula, which develops directly and

FIG. 11.—Semi-ideal view of part of the lophophore of *Lophopus amabilis*—intended to show the nerve-ganglion, nerves and parts around the mouth. The tentacles have been cut away all along the right arm of the lophophore and from the inner margin of the left arm. *c*, foramen placing the cavity of the epistome in communication with the body-cavity; *c*, body-wall; *d*, mouth; *e*, the epistome or præ-oral lobe; *f*, wall of the pharynx; *h*, wall of the intestine; *i*, anus; *k*, lophophore; *l*, a ciliated tentacle; *m*, elevator muscle of the epistome; *n*, the nerve-ganglion; *x*, *x'*, nerves to lophophore and tentacles; *y*, nerve to pharynx.

produces polypides by budding. The Phylactolæma are all inhabitants of fresh water (lacustrine).

The Phylactolæma include the genera *Lophopus*, *Cristatella*, *Alcyonella*, *Plumatella* and *Fredericella*, which have been beautifully figured and described in Allman's classical *Freshwater Polyzoa*, Ray Society, 1856. The colonies of *Lophopus* are small, consisting of half a dozen polypides embedded in a massive glass-like coenecium. *Cristatella* (Fig. 3) is remarkable amongst all Polyzoa for its locomotive zoarium. *Alcyonella* forms massive coenecia of many hundred polypides, as large as a man's fist. *Plumatella* and *Fredericella* are delicate arborescent forms commonly encrusting stones and the leaves of water-plants. All the genera known are British.

The Phylactolæma furnish a remarkable instance of a well-marked zoological group being confined to fresh water. Their reproduction by statoblasts (not known in the marine Polyzoa) appears to be related to the special conditions of lacustrine life, since it is also observed under the same exceptional conditions in the single freshwater genus of another great group of animals, viz, *Spongilla*. Also related to their non-marine conditions of life is the development of the fertilized egg, which, as in so many similar cases, does not produce the remarkable banded forms of locomotive larvæ which are characteristic of their marine congeners.

Order 2. GYMNOLEMA, Allman.

Ectoproctous Eupolyzoa in which the polypide is devoid of any trace of the præ-oral lobe or epistome, whilst the lophophore is perfectly circular. The polypides of a colony are frequently highly differentiated as avicularia, vibracularia, oœcia (egg-receptacles), and even as root and stem segments. The neighboring polypides of a colony communicate (?) with one another by "rosette-plates" or "communication-plates"—perforated areas in the walls of contiguous zoœcia. The greatest variety in the character of the cuticle forming the zoœcia (gelatinous, horny, calcareous) and in the grouping of the polypides, as well as in the shape of their zoœcia, is observed in different sub-orders and families. In addition to the ordinary sexual reproduction, there are various modifications of the process of budding, the full exposition of which would necessitate more space than is here allotted, and is not yet indeed within the possibilities of present knowledge. The fertilized egg of the Gymnolœma gives rise to remarkable ciliate larvæ of various forms (Figs. 19, 20, 21), from which the first polypide of a colony is developed by an extraordinary and unexplained series of changes. The Gymnolœma are, with the single exception of the genus *Paludicella*, inhabitants of the sea.

The Gymnolœma are divided, according to the system of Busk, into three sub-orders characterized by the shape of their zoœcia, and the nature of the mouth-like margin which it presents when the exsertile portion of the polypide is withdrawn within it. The *Cyclostoma* have long tubular zoœcia, often of large size and often calcified, placed side by side in cylindrical bundles, or in other definite grouping; the mouth of the zoœcium is circular and devoid of processes. There is little or no differentiation of the polypides constituting a colony. Most of this group are fossil, and the living genera belong mostly to southern seas. The genera *Crisia* (Fig. 13, A), *Diastopora*, *Tubulipora*, and *Hornera* are typical. The *Ctenostoma* have usually a soft zoœcium; its orifice is closed by the folds of the retracted polypide or by a circle of bristles which surround it. *Alecyonidium gelatinosum* is the commonest representative of this group on the British coasts. *Bowerbankia* (Fig. 1, A) and *Paludicella* (Fig. 1, E) also belong here. The *Chilostoma* form the largest and most varied suborder of Gymnolœma. The zoœcia are horny or calcified; their orifices can be closed by a projecting lip in the form of an operculum. The operculum is a separable plate developed on the cuticle of the retractile part of the polypide, and has muscles attached to it (Fig. 13, B, C, D). The surface of the zoœcia is frequently sculptured, and its orifice provided with processes and spines (Fig. 1, C, F). Very usually some of the polypides of a colony are modified as avicularia, vibracularia, radical fibres and oœcia. The avicularium is a polypide reduced to a simple muscular apparatus working upon the modified operculum and zoœcium so as to cause these hard parts to act as a snapping apparatus comparable to a bird's head (Fig. 12, o). They are frequently found regularly

FIG. 12.—Two zoœcia of *Acamarchis* (*Bugula*) *avicularia*, Lmx. (*Chilostoma*), of which the anterior contains a living polypide, whilst the posterior is empty. To each is attached one of the characteristically modified polypides known as an "avicularium" o; the hinder of these has grasped and holds in its beak a small worm. a, anus; i, intestine; s, stomach; r, body-cavity (coelom); t, tentacular crown surrounding the mouth; te, testis cells developed on the surface of the terminal mesentery or "funiculus"; o, o, avicularia.

distributed among the normal cells of a colony, and probably have a cleansing function similar to that attributed to the Pedicellariæ of the Echinoderms. "Vibracularia" are even more simplified polypides, being little more than motile filaments, probably tactile in function. The opercula of zoœcia, oœcia, and avicularia have recently been used by Busk in characterizing genera and species, in a systematic way. Stem-building and root-forming polypides are frequently found, being closed polypides which subserve anchoring or supporting functions for the benefit of the whole colony. The stem of *Kinetoskias* (Fig. 14) is produced in this way. The *Chilostoma* include a large series of genera arranged in the sections *Cellularina*, *Flustrina*, *Escharina*,

FIG. 13.—A. Canœcium of *Crisia eburnea*, Lin., one of the *Cyclostoma*; g, g, tubular zoœcia with circular terminal mouths; z, oœcium, being a zoœcium modified to serve as a brood-chamber.

B. C. The same zoœcium with the polypide invaginated (telescoped) and the operculum a shut down over the mouth of the zoœcium.

D. Operculum detached, and seen from its inner face, to show the occlusor muscles d d.

and *Celleporina*. For the systematic description of the highly complex and very varied colonial skeletons or canœcia of the Gymnolœma, the reader is referred to the works of Busk (9), Hicks (10), Smitt (11), and Heller (12). See also Ehlers (13) on *Hypophorella*.

Sub-class 2. Entoprocta, Nitsche.

Eupolyzoa in which the anal aperture lies close to the mouth within the tentacular area or lophophore. Lophophore sunk within a shallow basin formed by the inversion of the broad truncated extremity of the cup-shaped body. Tentacular crown not further introvertible, the individual tentacles (as in the *Pterobranchia* and unlike the *Ectoprocta*) capable of being flexed and partially rolled up so as to overhang the mouth (see Fig. 15, B and C). Body-cavity (coelom) almost completely obliterated. The anti-tentacular region of the polypide's body is drawn out to form a stalk similar to the *gymnocaulus* of the *Pterobranchia*. The extremity of this stalk is provided with a cement gland in the young condition which persists in the adult of some species (*Loxosoma neapolitanum*, Fig. 16, shs). Cuticular investment (zoœcium) of the polypides feebly developed. A pair of small nephridia are present.

The Entoprocta consist of the marine genera *Pedicellina* (Fig. 15), *Loxosoma* (Fig. 16), and probably the insufficiently known freshwater American genus *Urnatella* of Leidy. To these must be added Busk's new genus *Ascopodaria*, as yet undescribed, based on a specimen dredged by the "Challenger," showing a number of *Pedicellina*-like polypides, carried as an umbel on a common stalk of very peculiar structure. *Pedicellina* is found attached to algæ, shells, zoophytes, etc., and to the integument of some Gephyræan worms (*Sipunculus punctatus*) and Annelids (*Aphro-*

dite); *Loxosoma* occurs on various worms, etc. Whilst the buds of *Pedicellina* remain connected so as to con-

Loxosoma at the present day, but of relatively large size and more elaborately organized than the majority

FIG. 14.—*Kinetoskias (Naresia) cyathus* (from Sir Wyville Thomson). The polypides and zoecia are allied to *Bugula*, but the zoarium as a whole is remarkable for its definite shape, consisting of a number of slightly branched gracefully bending filaments supported like the leaves of a palm on a long transparent stalk. (See Busk, in *Quart. Journ. Micr. Sci.*, 1881, for further details.)

stitute a colony, those produced by *Loxosoma* are continually detached, so that the polypide is solitary. Further, the cup-like body of *Pedicellina* is deciduous, and frequently falls from the stalk and is replaced by new growth. There is less distinction between body and stalk in *Loxosoma*, and the former does not become detached. Apparently a very important feature in the structure of the Entoprocta is the absence of a body-cavity. This is, however, more apparent than real. The Entoprocta are true Coelomata, but the coelom is partially obliterated by the growth of mesoblastic tissue. The nephridia presumably lie in a space which, small as it is, represents the coelom. See Harmer (18) for details.

Genealogical Relationships of the Groups of Polyzoa.

It is necessary that we should try to form some opinion as to which of the various groups of Polyzoa are most like the ancestral form from which they have all sprung, and what are the probable lines of descent within the group. Any attempt of the kind is speculative, but it is absolutely needful since zoology has become a science—that is to say, an investigation of causes and not merely a record of unexplained observations—to enter upon such questions. Colonial organisms have necessarily descended from solitary ancestors, and it is probable that the ancestral form of Polyzoa was not only solitary, as are *Phoronis* and

FIG. 15.—A. Two polypides and buds of *Pedicellina belgica*, Van B. (after Van Beneden); greatly magnified. *a*, the polypide-stalk of a fully developed polypide; *c*, that of a less mature individual; *b*, a bud. All are connected by a common stalk or stolon. B. and C. Two views of the body of the polypide of *Pedicellina* (after Allman). *a*, cuticle; *b*, body-wall; *c*, permanently introverted anterior region of the body; *d*, margin of the tentacular cup or calyx thus formed; *e*, mouth; *f*, pharynx; *g*, stomach; *h*, intestine; *i*, anus; *k*, epistome or pre-oral lobe; *l*, nerve-ganglion; *m*, gonad; *n*, retractor muscle of the lophophore; *o*, lophophore.

of living Polyzoa. Whilst the polypides have dwindled in size and lost some of their internal organs, the modern Polyzoa have developed *pari passu* with this

FIG. 16.—Diagram of *Loxosoma Neapolitanum* (after Kowalewsky). A single polypide devoid of buds. *m*, mouth; *st*, stomach; *shs*, basal gland of the polypide-stalk.

degeneration an elaborate system of bud-production and colony-formation. The new individuality (the tertiary aggregate) attains a high degree of development (Cristatella, Kinetoskias) in proportion as the constituent units merged in this new individuality have suffered a degeneration. The præ-oral lobe (epistome, buccal disk) present in all Polyzoa except the most minute and most elaborately colonial forms—namely, the Gymnolæma—is to be regarded as an ancestral structure which has been lost by the Gymnolæma. The horse-shoe-shaped lophophore, such as we see it in Phoronis and in Lophopus, is probably the ancestral form, and has given rise to the two other extreme forms of lophophore,—namely, the “pterobranchiate,” associated with a great development of the epistome, and the “circular,” associated with a complete suppression of the epistome. The entoproctous lophophore is a special modification of the horse-shoe-shaped, as shown in the diagram Fig. 15, C. The formation of zoecia, and so of an elaborate colonial skeleton, was not a primary feature of the Polyzoa. Even after budding and colony-formation had been established zoecia were not at once produced, but possibly dwellings of another kind (Pterobranchia). We are thus led to look upon the Gymnolæma as the extreme modification of the Polyzoan type. Starting with an organism similar to Phoronis, we may suppose the following branchings in the pedigree to have occurred.

VERMIFORMIA

A. The complete hippocrepian lophophore becomes specialized in the form of ctenidia or gill-plumes; the epistome enlarged.

— PTEROBRANCHIA.

a. The anti-tentacular region of the body elongated as a stalk gives rise to one or two rapidly detached buds (Cephalodiscus).

β. The stalk gives rise to buds which do not detach themselves, but remain in continuity so as to form a colony of a hundred or more individuals (Rhabdopleura).

A. The anti-tentacular region of the body becomes stalk-like, and develops buds which either detach themselves as they form (Loxosoma) or remain to form a small colony (Pedicellina). The telescopic introversibility of the lophophore does not advance beyond the initial stage. The arms of the lophophore grow round so as to embrace the anus.

— Sub-class 1 (of the Eupolyzoa) Entoprocta.

B. The complete hippocrepian lophophore retains its form, but acquires a gradually increasing power of being telescoped into the hinder part of the body.

— The Pro-Eupolyzoan.

B. The complete hippocrepian lophophore remains in its original form, and also the præ-oral epistome, but the telescopic introversibility of the anterior region of the body is greatly developed at the same time that the cuticle of the hinder part of the body is increased in thickness and toughness. Bud production, not from a stalk-like pedicle, but from all parts of the body, now becomes characteristic, the buds, which were at first deciduous, now remaining in permanent continuity so as to form colonies.

— The Pro-Ectoprocton.

A. The polypides acquire the property of carrying their young so as to avoid the disastrous influences of fluvial currents, and also the property of producing resistant statoblasts, and thus are enabled to become isolated and to persist in the peculiar conditions of fresh waters.

— The 1st order (of Ectoprocta) Phylactolæma.

B. The polypides forming relatively larger colonies, and themselves becoming relatively more minute, lose by atrophy the præ-oral epistome; and simultaneously the arms of the hippocrepian lophophore dwindle, and a simple circum-oral circle of tentacles is the result. The cuticle of the hinder part of the polypide becomes more and more specialized as the cell or zoecium, and in different polypides in various parts of the colony acquires special forms—as egg-cases, snappers (avicularia), tentacles, stalk and root segments.

— The 2d order (of Ectoprocta) Gymnolæma.

Distinctive Characters of the Polyzoa.

From all that has preceded it appears that the really distinctive characters common to all the Polyzoa may be summed up as follows:

Celomata with closely approximated mouth and anus, the bulk of the body forming a more or less elongate growth at right angles to the original (ancestral) oro-anal axis, and starting from the original ventral (i.e., oral) surface. A variously modified group of ciliated tentacles is disposed around the mouth, being essentially the development by digitiform up-growth of a post-oral ciliated band. As negative characters it is important to note the absence of all trace of metameric segmentation, of setæ, and of paired lateral (parapodia of Appendiculata) or median ventral (podium of Mollusca) outgrowths of the body-wall.

Larval-Forms of Polyzoa.

In the consideration of the probable pedigree and affinities of the Polyzoa, we are not at present able to make use of the facts of development from the egg, on account of the extreme difficulty which the study of the young stages of these organisms presents. In the case of Phoronis we have the only readily intelligible history. The larva, to start with, is of that form known as an architroch

FIG. 17.

FIG. 18.

FIG. 17.—Larva of Pedicellina (from Balfour, after Hatschek) v, vestibule (the cup-like depression of the tentaculiferous end of the body); m, mouth; l, digestive gland; an.i, anal invagination; fg, the ciliated disk (corresponding to the cement gland of Loxosoma (Fig. 16, shs); x, so-called “dorsal organ,” supposed by Balfour to be a bud, by Harmer (18) regarded as the cephalic ganglion.

FIG. 18.—Later stage of the same larva as Fig. 17. Letters as before, with the addition of nph, duct of the right nephridium; a, anus; hg, hind-gut.

(see Lankester, “Notes on Embryology and Classification,” Quart. Journ. Micr. Sci., 1876), having a præ-oral ciliated area (velum or cephalotroch) continuous with a post-oral ciliated band (the branchiotroch), which latter becomes developed into the tentacular crown of the adult.

The actinotrocha (Phoronis) larva is readily comparable with the trochosphere larvæ of Echinoderms, Chaetopods, Gephyreans, and Molluscs. Its special character consists in the strong development of the post-oral ciliated band, whereas the præ-oral ciliated band is in most other classes (the Sipunculoids excepted) the predominant one. The Phoronis larva exhibits first of all an oro-anal long axis, and this is suddenly abandoned for a new long axis, by the growth of the ventral surface of the larva at right angles to the primary axis (hence the term Podaxonina).

In the other Polyzoa we do not at present know of any larva which retains even in its earliest phases the original oro-anal long axis. They all appear to start at once with the peculiar and secondary long axis of the adult Phoronis, so that Balfour has diagrammatically represented the Polyzoan larva by the sketch given in Fig. 19. This diagram applies, however, more especially to the Entoprocta, since the anus is represented as included in the area of the post-oral ciliated ring. The development of Pedicellina has been very carefully followed by Hatschek, and may be said to be the only instance among the Eupolyzoa,

In which the growth of the different organs and the consequent relation of the form of the larva to the form of the adult is understood (see Figs. 17 and 18).

In the other Polyzoa, in spite of the painstaking and minute studies of Barrois (14), the fact is that we do not know what face of the larva corresponds to the tentacular area, what to the stalk or anti-tentacular extremity, what to the anterior and what to the posterior surface. The conversion of the larva into the first polypide has not been observed in the case of these free-swimming forms, and it is even probable that no such conversion ever takes place, but that the first polypide forms as a bud upon the body-wall of the larva.

Two of the most remarkable forms of free-swimming larvae of *Gymnolæma* are represented in Figs. 20 and 21. In both, in addition to the chief post-oral ciliated band, a smaller ciliated ring is observed, which is identified by Balfour with that which is found at the anti-tentacular extremity (base of the stalk) in the *Pedicellina* larva.

It does not seem justifiable, in the face of the existing uncertainties as to the identification of parts, and in view of

FIG. 20.—Larva of *Alcyonidium mytili* (from Balfour after Barrois). *m?*, problematic structure; *st*, oral invagination (*p*)=Harmer's cephalic ganglion; *s*, ciliated disk (corresponding to *fg* in Figs. 17, 18, and 21).

the high probability that the *Gymnolæma* are extremely modified and degenerate forms (a consideration which applies in some respects even more strongly to the *Entoprocta*), to assume that the larval form schematized in Fig. 19 represents an ancestral condition of the Polyzoa. Professor Balfour (15) was, however, led to entertain such a view, and, assuming that the chief ciliated band (drawn

FIG. 21.—Larva of *Membranipora* (known as *Cyphonantes*). *m*, mouth; *a*, anus; *fg*, ciliated body; *x*, problematical body, supposed by Balfour to be a bud, similar to the dorsal organ *x* in Figs. 17, 18, and to either *st* or *m* in Fig. 20.

as a broad black line) corresponds to the single pre-oral ciliated band of the trochosphere larva of *Echiurus*, *Polygordius*, *Chætopods*, and *Mollusca*, he pointed out that in both cases the ciliated girdle divides the larva into a hemisphere in which mouth and anus lie and a hemisphere which is the complement of this; in most classes the first hemisphere elongates and forms the bulk of the body, whilst the second hemisphere forms the prostomium or pre-oral lobe. But, according to Balfour's theory, in *Polyzoa* it is the second hemisphere which enlarges and becomes

the stalk-like body of the adult,

FIG. 22.—Young *Terebratulina* at a stage when only six tentacles are present. *se*, setæ at the margin of the calyx; *p*, stalk comparable to the stalk of *Pedicellina*, *Loxosoma*, *Cephalodiscus*, and *Rhabdopleura*; *pa*, cement gland at the apex of the stalk (after Morse).

groups. Lastly, Caldwell (6) has shown that the mesenteries of *Phoronis* have precisely similar relations to the lophophore, the nephridia, and the termination of the intestine as have the gastro-parietal and ilio-parietal bands or mesenteries of the *Terebratulidæ*. The young *Terebratulina* (Fig. 22) may be readily compared with *Loxosoma* (Fig. 16),—the peduncle with its cement glands in the former being identical with the stalk and basal gland of the latter. The form of the alimentary canal and the disposi-

whilst the first hemisphere remains small and insignificant. Thus the Polyzoa would fix themselves in later growth by what corresponds to the head or prostomium of other animals, as do the *Barnacles* and the *Ascidians*. Ingenious as this speculation is, we must remember that it takes no account of the facts known as to *Phoronis*, nor of the *Pterobranchia*, and that it is confessedly based upon the assumption that the larva of extremely degenerate and peculiar members of the group are not adaptive and modified, but retain primary and archaic characters. Further, it is to be distinctly borne in mind that the interpretation of parts upon which this speculation rests is, except in the case of *Pedicellina*, altogether hypothetical.

Relations of the Polyzoa to the Brachiopoda.

The Polyzoa were first associated with the Brachiopoda by H. Milne-Edwards. The investigation of the development of *Terebratulina* by Morse (16) led to a further perception of the points of agreement in structure between these two

FIG. 23.

FIG. 23.—Lophophore and epistome of young *Terebratulina*, showing the horse-shoe shape; the arms are turned in the direction the reverse of that taken by the lophophore-arms in *Polyzoa* (see Fig. 4). In later growth they will become spirally coiled. (After Morse).

FIG. 24.—Larva of the Brachiopod *Argiope* (from Gegenbaur, after Kowalewsky). *m*, setigerous lobe; *b*, setæ; *d*, enteron.

tion of the tentacular arms (Fig. 23) is the same in Brachiopoda and Polyzoa. The nephridia (oviducts) of *Terebra-*

tula have a position and relations similar to those of the nephridia (genital ducts) of Phoronis. The chief difference between Polyzoa and Brachiopoda consists in the special development of the margin of the cupped end of the body, into which the lophophore is sunk, as in *Pedicellina* (see Fig.

FIG. 25.—Surface views of ten stages in the development of *Terebratulina*, showing the free-swimming larva and its mode of fixation (after Morse). c, lophophoral segment; th, thoracic segment; p, peduncular segment; ds, deciduous setae.

15, B, c). This up-standing margin is enormously increased in the Brachiopoda, so as to form a voluminous hood or collar, which surrounds the large tentacular arms, and forms a protective chamber for them. It is notched right and left so as to be divided into two lobes, and on its surface is developed a horny or a calcareous shell in two corresponding moieties. Until recently it was held (see Lankester, 17), that both Brachiopoda and Polyzoa were modifications of the Molluscan type, and the Brachiopods' collar was identified with the pallial fold of Mollusca. The resem-

blance of the two structures must now be considered as purely homoplastic, and not as having any real morphological (homogenetic) significance.

The larvæ of the Brachiopoda (Figs. 24, 25) are as exceptional and difficult of interpretation as those of Polyzoa, but no attempt has been yet made to show that the one can be reduced to a common form with the other. The three segments presented by some Brachiopod larvæ (Fig. 25) have been compared to the segments of Chaetopod worms by some writers, and these, together with the presence of setæ, have been regarded as indicative of affinity between the Brachiopoda and Chaetopoda (Morse). But it is sufficient, in order to dispose of this suggestion, to point out that the segments of the Chaetopoda follow one another along the primary oro-anal axis, whilst those of Brachiopoda are developed along an axis at right angles to this (Caldwell).

The Brachiopoda must be classified together with the Polyzoa and Sipunculoidea in a phylum (Podaxonia) characterized by the development of this secondary axis.

POMBAL, SEBASTIAN JOSEPH DE CARVALHO E MELLO, MARQUIS DE (1699-1782), the greatest statesman Portugal has produced in modern times, was the son of a fairly wealthy country gentleman, Emmanuel de Carvalho, and was born at Soure, near Pombal, on 13th May, 1699. He was educated at the university of Coimbra, and was then for a short time in the army, but it was not until he was nearly forty and had been married some years that he received his first public appointment, and was sent as minister to London in 1739. There he studied English administration, but never learnt the English language, and was promoted to the embassy at Vienna by King John V. in 1745, and recalled in 1750 to become minister for foreign affairs. Before he reached Lisbon John was dead, and his successor, King Joseph, at once placed entire confidence in him. He soon began to show his strength. In 1751 he checked the Inquisition by allowing no executions without the royal permission, he improved the navy, the police, and the finances, and freed the Indians of the Brazils from slavery. The great earthquake of Lisbon on 1st November, 1755, showed him in his true greatness; when the king asked him despairingly what he should do, he answered briefly: "Bury the dead and feed the living," and by his calmness at that frightful moment gained an ascendancy over the royal mind which lasted till Joseph's death. His power was at once used to check the Roman Catholic Church, which, with the Jesuits and the Inquisition, had eaten the life out of the country, and in 1757 the Jesuits were expelled from court (see *JESUITS*, vol. xiii. p. 665). The Count d'Oeyras, as he was now made, then devoted himself to internal administration; he founded the Oporto Wine Company, encouraged sericulture, rebuilt Lisbon, and improved on the Jesuit system of education, and in 1762, showed his concurrence in the hereditary policy of Portugal in helping England against Spain, when the Family Compact had united the interests of Spain and France. On the 3d September, 1769, an attempt on the king's life was frustrated by the count, who was in

1770 made marquis of Pombal. He remained in power till the death of the king in 1777, but the new sovereign, Queen Maria, at once accepted his resignation, and persecuted him till his death in 1782.

POMEGRANATE. The pomegranate (*Punica Granatum*) is of exceptional interest by reason of its structure, its history, and its utility. It forms a tree of small stature, or a bush with opposite, shining, lance-shaped leaves, from the axils of some of which proceed the brilliant scarlet flowers. These are raised on a short stalk and consist of a thick fleshy cylindrical or bell-shaped calyx tube, with five to seven short lobes at the top. From the throat of the calyx proceed five to seven roundish, crumpled, scarlet or crimson petals, and below them very numerous slender stamens. The pistil consists of two rows of carpels placed one above another, both rows imbedded in, and partially inseparate from, the inner surface of the calyx tube. The styles are confluent into one filiform thread. The fruit, which usually attains the size of a large orange, consists of a hard, leathery rind, which is the enlarged calyx tube, enclosing a quantity of pulp derived from the coats of the numerous seeds. This pulp, filled as it is with refreshing acid juice, constitutes the chief value of the tree. The more highly cultivated forms

FIG. 1.

FIG. 2.

Transverse sections of the lower and upper parts of the berried fruit of the Pomegranate.

and in the fact that, while in the lower series (Fig. 1) the seeds are attached to the inner border or lower angle of the cavity, they occupy the outer side in the

contain more of it than the wild or half-wild varieties. The great structural peculiarity consists in the presence of the two rows of carpels one above another (a state of things which occurs exceptionally in apples and oranges),

upper series (Fig. 2), as if, during growth, the upper whorl had become completely bent over.

By Benthham and Hooker the genus *Punica* is included under *Lythraceæ*; others consider it more nearly allied to the myrtles; while its peculiarities are so great as, in the opinion of many botanists, to justify its inclusion in a separate order. Not only is the fruit valuable in hot countries for the sake of its pulp, but the rind and the bark and the outer part of the root are valuable as astringents owing to the large quantity of tannin that they contain. The bark of the root is likewise valued in cases of tape-worm.

The tree is without doubt wild in Afghanistan, north-western India, and the districts south and southwest of the Caspian, but it has been so long cultivated that it is difficult to say whether it is really native in Palestine and the Mediterranean region. It has been cited as wild in northern Africa, but this appears to be a mistake. Recently, however, Prof. Bayley Balfour met with a wild species, heretofore unknown, in the island of Socotra, the flowers of which have only a single row of carpels, which suggests the inference that it may have been the source of the cultivated varieties. But, on the other hand, in Afghanistan, where Aitchison met with the tree truly wild, a double row of carpels was present as usual. The antiquity of the tree as a cultivated plant is evidenced by the Sanskrit name *Dadimba*, and by the references to the fruit in the Old Testament, and in the *Odyssey*, where it is spoken of as cultivated in the gardens of the kings of Phœacia and Phrygia. The fruit is frequently represented on ancient Assyrian and Egyptian sculptures, and had a religious significance in connection with several Oriental cults, especially the Phrygian cult of Cybele (Arnob., v. 5 sq.; see also Baudissin, *Studien*, ii. 207 sq.). It was well known to the Greeks and Romans, who were acquainted with its medicinal properties and its use as a tanning material. The name given by the Romans, *malum punicum*, indicates that they received it from Carthage, as indeed is expressly stated by Pliny; and this circumstance has given rise to the notion that the tree was indigenous in northern Africa. On a review of the whole evidence, botanical, literary, and linguistic, Alphonse de Candolle (*Origine des Plantes Cultivées*) pronounces against its African origin, and decides in favor of its source in Persia and the neighboring countries. According to Saporta the pomegranate existed in a fossil state in beds of the Pliocene epoch near Meximieux in Burgundy. The pomegranate is sometimes met with in cultivation against a wall in England, but it is too tender to withstand a severe winter. The double-flowered varieties are especially desirable for the beauty and long duration of their flowers.

POMERANIA (Germ. *Pommern*) is a maritime province of Prussia, bounded on the N. by the Baltic, on the W. by Mecklenburg, on the S. by Brandenburg, and on the E. by West Prussia. Its area is 11,620 square miles. The province is officially divided into the three districts of Stralsund, Stettin, and Cöslin; but more historical interest attaches to the names of Vorpommern and Hinterpommern, or Hither and Farther Pomerania, applied to the territory to the west and to the east of the Oder respectively. As a whole Pomerania is one of the lowest and flattest parts of Germany, but to the east of the Oder it is traversed by a range of low hills, and there are also a few isolated eminences to the west. Off the west coast, which is very irregular, lie the islands of Rügen, Usedom, and Wollin; the coast of Farther Pomerania is smooth in outline and bordered with dunes or sandbanks. Besides the Oder and its affluents, there are several small rivers flowing into the Baltic, none of which, however, are navigable except for rafts. Many of these end in small littoral lakes, separated from the sea by a narrow strip of land through which the water escapes by one or more outlets. The interior of the province is also thickly sprinkled with lakes, the combined area of which is equal to about one-twentieth of its entire surface. The soil of Pomerania is for the most part thin and sandy, especially to the east of the Oder; but patches of good soil occur here and there. About 55 per cent. of the surface is under tillage, while 19 per cent. consists of meadow and pasture and 20 per cent. is covered by forests. The principal crops are potatoes,

rye, and oats, but wheat and barley are grown in the more fertile districts; tobacco and beetroot for sugar are also cultivated. Agriculture is still in many respects carried on in a somewhat primitive fashion, and the live stock is as a rule of an inferior quality. Large flocks of sheep are kept both for their flesh and wool, and geese and goose-feathers form lucrative articles of export. (A tabular view of the agricultural products of Pomerania will be found under PRUSSIA.) Owing to the long coast-line and the numerous lakes, fishing forms a not unimportant industry, and large quantities of herring, eels, lampreys, etc., are sent from Pomerania to other parts of Germany. With the exceptions of its inexhaustible layers of peat or soft coal, the mineral wealth of Pomerania is insignificant. Its industrial activity is also of no great importance, though there are a few manufactories of machinery, chemicals, tobacco, sugar, and other articles, chiefly in or near the larger towns, and linen-weaving is practiced as a domestic industry. Ship-building is carried on at Stettin and other places on the coast. Commerce, however, is relatively much more flourishing. Stettin is one of the chief seaports of Prussia, and Stralsund, Greifswald, and Colberg also possess a foreign trade, the exports consisting mainly of grain, timber, and fish.

In 1880 Pomerania contained 1,540,034 inhabitants, all of whom were Protestants except 23,877 Roman Catholics and 13,886 Jews. The Slavonic element in the population is now represented only by a few thousand Poles and a handful of the ancient Cassubians on the east border. Pomerania is the most sparsely populated province in Prussia, the ratio being 132 inhabitants per square mile. About 67 per cent. of the population belong to the rural districts, while the remainder live in communities of 2000 and upwards. There are only nine towns with more than 10,000 inhabitants, at the head of which stands Stettin with 91,000. The Pomeranians belong mainly to the old Saxon stock, and are, as a rule, tall, strong, and well-built. They somewhat resemble the Scots in their cautious and persevering character, their strong theological bias (which perpetuates the existence of numerous small Protestant sects), and their turn for dry humor; but they are by no means so enterprising or so open to new ideas. In 1883 only 0.32 per cent. of the Pomeranian recruits were illiterate, a fact which speaks well for the educational system of the province. There is a university at Greifswald. The province sends 16 members to the reichstag and 26 to the Prussian house of representatives. The heir-presumptive of the Prussian crown bears the title of governor of Pomerania.

History.—In prehistoric times the southern coast of the Baltic seems to have been occupied by Celts, who afterwards made way for tribes of Teutonic stock. These in their turn migrated to other settlements and were replaced, about the beginning of the 6th century of our era, by Slavonians. The name of Pomore or Pommern, meaning "on the sea," was attached to the district by the last of these immigrant races, and has often changed its political and geographical significance. Originally it seems to have denoted the coast district between the Oder and the Vistula, a territory which was at first more or less dependent on Poland, but which appears towards the end of the 12th century as divided between two native dukes owning the supremacy of the German emperor. Afterwards Pomerania spread much farther to the west, while correspondingly curtailed on the east, and a distinction was made between Slavonia, or modern Pomerania, and Pomerellen. The latter, corresponding substantially to the present province of West Prussia, remained subject to Poland down to the beginning of the 14th century, when part of it fell away to the Teutonic knights and part of it was annexed to the duchy of Pomerania-Wolgast. Christianity was introduced in the 12th century, and its advance went hand in hand with the Germanizing of the district. The later mediæval history of Pomerania is occupied with an endless succession of subdivisions among different lines of the ducal houses, and with numerous expansions and contractions of territory through constant hostilities with the elector of Brandenburg, who claimed to be the immediate feudal superior of Pomerania, and with other neighboring powers. The names Vorpommern and Hinterpommern were at first synonymous with Slavonia and Pomerellen, but towards the close of the 14th century they were transferred to the two duchies into which the former (Pomerania proper) was divided. In 1625 the whole of Pomerania became united under the sway of Bogeslaus XIV., and, on his death without issue in 1637,

Brandenburg laid claim to the duchy in virtue of a compact of 1571. The Swedes, however, had in the meantime occupied the country, and at the peace of Westphalia (1648) the elector had to content himself with East Pomerania and see the other half awarded to Sweden. In 1720 Swedish Pomerania was curtailed by extensive concessions to Prussia, but the district to the west of the Peene remained in possession of Sweden down to the dissolution of the German empire. On the downfall of Napoleon, Sweden assigned her German possessions to Denmark in exchange for Norway, whereupon Prussia, partly by purchase and partly by the cession of Lauenburg, finally succeeded in uniting the whole of Pomerania under her sway.

POMEROY, a city of the United States, in Meigs county, Ohio, lies on the right bank of the Ohio about half-way between Pittsburgh and Cincinnati. It is the terminus of the Ohio River division of the Columbus, Hocking Valley, and Toledo Railway, and has extensive coal mines dating from 1833, salt works (14,000,000 bushels per annum), and bromine factories. Incorporated as a village in 1841 and as a city in 1868, Pomeroy had 5824 inhabitants in 1870 and 5560 in 1880.

POMFRET, JOHN (1667-1703), holds a certain place in English letters as the author of a short poem, *The Choice*, which embodies in easy and happy Drydenic diction the refined Epicureanism of the 18th century, and was consequently widely popular throughout that century. Pomfret was an English clergyman, rector of Maulden in Bedfordshire, son of the vicar of Luton in the same county. The story is preserved by Johnson that the bishop of London stopped him in some church preferment because in his *Choice* he declared that he would have no wife, although he expressed a wish for the occasional company of a modest and sprightly young lady. The poet was married in real life all the same, and, while waiting in London to clear up a misunderstanding caused by the paganism of his poetry—the bishop apparently thinking that he had openly preferred a mistress to a wife—he caught small-pox and died at the age of thirty-five. Of his poetry Johnson happily says, "He pleases many; and he who pleases many must have some species of merit."

POMONA, the old Roman goddess of tree-fruits (*poma*). Ovid (*Met.*, xiv. 623 sq.) tells how she was loved by the sylvan deities, the satyrs, pans, etc., and how Vertumnus, god of the turning year, wooed and won the shy goddess. Corresponding to Pomona there seems to have been a male Italian deity called Puemunus, who was perhaps identical with Vertumnus. At Rome Pomona had a special priest, the flamen Pomonalis, who ranked lowest among the fifteen flamens. About 12 miles from Rome on the way to Ostia there was a Pomonal, or place (perhaps grove) sacred to Pomona. She was also worshipped in the neighborhood of Amiternum.

POMPADOUR, JEANNE ANTOINETTE POISSON LE NORMANT D'ÉTIOLLES, MARQUISE DE (1721-1764), the most famous of all the mistresses of Louis XV., was born in Paris on 29th December, 1721, and was baptized as the legitimate daughter of François Poisson, an officer in the household of the duke of Orleans, and his wife Madeleine de la Motte, in the church of St. Eustache, but she was suspected, as well as her brother, afterwards Marquis of Marigny, to be the child of a very wealthy financier, and farmer-general of the revenues, Le Normant de Tournem. He at any rate took upon himself the charge of her education; and, as from the beauty and wit she showed from childhood she seemed to be born for some uncommon destiny, he declared her "un morceau de roi," and specially educated her to be a king's mistress. This idea was confirmed in her childish mind by the prophecy of an old woman, whom in after days she pensioned for the correctness of her prediction. In 1741 she was married to a nephew of her protector and guardian, Le Normant de Étiolles, who was passionately in love with her, and soon became a queen

of fashion. Yet the world of the financiers at Paris was far apart from the court world, where she wished to reign; she could get no introduction at court, and could only try to catch the king's eye when he went out hunting. But Louis XV. was then under the influence of Madame de Mailly, who carefully prevented any further intimacy with "la petite Étiolles," and it was not until after her death that the king met the fair queen of the financial world of Paris at a ball given by the city to the dauphin in 1744, and he was immediately subjugated. She at once gave up her husband, and in 1745 was established at Versailles as "maîtresse en titre." Louis XV. bought her the estate of Pompadour, from which she took her title of marquise. She was hardly established firmly in power before she showed that ambition rather than love had guided her, and began to mix in politics. Knowing that the French people of that time were ruled by the literary kings of the time, she paid court to them, and tried to play the part of a Mæcenas. Voltaire was her poet in chief, and the founder of the physiocrats, Quesnay, was her physician. In the arts she was even more successful; she was herself no mean etcher and engraver, and she encouraged and protected Vanloo, Boucher, Vien, Greuze, and the engraver Jacques Guay. Yet this policy did not prevent her from being lampooned, and the famous Poissardes against her contributed to the ruin of many wits suspected of being among the authors, and notably of the Comte de Maurepas. The command of the political situation passed entirely into her hands; she it was who brought Belle-Isle into office with his vigorous policy; she corresponded regularly with the generals of the armies in the field, as her recently published letters to the Comte de Clermont prove; and she introduced the Abbé de Bernis into the ministry in order to effect a very great alteration of French politics in 1756. The continuous policy of France since the days of Richelieu had been to weaken the house of Austria by alliances in Germany; but Madame de Pompadour changed this hereditary policy because Frederick the Great wrote scandalous verses on her; and because Maria Theresa wrote her a friendly letter she entered into an alliance with Austria. This alliance brought on the Seven Years' War with all its disasters, the battle of Rosbach and the loss of Canada; but Madame de Pompadour persisted in her policy, and when Bernis failed her, brought Choiseul into office, and supported him in all his great plans, the Pacte de Famille, the suppression of the Jesuits, and the peace of Versailles. But it was to internal politics that this remarkable woman paid most attention; no one obtained office except through her; in imitation of Madame de Maintenon she prepared all business for the king's eye with the ministers, and contrived that they should meet in her room; and she daily examined the letters sent through the post office with Janelle, the director of the post office. By this continuous labor she made herself indispensable to Louis. Yet, when she had lost the heart of her lover after a year or two, she had a difficult task before her; to maintain her influence she had not only to save the king as much trouble as possible, but to find him fresh pleasures. When he first began to weary of her, she remembered her talent for acting and her private theatricals at Étiolles, and established the "théâtre des petits cabinets," in which she acted with the greatest lords about the court for the king's pleasure in tragedies and comedies, operas and ballets. By this means and the "concerts spirituels" she kept in favor for a time; but at last she found a surer way, by encouraging the king in his debaucheries, and Louis wept over her kindness to his various mistresses. Only once, when the king was wounded by Damiens in 1757, did she receive a serious shock, and momentarily left the court; but on his recovery she returned more powerful than ever. She even ingratiated herself with the queen, after the example of Madame de Maintenon,

and was made a lady-in-waiting; but the end was soon to come. "Ma vie est un combat," she said, and so it was, with business and pleasure; she gradually grew weaker and weaker, and when told that death was at hand she dressed herself in full court costume, and met it bravely on 15th April, 1764, at the age of forty-two.

See Capefigue, *Madame la Marquise de Pompadour*, 1858; E. and J. de Goucourt, *Les Maîtresses de Louis XV.*, vol. II., 1860; and Campardon, *Madame de Pompadour et la Cour de Louis XV. au milieu du dix-huitième siècle*, 1867. Far more valuable are Malassis's two recently published volumes of correspondence, *Correspondance de Madame de Pompadour avec son père M. Poisson, et son frère M. de Vandières, etc.*, 1878, and Bonhomme, *Madame de Pompadour, général d'armée*, 1880, containing her letters to the Comte de Clermont. For her artistic and theatrical tastes see particularly J. F. Leturcq, *Notice sur Jacques Guay, Graveur sur pierres fines du Roi Louis XV.*; *Documents inédits émanant de Guay et notes sur les œuvres de gravure en taille douce et en pierres durs de la Marquise de Pompadour*, 1878; and Adolphe Julien, *Histoire du Théâtre de Madame de Pompadour, dit Théâtre des Petits Cabinets*, 1874.

POMPEII, an ancient town of Campania, situated on the shore of the Bay of Naples, almost immediately at the foot of Mount Vesuvius. To its proximity to that volcano it owes its celebrity—the peculiar circumstances of its destruction by the great volcanic outburst of Vesuvius in 79 A.D., and of its rediscovery in modern times, having converted that which would otherwise have been known only as an obscure country town into a place of world-wide fame, as one of the most interesting relics preserved to us from antiquity. Of its previous history comparatively little is recorded, but it appears that, like most other towns in the beautiful region in which it was situated, it had a population of a very mixed character, and it passed successively into the hands of several different nations, each of which probably contributed an additional element to its composition. Though its foundation was ascribed by Greek tradition to Heracles, in common with the neighboring city of Herculaneum, no value can be attached to these mythological or etymological fables; it is certain that it was not a Greek colony, in the proper sense of the term, as we know to have been the case with the more important cities of Cumæ and Neapolis. Strabo, in whose time it was a populous and flourishing place, tells us that it was first occupied by the Oscans, afterwards by the Tyrrhenians (i.e., Etruscans) and Pelasgians, and lastly, by the Samnites. The conquest of Campania by the last-mentioned people is an undoubted historical fact, and there can be no doubt that Pompeii shared the fate of the neighboring cities on this occasion, and afterwards passed in common with them under the yoke of Rome. But its name is only once mentioned during the wars of the Romans with the Samnites and Campanians in this region of Italy, and then only incidentally (Liv., ix. 38). At a later period, however, it took a prominent part in the outbreak of the nations of central Italy known as the Social War (91–89 B.C.), when it withstood a long siege by Sulla, and was one of the last cities of Campania that was reduced by the Roman arms. After that event the inhabitants were admitted to the Roman franchise, but a military colony was settled in their territory by the dictator Sulla, and there can be no doubt that the whole population became rapidly Romanized. Before the close of the republic it became a favorite resort of the leading nobles of Rome, many of whom acquired villas in the neighborhood. Among the most prominent of these was Cicero, whose letters abound with allusions to his Pompeian villa, which was one of his favorite places of occasional residence. The same fashion continued under the Roman empire, and there can be no doubt that during the first century after the Christian era, Pompeii, without rising above the rank of an ordinary provincial town, had become a flourishing place with a considerable population, for which it was indebted in part to its position at the mouth of the river Sarnus, which rendered it the port of the neighboring towns in the interior. But two events only are recorded of its history during this period. In 59 A.D. a tumult

took place in the amphitheatre of Pompeii between the citizens of the place and the visitors from the neighboring colony of Nuceria, which led to a violent affray, in which many persons were killed and wounded on both sides. The Pompeians were punished for this violent outbreak by the prohibition of all gladiatorial and theatrical exhibitions for ten years (Tacitus, *Ann.*, xiv. 17). A characteristic, though rude, painting, found on the walls of one of the houses, gives a representation of this untoward event.

Only four years afterwards (63 A.D.) a much more serious disaster befell the city. An earthquake, which affected all the neighboring towns, vented its force especially upon Pompeii, a large part of which, including most of the public buildings, was either destroyed or so seriously damaged as to require to be rebuilt rather than repaired (Tacit., *Ann.*, xv. 21; Seneca, *Q. N.*, vi. 1). The actual amount of the injuries sustained, which is intimated in general terms by Tacitus and Seneca, is more accurately known to us from the existing remains. For the inhabitants were still actively engaged in repairing and restoring the ruined edifices when the whole city was overwhelmed by a much more appalling catastrophe. In 79 A.D. the neighboring mountain of Vesuvius, the volcanic forces of which had been slumbering for unknown ages, suddenly burst into a violent eruption, which, while it carried devastation all around the beautiful gulf, buried the two cities of Herculaneum and Pompeii under dense beds of cinders and ashes. It is singular that, while we possess a detailed description of this famous eruption in two well-known letters of the younger Pliny (*Epist.* vi. 16, 20), he does not even notice the destruction of Pompeii or Herculaneum, though his uncle perished in the immediate neighborhood of the former city. But their unhappy fate is noticed by Dion Cassius, and its circumstances may be gathered with certainty from the condition in which it has been found. These were such as eminently to conduce to its preservation and interest as a relic of antiquity. Pompeii was not, like Herculaneum, buried in a solid mass of volcanic tuff, but merely covered with a bed of lighter substances, cinders, small stones, and ashes, thrown out by the volcano, and falling from above on the devoted city. It is clearly established that the whole of this superincumbent mass, though attaining to an average thickness of from 18 to 20 feet, was the product of one eruption—though the materials may be divided generally into two distinct strata, the one consisting principally of cinders and small volcanic stones (called in Italian "lapilli"), and the other and uppermost layer of fine white ash, often consolidated by the action of water from above, so as to take the moulds of objects contained in it like clay or plaster of Paris.

So completely was the unfortunate city buried under this overwhelming mass that its very site was forgotten, and even the celebrated topographer Cluverius in the 17th century was unable to fix it with certainty. This difficulty arose in part from the physical changes consequent on the eruption, and it was not till 1748 that an accidental discovery drew attention to its remains, and revealed the fact that beneath the vineyards and mulberry grounds which covered the site there lay entombed the ruins of a city, far more accessible, if not more interesting, than those (previously discovered) of the neighboring Herculaneum. It was not till 1755 that systematic excavations on the site were begun, and, though they were thenceforth carried on more or less continuously during the whole of that century, it was not till the beginning of the present century that they assumed a regular character, and the work, which had received a vigorous stimulus during the period of the French government (1806–1814), was prosecuted, though in a less methodical and systematic manner, under the succeeding rule of the Bourbon kings (1815–61). Of late years the process has been carried on, under the enlightened

direction of Signior Fiorelli, in a much more careful and scientific manner than before, and the results have been in many respects of the highest interest. At the same time the invention of photography has enabled the directors to preserve a far more satisfactory record of every step in the explorations than could previously be attempted.

It would be impossible for us to present our readers in this place with anything like an idea of the results of these excavations. Interesting as are the numerous works of art that have been brought to light, and important as is their bearing upon the history of some branches of ancient art, they cannot compare in interest with the flood of light which this marvellous discovery has thrown upon ancient life in all its details, enabling us to picture to ourselves the ways and manners and habits of life of a cultivated and flourishing population eighteen centuries ago, in a manner which no amount of study of ancient literature could possibly accomplish. We must confine ourselves in the present article chiefly to those points which bear more immediately on the topography and character of the town of Pompeii, referring our readers for other details to the numerous works in which they have been described and delineated.

The town was situated on a rising ground of small elevation, separated by a distance of less than a mile from the foot of the actual rise of the outer cone of Vesuvius. This eminence is itself undoubtedly due to an outflow of lava from that mountain, during some previous eruption in prehistoric times, for we know from Strabo that Vesuvius, though presenting in his time all the appearances of an extinct volcano, had been quiescent ever since the first records of the Greek settlements in this part of Italy. But the position of Pompeii in ancient times differed materially from that which it occupies at the present day. It was situated close to the sea-shore, from which it is now more than a mile distant, and adjoining the mouth of the river Sarnus or Sarno, which now enters the sea nearly two miles from its site, but the present course of this stream is due in part to modern alteration of its channel, as well as to the effects of the great eruption. It is certain, however, that in Strabo's time Pompeii owed much of its prosperity to its serving as the port of the adjoining plain, and the neighboring towns of Nuceria, Nola, and Acerræ (Strabo, v. c. 4, § 8).

The area occupied by the ancient city was of an irregular oval form, and about two miles in circumference. It was surrounded by a wall, which is still preserved around more than two-thirds of its extent, but no traces of this are found on the side towards the sea, and there is no doubt that on this side it had been already demolished in ancient times, so as to give room for the free extension of houses and other buildings in that direction. These walls are strengthened at intervals by numerous towers, which occur in some parts at a distance of only about 100 yards, but in general much less frequently. They are, however, of a different style of construction from the walls, and appear to have been added at a later period, probably that of the settlement of the Roman colony by Sulla. Similar evidences of the addition of subsequent defences are to be traced also in the case of the gates, of which no less than eight are found in the existing circuit of the walls. Some of these present a very elaborate system of defence, but it is evident from the decayed condition of others, as well as of parts of the walls and towers, that they had ceased to be maintained for the purposes of fortification long before the destruction of the city. The gates are now known by names given them in modern times from the direction in which they led, as, the gate of Herculaneum, of Stabiae, of Nola, etc. No trace has been found of their ancient appellations.

The general plan of the town is very regular, the streets being generally straight, and crossing one another at right angles or nearly so. But an exception is found in the street leading from the gate of Herculaneum to the forum, which, though it must have been

one of the principal thoroughfares in the city, was crooked and irregular, as well as very narrow, in some parts not exceeding 12 to 14 feet in width, including the raised *trottoirs* or footpaths on each side, which occupy a considerable part of the space, so that the carriage-way could only have admitted of the passage of one vehicle at a time. The other streets are in some cases broader, but rarely exceed 20 feet in width, and the broadest yet found is less than 30, while the back streets running parallel to the main lines are only about 15 feet. They are uniformly paved with large polygonal blocks of hard basaltic lava, fitted very closely together, though now in many cases marked with deep ruts from the passage of vehicles in ancient times. They are also in all cases bordered by raised *trottoirs* on both sides, paved in a similar manner; and for the convenience of foot passengers, these are connected from place to place by stepping-stones raised above the level of the carriage-way. Such an arrangement must have presented a considerable obstacle to the passage of vehicles; and altogether it is evident that the streets of Pompeii, like those of most Roman towns, were calculated much more for foot passengers than for any extensive traffic of wheeled carriages. In other respects they must have been far from presenting the lively aspect of the streets of modern and even mediæval towns, and must rather have resembled those of Oriental cities,—the living apartments all opening towards the interior, and showing only blank walls towards the street; while the windows were generally to be found only in the upper story, and were in all cases small and insignificant, without any attempt at architectural effect. In some instances indeed the monotony of their external appearance was broken by small shops, occupying the front of the principal houses, as it were let in to the main building; these were in some cases numerous enough to form a continuous *façade* to the street. This is seen especially in the case of the Street of Herculaneum, and that of Stabiae, both of which were among the principal and most frequented thoroughfares.

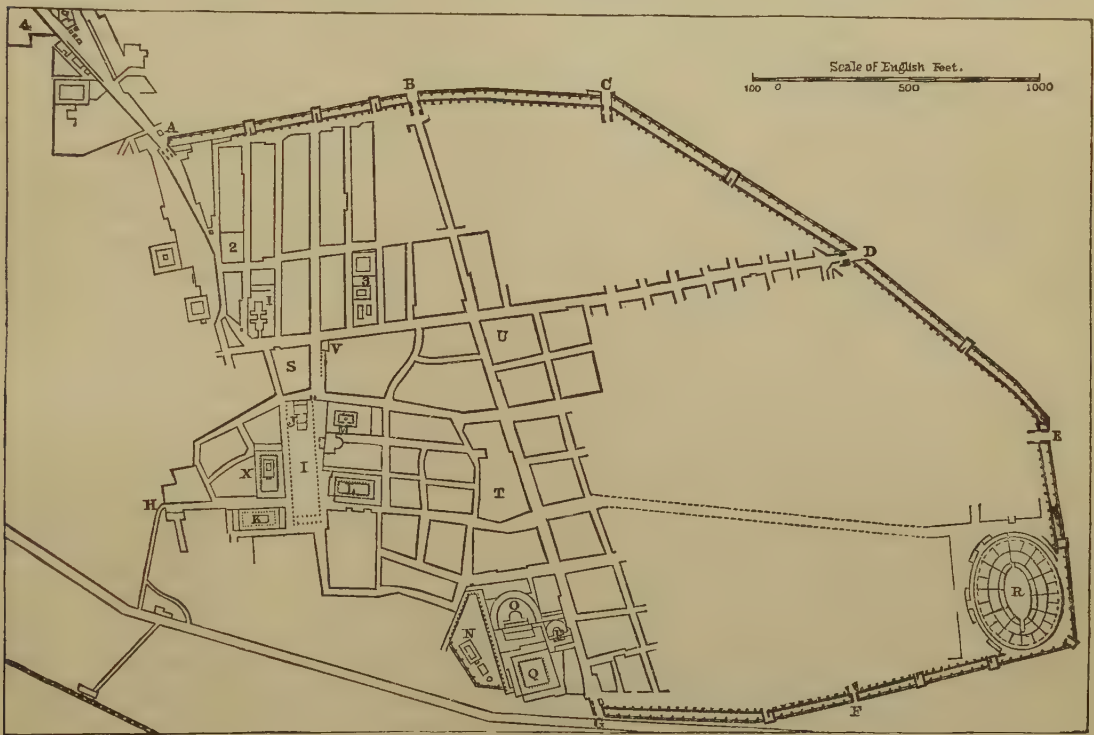

The former of these main lines of street, which, as already described, led from the gate of Herculaneum to the forum, was crossed, a little before it reached that important centre, by a long straight line of street, which led directly to the gate of Nola. Two other parallel lines of street struck off from the forum itself towards the east, and these have been followed as far as the points where they cross nearly at right angles another main line of street, which leads direct from the gate of Vesuvius to that of Stabiae, near the theatres, thus traversing the city in its whole width from north to south. Almost the whole portion of the city which lies to the west of this last line, towards the forum and the sea, has been more or less completely excavated; but the greater part of that on the other side of it remains still unexplored, with the exception of the amphitheatre, and a small space in its immediate neighborhood. Altogether it may be calculated that about two-fifths of the whole extent has been already excavated. But there can be little doubt that the portion already known is the most important, as it includes the forum, with the temples and the public buildings adjacent to it, the *thermæ*, theatres, amphitheatre, etc.

The forum was unquestionably at Pompeii, as at Rome itself, and in all other Italian cities, the focus and centre of all the life and movement of the city, and was at once the resort of the lounge and the gathering place of men of business. Hence it was surrounded on all sides by public buildings or edifices of a commanding character. It was not, however, of large size, as compared to the open spaces in modern towns, being only 160 yards in length by 35 in breadth. Nor was it a centre of traffic in the modern sense of the word, being only accessible to any description of wheeled carriages at one angle, and the nature of its pavement, composed

of broad flags of travertine, excluding the idea of its being intended for their passage. It was surrounded on three sides by a portico, or rather by a series of porticos, some supported on arcades, others in the Grecian manner on columns; and these porticos were originally surmounted by a gallery or upper story, traces of the staircases leading to which still remain, though the gallery itself has altogether disappeared. It is, however, certain from the existing remains that both this portico and the adjacent buildings had suffered severely from the earthquake of 63, and that they were undergoing a process of restoration, involving material changes in the original arrangements, which was still incomplete at the time of their final destruction.

The north end of the forum, where alone the portico is wanting, is occupied in great part by a building, the most imposing in the whole city, which is now generally known, on grounds that may be considered satisfactory, as the temple of Jupiter. It was raised on a *podium* or base of considerable elevation, and had a portico with six Corinthian columns in front, which, according to Sir W. Gell, are nearly as large as those

in the portico of St. Paul's. This magnificent edifice had, however, been evidently overthrown by the earthquake of 63, and is in its present condition a mere ruin. On each side of it were two arches, affording an entrance into the forum, but capable of being closed by iron gates. The principal of these, at the northeast angle of the forum, was the approach by which that open space was entered in coming from the gate of Herculaneum; the passage, however, was barred to wheeled carriages by a descent of three small steps. On the east side of the forum were four edifices, all of them unquestionably of a public character, but of which the names and attribution have been the subject of much controversy. The first (proceeding from the north) is generally known, though without doubt erroneously, as the Pantheon, or temple of the Twelve Gods; but it is very doubtful whether it is a temple at all, and the latest authorities are disposed to regard it as a *macellum* or meat-market, though the situation would seem to be unhappily chosen for such a purpose. Next to this comes a building generally regarded as the *curia* or *senaculum*—the meeting-place of the local senate, or town council.

3. House of the Faun.
4. Villa of Arrius Diomedes.

Beyond this comes another temple of small dimensions commonly called the temple of Mercury, but supposed also, on very slight grounds, to have been dedicated to Augustus; and beyond this again, bounded on the south by a street known as the Street of the Silversmiths, is a large and spacious edifice, which, as we learn from an extant inscription, was erected by a priestess named Eumachia. Notwithstanding this, its purpose and character are open to considerable doubt; but it resembles a basilica in its form and disposition, and was probably designed for similar purposes. The name of Chalcidicum, by which it is commonly known, is an erroneous

inference from the inscription just referred to. The south end of the forum is occupied by three small buildings of very similar form and arrangement, which are supposed to have served as courts of law, though their destination is a matter of much uncertainty; while the greater part of the west side is occupied by two large buildings,—a basilica, which is the largest edifice in Pompeii, and a temple, which presents its side to the forum, and hence fills up a large portion of the surrounding space. The former, as we learn from an inscription on its walls, was anterior in date to the consulship of M. Lepidus and Q. Catulus (78 B.C.), and therefore belongs to the

Oscan period of the city, before the introduction of the Roman colony. The temple was an extensive edifice, having a comparatively small *cella*, raised upon a *podium*, and standing in the midst of a wide space surrounded by a portico of columns, outside which again is a wall, bounding the sacred enclosure. It is commonly called the temple of Venus, but without any evidence; the most recent authorities regard it, on somewhat better grounds, as dedicated to Apollo. Between this temple and the basilica a street of unusual width leads off direct to the gate which opens towards the sea, and is still preserved, though the walls on this side of the city have ceased to exist.

Besides the temples which surrounded the forum, the remains of four others have been discovered, three of which are situated in the immediate neighborhood of the theatres. Of these by far the most interesting, though the least perfect, is one which is commonly known as the temple of Hercules (an appellation wholly without foundation), and which is not only by far the most ancient edifice in Pompeii, but presents us with all the characters of a true Greek temple, resembling in its proportions that of Neptune at Pæstum, and probably of as remote antiquity. Unfortunately only the basement and a few capitals and other architectural fragments remain, and, though these suffice to enable us to restore its plan and design, of course its effect as a monument is wholly lost. The period of its destruction is unknown, for it appears certain that it cannot be ascribed wholly to the earthquake of 63. On the other hand the reverence attached to it in the later periods of the city is evidenced by its being left standing in the midst of a triangular space adjoining the great theatre, which is surrounded by a portico, so as to constitute a kind of forum, though scarcely deserving that appellation. In the immediate neighborhood of the preceding, and close to the great theatre, stood a small temple, which, as we learn with certainty from the inscription still remaining, was dedicated to Isis, and was restored, or rather rebuilt, by a certain Popidius Celsinus, after the original edifice had been reduced to ruin by the great earthquake of 63. Though of small size, and by no means remarkable in point of architecture, this is interesting as the only remaining temple dedicated to the Egyptian goddess, whose worship became so popular under the Roman empire. There is nothing peculiar in the arrangements of the building itself, but a small edifice within the sacred enclosure, to which nothing similar was found in any other instance, was doubtless in some way connected with the peculiar rites of the mysterious deity. Close to this temple was another, of very small size, and of little interest, commonly known as the temple of Æsculapius, but by others supposed to have been dedicated to Jupiter and Juno. No real foundation exists for either attribution. More considerable and important was a temple which stood at no great distance from the forum, at the point where the street leading thither from the gate of Herculaneum was crossed by the wide line of thoroughfare leading to the gate of Nola. We learn from an inscription that this was dedicated to the Fortune of Augustus (*Fortuna Augusta*), and was erected, wholly at his own cost, by a citizen of the name of M. Tullius, unfortunately no connection of the orator. This temple appears to have suffered very severely from the earthquake, and at present affords little evidence of its original architectural ornament; but we learn from existing remains that its walls were covered with slabs of marble, and that the columns of the portico were of the same valuable material.

All the temples above described, except that ascribed to Hercules, agree in being raised on an elevated *podium* or *amentum*,—an arrangement usual with all similar buildings of Roman date. Neither their materials nor the style of their architecture exceeds what might reasonably be expected in a second-rate provincial town; and the same may be said in general of the

other public buildings. Among these the most conspicuous are the theatres, of which there were two, placed, as was usual in Greek towns, in close juxtaposition with one another. The largest of these, which was partly excavated in the side of the hill, was a building of considerable magnificence, being in great part cased with marble, and furnished with seats of the same material, which have, however, been almost wholly removed. Its internal construction and arrangements resemble those of the Roman theatres in general, though with some peculiarities that show Greek influence, and we learn from an inscription that it was erected in Roman times by two members of the same family, M. Holconius Rufus and M. Holconius Celer, both of whom held important municipal offices at Pompeii during the reign of Augustus. It appears, however, from a careful examination of the remains that their work was only a reconstruction of a more ancient edifice, the foundations of which, and some other portions, may be distinctly traced. The smaller theatre, which was erected, as we learn from an inscription, by two magistrates specially appointed for the purpose by the decurions of the city, was of older date than the large one, and appears to have been constructed about the same time as the amphitheatre, soon after the establishment of the Roman colony under Sulla. From the same source we learn that it was permanently covered—a rare thing with Roman theatres; but in the case of the larger theatre also the arrangements for the occasional extension of an awning (*velarium*) over the whole are distinctly found. The smaller theatre is computed to have been capable of containing fifteen hundred spectators, while the larger could accommodate five thousand persons.

Adjoining the theatres is a large rectangular enclosure, surrounded by a portico, the purpose of which has been the subject of considerable controversy, but it is now generally admitted to have been the quarters or barracks of the gladiators, who were permanently maintained in the city with a view to the shows in the amphitheatre. It is singular that it should have been at so considerable a distance from that building, which is situated at the southeastern angle of the town, above 500 yards from the theatres. The amphitheatre was erected by the same two magistrates who built the smaller theatre, at a period when no permanent edifice of a similar kind had yet been erected in Rome itself. But apart from its early date it has no special interest, and is wholly wanting in the external architectural decorations that give such grandeur of character to similar edifices in other instances. Being in great part excavated in the surface of the hill, instead of the seats being raised on arches, it is wanting also in the picturesque arched corridors which contribute so much to the effect of those other ruins. Nor are its dimensions (430 feet by 335) such as to place it in the first rank even of provincial structures of this class, though it may still strike a visitor of the present day as surprisingly large for a town of the population of Pompeii. But, as we learn from the case of their squabble with the people of Nuceria, the games celebrated in the amphitheatre on grand occasions would be visited by large numbers from the neighboring towns.

Adjoining the amphitheatre was found a large open space, nearly square in form, which has been supposed to be a forum boarium or cattle market, but, no buildings of interest being discovered around it, the excavation was filled up again, and this part of the city has not been since examined.

Among the more important public buildings of Pompeii were the *thermæ*, or public baths, an institution that always held a prominent position in every Roman or Græco-Roman town. Three different establishments of this character have been discovered, of which the first, excavated in 1824, was for a long time the only one known. Though the smallest of the three, it is in some respects the most complete and interesting; and it was until of late years the principal source from

which we derived our knowledge of this important branch of the economy of Roman life. The vast series of edifices known by the name of *thermæ* at Rome, as well as those in other provincial towns, are in such a state of ruin as to throw little light upon the details of their arrangements. At Pompeii on the contrary the baths are so well preserved as to show at a glance the purpose of all the different parts—while they are among the most richly decorated of all the buildings in the city. We trace without difficulty all the separate apartments that are described to us by Roman authors, the *apodyterium*, *frigidarium*, *tepidarium*, *caldarium*, etc., together with the apparatus for supplying both water and heat, the places for depositing the bather's clothes, and other minor details which were for the first time revealed to us by the discovery of these interesting buildings. It is obviously impossible for us in this place to enter into a detailed description of these arrangements, for which we must refer our readers to the professed treatises on Roman antiquities, as well as to the larger works on Pompeii (see also BATHS, vol. iii. p. 376). The greater *thermæ*, which were not discovered till 1857, nor fully excavated till 1860, so that they are not described in the earlier works on the subject, are on a much more extensive scale than the others, and combine with the special purposes of the building a *palæstra* and other apartments for exercise or recreation. The arrangements of the baths themselves are, however, almost similar to those of the lesser *thermæ*. In this case an inscription records the repair and restoration of the edifice after the earthquake of 63, but the period of its original construction is unknown. It appears, however, that these two establishments were found inadequate to supply the wants of the inhabitants, and a third edifice of the same character, but on a still more extensive scale, was in course of construction when the town was overwhelmed. The remains of this, which were first discovered and excavated in 1877, are, however, of comparatively little interest from the incomplete state in which the buildings were left.

Great as is the interest attached to the various public buildings of Pompeii, and valuable as is the light that they have in some instances thrown upon similar edifices in other ruined cities, far more curious and interesting is the insight afforded us by the numerous private houses and shops into the ordinary life and habits of the population of an ancient town. In this respect Pompeii stands alone, among all antiquarian discoveries,—the difficulties of exploration at Herculaneum having greatly checked all further investigations on that equally promising site. But here again it is impossible in an article like the present to do more than briefly advert to the general results of the excavations (compare ARCHITECTURE, vol. ii. p. 368–369 and Pl. XVII.). The houses at Pompeii are generally low, rarely exceeding two stories in height, and it appears certain that the upper story was generally of a slight construction, and occupied by small rooms, serving as garrets, or sleeping places for slaves, and perhaps for the females of the family. From the mode of destruction of the city these upper floors were in most cases crushed in and destroyed, and hence it was long believed that the houses for the most part had but one story; but recent researches have in many cases brought to light incontestable evidence of the existence of an upper floor, and the frequent occurrence of a small staircase is in itself sufficient proof of the fact. The windows, as already mentioned, were generally small and insignificant, and contributed nothing to the external decoration or effect of the houses. In some cases they were undoubtedly closed with glass, but its use appears to have been by no means general. The principal living rooms, as well as those intended for the reception of guests or clients, were all on the ground floor, the centre being formed by the *atrium*, or hall, which was almost always open above to the air, and in the larger houses was generally surrounded by col-

umns. Into this opened other rooms, the entrances to which seem to have been rarely protected by doors, and could only have been closed by curtains. All the apartments and arrangements described by Vitruvius and other ancient writers may be readily traced in the houses of Pompeii, and in many instances these have for the first time enabled us to understand the technical terms and details transmitted to us by Latin authors. We must not, however, hastily assume that the examples thus preserved to us by a singular accident are to be taken as representing the style of building in all the Roman and Italian towns. We know from Cicero that Capua was remarkable for its broad streets and wide-spread buildings, and it is probable that the Campanian towns in general partook of the same character. At Pompeii indeed the streets were not wide, but they were straight and regular, and the houses of the better class occupied considerable spaces, presenting in this respect no doubt a striking contrast, not only with those of Rome itself, but with those of many other Italian towns, where the buildings would necessarily be huddled together from the circumstances of their position. Even at Pompeii itself, on the west side of the city, where the ground slopes somewhat steeply towards the sea, houses are found which consisted of three stories or more.

The excavations systematically conducted for many years past have presented us with examples of houses of every description, from the humble dwelling-place of the artisan or proletarian, with only three or four small rooms, to the stately mansions of Sallust and Pansa,¹—the last of which is the most regular as well as the most extensive of all, and may be taken as an almost perfect model of a complete Roman house of a superior class. But the general similarity in their plan and arrangement is very striking, and in all those that rise above a very humble class the leading divisions of the interior, the *atrium*, *tablinum*, *peristyle*, etc., may be traced with unfailing regularity. Another peculiarity that is found in all the more considerable houses in Pompeii is that of the front, where it faces one of the principal streets, being occupied with shops, usually of small size, and without any communication with the interior of the mansion. In a few instances indeed such a communication is found, but in these cases it is probable that the shop was used for the sale of articles grown upon the estate of the proprietor, such as wine, fruit, oil, etc., a practice that is still common in Italy. In general the shop had a very small apartment behind it, and probably in most cases a sleeping chamber above it, though of this the only remaining evidence is usually a portion of the staircase that led to this upper room. The front of the shop was open to the street, but was capable of being closed with wooden shutters, the remains of which have in a few instances been preserved. Of course it is only in a few cases that the particular purpose of the shop or trade of its owner can be determined, though, from the exceptional manner of their preservation, this can be done more frequently than might be expected. Thus not only have the shops of silversmiths been recognized by the precious objects of that metal found in them, but large quantities of fruits of various kinds preserved in glass vessels, various descriptions of corn and pulse, loaves of bread, moulds for pastry, fishing-nets, and many other objects, too numerous to mention, have been found in such a condition as to be identified without difficulty. Cooks' shops appear to have been numerous, as well as *thermopolia*, where hot drinks were sold. Bakers' shops are also frequent, though arrangements for grinding and baking appear to have formed part of every large

¹ It may be observed that the names given in most cases to the houses are either arbitrary, or founded in the first instance upon erroneous inferences. Hence they are frequently changed, and great confusion arises in consequence in comparing the different works on the subject. A few only of the best known may be considered as established by long usage, among which are the two here referred to.

family establishment. In other cases, however, these were on a larger scale, provided with numerous querns or hand-mills of the well-known form, evidently intended for public supply. Another establishment on a large scale was a *fullonica* or fuller's shop, where all the details of the business were illustrated by paintings still visible on the walls. A dyer's shop, a tannery, and a shop where colors were ground and manufactured—an important business where almost all the rooms of every house were painted—are of special interest, as is also the house of a surgeon, where numerous surgical instruments were found, some of them of a very ingenious and elaborate description, but all made of bronze. Another curious discovery was that of the abode of a sculptor, containing his tools, as well as blocks of marble and half-finished statues. The number of utensils of various kinds found in the houses and shops is almost endless, and, as these are in most cases of bronze, they are generally in perfect preservation.

Of the numerous works of art discovered in the course of the excavations the statues and large works of sculpture, whether in marble or bronze, are inferior to those found at Herculaneum, but some of the bronze statuettes are of exquisite workmanship, while the profusion of ornamental works and objects in bronze and the elegance of their design, as well as the finished beauty of their execution, are such as to excite the utmost admiration,—more especially when it is considered that these are the casual results of the examination of a second-rate provincial town. The same impression is produced in a still higher degree by the paintings with which the walls of the private houses, as well as those of the temples and other public buildings, are adorned, and which are not merely of a decorative character, but in many instances present us with elaborate compositions of figures, historical and mythological scenes, as well as representations of the ordinary life and manners of the people, which are full of interest to us, though often of inferior artistic execution. An illustration of the character of the Pompeian wall-paintings is given in the article MURAL DECORATION, vol. xvii. p. 48, Fig. 8. Our knowledge of ancient painting is indeed derived to a much greater extent from Pompeii than from all other sources whatever; and when we contemplate the variety and beauty of what we find here entombed, we cannot but ask ourselves what would have been the result had a great and opulent city like Capua or Naples been preserved to us in the same manner as the comparatively insignificant Pompeii. The same character of elaborate decoration, guided almost uniformly by good taste and artistic feeling, is displayed in the mosaic pavements, which in all but the humbler class of houses frequently form the ornament of their floors. One of these, well known as the battle of Alexander, presents us with the most striking specimen of artistic composition that has been preserved to us from antiquity (see MOSAIC, vol. xvi. p. 878, where part of this composition is shown in Fig. 2).

The architecture of Pompeii must be regarded as presenting in general a transitional character from the pure Greek style to that of the Roman empire. The temples (as already observed) have always the Roman peculiarity of being raised on a *podium* of considerable elevation; and the same characteristic is found in most of the other public buildings. All the three orders of Greek architecture—the Doric, Ionic, and Corinthian—are found freely employed in the various edifices of the city, but rarely in strict accordance with the rules of art in their proportions and details; while the private houses naturally exhibit still more deviation and irregularity. In many of these indeed we find varieties in the ornamentation, and even in such leading features as the capitals of the columns, which remind one rather of the vagaries of mediæval architecture than of the strict rules of Vitruvius or the monotonous regularity of Greek edifices. One practice which is

especially prevalent, so as to strike every casual visitor, is that of filling up the flutings of the columns for about one-third of their height with a thick coat of stucco, so as to give them the appearance of being smooth columns without flutings below, and only fluted above. The displeasing effect of this anomalous arrangement is greatly aggravated by the lower part of each column being almost always colored with red or yellow ochre, so as to render the contrast between the two portions still stronger. The architecture of Pompeii suffers also from the inferior quality of the materials generally employed. No good building stone was at hand; and the public as well as private edifices were constructed either of volcanic tuff, or brick, or the irregular masonry known to the Romans as *opus incertum*. Those which belong to the earlier or Oscan period of the city (before the establishment of the Roman colony) are for the most part of the former material, while those erected under the Roman empire, and especially those subsequent to the great earthquake of 63, are generally of slighter construction, and of a less durable character. In the private houses even the columns are mostly of brick, covered merely with a coat of stucco. In a few instances only do we find them making use of a kind of travertine, found in the valley of the Sarno, which, though inferior to the similar material so largely employed at Rome, was better adapted than the ordinary tuff for purposes where great solidity was required. The portion of the portico surrounding the forum which was in the process of rebuilding at the time when the city was destroyed was constructed of this material, while the earlier portions, as well as the principal temples that adjoined it, were composed in the ordinary manner of volcanic tuff. Marble appears to have been scarce, and was sparingly employed. In some instances where it had been freely introduced, as in the great theatre, it would seem that the slabs must have been removed at a period subsequent to the entombment of the city.

Outside the gate leading to Herculaneum is found a house of a different character from all the others, which from its extent and arrangements was undoubtedly a suburban villa, belonging to a person of considerable fortune. It is called—as usual without any authority—the villa of Arrius Diomedes; but its remains are of peculiar interest to us, not only for comparison with the numerous ruins of similar buildings which occur elsewhere,—often of greater extent, but in a much less perfect state of preservation,—but as assisting us in understanding the description of ancient authors, such as Vitruvius and Pliny, of the numerous appurtenances frequently annexed to houses of this description. The remains of a still more extensive suburban house which were discovered in 1764, and to which the name was given, without the slightest foundation, of the villa of Cicero, are no longer visible, having been covered up again with earth (as was frequently done in the last century) after the works of art had been removed.

In the vaulted corridors of the first villa were discovered no less than seventeen skeletons of the unfortunate inhabitants, who had evidently fled thither for protection. Almost all the skeletons and remains of bodies found in the city were discovered in similar situations, in cellars or underground apartments,—those who had sought refuge in flight having apparently for the most part escaped from destruction, or having perished under circumstances where their bodies were easily recovered by the survivors. According to Dion Cassius, a large number of the inhabitants were assembled in the theatre at the time of the catastrophe, but no bodies have been found there, and they were probably sought for and removed shortly afterwards. Hence the whole number of such remains discovered is not so large as might at first be supposed. It cannot indeed be accurately estimated, the records of the excavations in the last century having been very imperfectly kept; but the total number as yet discov-

ered can scarcely exceed three hundred. Of late years it has been found possible in many cases to take casts of the bodies found—a complete mould having been formed around them by the fine white ashes, partially consolidated by water.

The road leading from the gate of Herculaneum towards that city is bordered on both sides for a considerable extent by rows of tombs, as was the case with all the great roads leading into Rome, and indeed in all large Roman towns. Without of course approximating to the stately structures that adorned the Via Appia or Latina, these tombs are in many instances monuments of considerable pretension, and of a highly ornamental character, and naturally present in the highest degree the peculiar advantage common to all that remains of Pompeii, in their perfect preservation. Hardly any scene even in this extraordinary city is more striking than the *coup d'œil* of this long street of tombs, preserving uninjured the records of successive generations eighteen centuries ago. Unfortunately the names are all otherwise unknown; but we learn from the inscriptions that they are for the most part those of local magistrates and municipal dignitaries of Pompeii.

There appears to have been in the same quarter a considerable suburb, outside the gate, extending on each side of the road towards Herculaneum, apparently much resembling those which are now found throughout almost the whole distance from thence to Naples. It appears to have been known by the name of Pagus Augustus Felix.

No manuscripts have been discovered in Pompeii. Inscriptions have naturally been found in considerable numbers, and we are indebted to them for much information concerning the municipal arrangements of the town, as well as the construction of various edifices and other public works. The most interesting of these are such as are written in the Oscan dialect, which appears to have continued in official use down to the time when the Roman colony was introduced by Sulla. From that time the Latin language was certainly the only one officially employed, though Oscan may have still been spoken by a portion at least of the population. Still more curious, and almost peculiar to Pompeii, are the numerous writings scratched or rudely painted upon the walls, which have in some instances a semi-public character, such as recommendations of candidates for municipal offices, but more frequently are the mere expression of individual impulse and feeling, not uncommonly conveyed in rude and imperfect verses. In one house also a whole box was found filled with written tablets—diptychs and triptychs—containing the record of the accounts of a banker named L. Cæcilius Jucundus.

The inscriptions of a more formal character have been published by Mommsen, first in his *Inscriptiones Regni Neapolitani Latine* (fol., Leipsic, 1852) and again in the tenth volume of the great *Corpus Inscriptionum Latinarum*, published at Berlin (1883). The fourth volume of the same work published in 1871 contains all the scratched and written inscriptions discovered up to that date, edited by Zangemeister (under the title *Inscriptiones Parietarie Pompeianæ, Herculaneenses, et Stabianæ*); but the number has been since greatly increased, and a supplementary volume is in the press. The Oscan inscriptions, which are not comprised in the above collections, have been published by Fiorelli.

Most of the movable objects from Pompeii are now in the Museo Borbonico at Naples (see vol. xvii. p. 196).

Of the numerous works devoted to the antiquities and description of Pompeii generally it must suffice to mention a few. The earlier works, especially that of Mazois (*Les Ruines de Pompeii*, with its continuation by Gau, 4 vols. fol., Paris, 1812-33), and the two well-known works of Sir W. Gell (*Pompeiana*, 1st series, 2 vols. 8vo, London, 1824, 2d series, 1830), are still valuable for reference, though neces-

sarily very imperfect. The popular treatise published by the Society for Useful Knowledge (*Pompeii*, 2 vols. 8vo, London, 1831) gives a good account of what had been then discovered, and the light thrown by it on ancient manners and customs. The more recent works of Breton (*Pompeia*, 8vo, Paris, 1855) and of Mr. Dyer (*Pompeii: its History, Buildings, and Antiquities*, 8vo, London, 1867) bring down the record to a later period; and the successive editions of Overbeck's *Pompeii* (first published in 1856) have been kept continually on a par with the progress of discovery and research. The last edition of this valuable treatise (1884) is much the most complete and useful compendium of the whole subject that has yet appeared, and will supply all the wants of the ordinary reader. More special students will find there detailed references to the official records of the later discoveries that have been made under the direction of Signor Fiorelli, and to the numerous dissertations to which they have given rise. The great illustrated works of Zahn (Berlin, 1827-29) and Presuhn (fol., Leipsic, 1882) will furnish more elaborate representations of the decorative works with which almost all the buildings are adorned, while the student of ancient art may have recourse to the less ambitious collection of the ancient paintings by Helbig (*Wandgemälde der von Vesuv verschütteten Städte Campaniens*, Leipsic, 1868), with a supplementary volume published by Sogliano at Naples. A complete catalogue of all the works concerning Pompeii and Herculaneum will be found in a little book published at Milan in 1879 under the title of *Bibliotheca Pompeiana*. Unfortunately all works are rendered imperfect within a few years by the continued progress of the explorations and discoveries on the site.

(E. H. B.)

POMPEY is the common English form of the Roman name Pompeius.

I. CNEIUS POMPEIUS MAGNUS (106-48 B.C.), the great triumvir, whose name we always associate with Cæsar and Crassus, may be said to have led a soldier's life from his boyhood to his death. Born in 106 B.C., he fought by his father's side when a stripling of seventeen in the social or Italian War on the side of Sulla against the party of Marius and Cinna. Thus early in life he connected himself with the cause of the aristocracy, and a decisive victory which he won in 83 over the Marian armies gained for him from Sulla the title of "imperator." He followed up his successes in Italy by defeating the Marians in Sicily and Africa, and on his return to Rome in 81, though he was still merely an "eques" and not legally qualified to celebrate a triumph, he was allowed by general consent to enjoy this great distinction, while Sulla greeted him with the surname of Magnus, a title he always retained and handed down to his sons. Yet in 79 he used his influence in getting elected to the consulship a man politically opposed to Sulla, Æmilius Lepidus, who threatened Rome with another revolution and civil war in the interest of the democratic party. Pompey, however, at this crisis was loyal to his friends, and with the defeat of Lepidus the danger passed away. With some fears and misgivings the senate permitted him to retain the command of his victorious army, and decided on sending him to Spain, where, under a leader of singular ability, Sertorius, the Marian party was still formidable. Pompey was fighting in Spain from 76 to 71, and though at first he met with serious reverses he was ultimately successful, his great opponent, Sertorius, having, it would seem, lost the confidence of some of the native Spanish tribes. In 71 he was again in Italy at the head of his army, and won fresh glory by giving a finishing blow to the slave insurrection of Spartacus. That same year, amid great popular enthusiasm, but without the hearty concurrence of the senate, whom he had alarmed by talking of restoring the dreaded power of the tribunes, and though still merely an "eques," he was elected with Crassus to the consulship, and entered Rome in triumph for his Spanish victories. The following year saw the work of Sulla undone; the tribuneship was restored, and the administration of justice was no longer left exclusively to the senate, but was to be shared by them with the wealthier portion of the middle class, the "knights," as from old time they had been called, and the farmers and col-

lectors of the revenue. The change was really necessary, as the provincials could never get justice from a court composed of senators, and it was carried into effect by Pompey with Cæsar's aid. Pompey as a matter of course rose still higher in popularity, and on the motion of the tribune Gabinius in 67 he was entrusted with an extraordinary command over the greater part of the empire, specially for the extermination of piracy in the Mediterranean, by which the corn supplies of Rome were seriously endangered, while high prices of provisions caused great distress. It soon appeared that the right man had been chosen for the work: the price of corn fell immediately on Pompey's appointment, and in forty days the Mediterranean was swept from end to end and the pirates cleared out of its waters. Next year, on the proposal of the tribune Manilius, he had a yet further extension of his powers, the whole of Rome's empire in the East being put under his control for three years with the view of finally terminating the war with Mithradates, king of Pontus, who had recovered from the defeats he had sustained from Lucullus and regained his dominions. Both Cæsar and Cicero supported the tribune's proposal, which was easily carried in spite of the interested opposition of the senate and the aristocracy, several of whom held provinces which would now be practically under Pompey's command. Pompey was now by far the first man in the Roman world. His operations in the East were thoroughly successful, and, though no doubt he owed something to the victories of Læcullus, he showed himself an able soldier. The wild tribes of the Caucasus were cowed by the Roman arms, and the king of Pontus himself fled from Asia across the Black Sea to Panticapæum, the modern Kertch. In the years 64 and 63 Syria and Palestine were annexed to Rome's empire. After the capture of Jerusalem Pompey is said to have entered the temple, and even the Holy of Holies. Asia and the East generally were left under the subjection of petty kings who were mere vassals of Rome. Several cities had been founded which became centres of Greek life and civilization. A really great work had been accomplished, and Pompey, now in his forty-fifth year, returned to Italy in 61 to celebrate the most magnificent triumph which Rome had ever witnessed, and to be hailed as the conqueror of Spain, Africa, and Asia.

The remainder of Pompey's life is inextricably interwoven with that of Cæsar. He was married to Cæsar's daughter Julia, and as yet the relations between the two had been friendly. On more than one occasion Cæsar had supported Pompey's policy, which of late had been in a decidedly democratic direction. Pompey was now in fact ruler of the greater part of the empire, while Cæsar had only the two provinces of Gaul. The control of the capital, the supreme command of the army in Italy and of the Mediterranean fleet, the governorship of the two Spains, the superintendence of the corn supplies, which were mainly drawn from Sicily and Africa, and on which the vast population of Rome was wholly dependent, were entirely in the hands of Pompey. The senate and the aristocracy disliked and distrusted him, but they felt that, should things come to the worst, they might still find in him a champion of their cause. At the same time the senate itself was far from unanimous: among many of its members there was a feeling that a military imperialism had become a necessity, while to the rich and idle world generally peace and quiet at any price seemed the best of all blessings. Hence the joint rule of Pompey and Cæsar was not unwillingly accepted, and anything like a rupture between the two was greatly dreaded as the sure beginning of anarchy throughout the Roman world. With the death of Pompey's wife Julia, in 54, came strained relations between him and Cæsar, and soon afterwards he drew closer to what we may call the old conservative party in the senate and aristocracy. The end was

now near, and Pompey blundered into a false political position and an open quarrel with Cæsar. In 50 the senate by a very large majority revoked the extraordinary powers conceded to Pompey and Cæsar in Spain and Gaul respectively. Pompey's refusal to submit gave Cæsar a good pretext for declaring war and marching at the head of his army into Italy. At the beginning of the contest, the advantages were decidedly on the side of Pompey, but very speedily the superior political tact of his rival, combined with extraordinary promptitude and decision in following up his blows, turned the scale against him. Pompey's cause, with that of the senate and aristocracy, was finally ruined by his defeat in 48 in the neighborhood of the Thessalian city Pharsalus. That same year he fled with the hope of finding a safe refuge in Egypt, but was treacherously murdered as he was stepping on the shore by one of his old centurions. He had just completed his fifty-eighth year.

Pompey, though he had some great and good qualities, hardly deserved his surname of "the Great." He was certainly a very good soldier, and is said to have excelled in all athletic exercises, but he fell short of being a first-rate general. He won great successes in Spain and more especially in the East, but for these he was no doubt partly indebted to what others had already done. Of the gifts which make a good statesman he had really none. As plainly appeared in the last years of his life, he was too weak and irresolute to choose a side and stand by it. Pitted against such a man as Cæsar, he could not but fail. But to his credit be it said that in a corrupt time he never used his opportunities for plunder and extortion, and his domestic life was pure and simple.

A very complete life of Pompey will be found in Smith's *Dict. of Greek and Roman Biography*. The allusions to him in Cicero's works are very frequent.

II. **SEXTUS POMPEIUS MAGNUS** (75-35 B.C.), the younger son of Pompey the Great, born 75 B.C., continued after his father's death to prolong the struggle against the new rulers of the Roman empire. Cæsar's victory at Munda in 45 drove him out of Corduba (Córdoba), though for a time he held his ground in the south of Spain, and defeated Asinius Pollio, the governor of the province. In 43, the year of the triumvirate of Octavius, Antony, and Lepidus, he was proscribed along with the murderers of Cæsar, and not daring to show himself in Italy he put himself at the head of a fleet manned chiefly by slaves or proscribed persons, by means of which he made himself master of Sicily, and from thence ravaged the coasts of Italy. Rome was threatened with a famine, as the corn supplies from Egypt and Africa were cut off by his ships, and it was thought prudent to negotiate a peace with him, which was to leave him in possession of Sicily, Sardinia, and Achaia, provided he would allow Italy to be freely supplied with corn. But the arrangement could not be carried into effect, as Sextus renewed the war and gained some considerable successes at sea. However, in 36 his fleet was defeated and destroyed by Agrippa off the north coast of Sicily, and in the following year he was murdered at Mitylene by an officer of Antony. He had his father's bravery as a soldier, but seems to have been a rough uncultivated man. (W. J. B.)

PONCE DE LEON, LUIS. See **LEON, LUIS PONCE DE**.

PONCELET, JEAN VICTOR (1788-1867), mathematician, was born at Metz, July 1, 1788. From 1808 to 1810 he attended the Polytechnic School, and afterwards, till 1812, the Practical School at Metz. He then became lieutenant of engineers, and took part in the Russian campaign, during which he was taken prisoner and was confined at Saratoff on the Volga. It was during his imprisonment here that "privé de toute espèce de livres et de secours, surtout distrait par les malheurs de ma patrie et les miens propres," as he himself puts it, he began his researches on projective geometry which led to his great treatise on that subject. This work, the *Traité des Propriétés Projectives des Figures*, which was published in 1822

(2d ed., 1865), is occupied with the investigation of the projective properties of figures, that is, such properties as are not altered by projection. In his investigation he employs the ideas of continuity, of homologous figures, and of reciprocal polars; and by means of these, without any analysis, he was able to establish all the known properties of lines and surfaces of the second degree, and to discover others unknown before. This work entitles Poncelet to rank as one of the greatest of those who took part in the development of the modern geometry of which Monge was the founder. From 1815 to 1825 he was occupied with military engineering at Metz; and from 1825 to 1835 he was professor of mechanics at the Practical School there. In 1826, in his *Mémoire sur les Roues Hydrauliques à Aubes Courbes*, he brought forward improvements in the construction of water-wheels, which more than doubled their efficiency. In 1834 he became a member of the Academy; from 1838 to 1848 he was professor to the faculty of sciences at Paris, and from 1848 to 1850 commandant of the Polytechnic School, where he effected a reform in the course of study. At the London International Exhibition in 1851 he had charge of the department of machinery, and wrote a report on the machinery and tools on view at that exhibition. He died December 22, 1867. Besides those referred to above, he wrote a number of works, and contributed many papers to *Crelle's Journal*, etc., on different branches of engineering and mathematics.

POND, JOHN (c. 1767–1836), astronomer-royal, was born about 1767 in London, where his father made a fortune in trade. He entered Trinity College, Cambridge, at the age of sixteen, but took no degree, his course being interrupted by severe pulmonary attacks which compelled a prolonged residence abroad. His travels extended from Lisbon to Constantinople and the Nile, and were turned to account for astronomical observation. In 1800 he settled at Westbury near Bristol, and began to determine star-places with a fine altitude and azimuth circle of $2\frac{1}{2}$ feet diameter by Troughton. His demonstration in 1806 (*Phil. Trans.*, xvi. 420) of a change of form in the Greenwich mural quadrant led to the introduction of astronomical circles at the Royal Observatory, and to his own appointment as its head. Elected a fellow of the Royal Society, February 26, 1807, he married and went to live in London in the same year, and in 1811 succeeded Maskelyne as astronomer-royal.

During an administration of nearly twenty-five years, Pond effected a reform of practical astronomy in England comparable to that effected by Bessel in Germany. In 1821 he began to employ the method of observation by reflection; and in 1825 he devised means (see *Mem. R. A. Soc.*, ii. 499) of combining two mural circles in the determination of the place of a single object, the one serving for direct and the other for reflected vision. (By an invention of Airy's, the same object is now attained with one instrument.) During Pond's term of office the instrumental equipment at Greenwich was completely changed, and the number of assistants increased from one to six. The superior accuracy of his determinations was due in part to his systematic attention to the errors of his instruments, in part to his plan of multiplying observations. During a prolonged controversy (1810–24), he consistently denied the reality of Brinkley's imaginary star-parallaxes (see his papers in *Phil. Trans.*, cviii. 477; cxiii. 53). Delicacy of health impeded his activity, and compelled his retirement in the autumn of 1835. He died at Blackheath, September 7, 1836, and was buried beside Halley in the churchyard of Lee. The Copley medal was conferred upon him in 1823, and the Lalande prize in 1817 by the Paris Academy, of which he was a corresponding member. He published eight folio volumes of *Greenwich Observations*, translated Laplace's *Système du Monde* (in 2 vols. 8vo., 1809), and contributed thirty-one papers to scientific collections. His catalogue of 1112 stars (1833) was of great value.

PONDICHERRI, chief settlement of the French possessions in the East Indies, situated on the Coromandel coast, in $11^{\circ} 56' N.$ lat. and $79^{\circ} 53' E.$ long.; it is 86 miles south of Madras, and is connected with the South Indian Railway system. The territory consists of three districts—Pondicherry, Villianur, and Bahur—comprising an area of 112 square miles, with a population in 1881 of 139,210. The town is divided into a European and a native quarter, separated from one another by a canal. The French first settled at Pondicherry in 1674; it was besieged four times by the British, the last time in 1793; but it was finally restored in 1816. On the whole the town is considered very salubrious; the purity of its water-supply is said to be unrivalled in any other town in southern India.

PONEVYEZH, a district town of Russia, in the government of Kovno, situated on the upper course of the Nemyeja river, and connected by rail with Libau on the northwest and with Dinaburg (80 miles distant) on the east. It is an old town which was almost totally destroyed by the pestilence of 1550, but was rebuilt and repopled owing to its advantageous situation on the highway to the Baltic. After having suffered severely from wars in the 17th and 18th centuries it was annexed to Russia on the third dismemberment of Poland, but had neither manufacturing nor commercial importance until it was brought into railway connection with Libau, with which seaport it now carries on some trade in agricultural produce. Its population (8070 in 1865) had in 1881 reached 15,030, of whom nearly one-half were Jews.

PONIATOWSKI, a family of Poland, the earliest member of which to acquire high distinction was STANISLAUS CIOLEK (1677–1762), regarding whose descent there are conflicting accounts,—some tracing it to the Lombard Counts Torelli, one of whom in the seventeenth century married a daughter of Albert of Poniatow, and added the name of Poniatowski to his own, which he changed to its equivalent in Polish, Ciolek, while others affirm that the name Poniatowski was adopted by one of two brothers from an estate which fell to his share, while it is also asserted that Stanislaus Ciolek was the natural son of Prince Sapieha, and was adopted by a Polish nobleman named Poniatowski (see Szymanowski, *Die Poniatowski*, Geneva, 1880). In any case he had sufficient influence and ability to insure his rapid promotion in the army of Charles XII., and as major-general at the battle of Poltava in 1709 was able by his self-command in facilitating the passage of the Dnieper to save the retreating army. In 1711 he was sent on a special embassy to Constantinople, when he succeeded in obtaining from the sultan a promise to send an army to aid Charles in the war with Russia; but on account of a change in the office of grand vizier the promise was never carried out. All possibility of undertaking a Russian invasion being therefore at an end, he was appointed by Charles governor of the duchy of Zweibrücken. After the death of Charles, he gave his adhesion to Augustus II., by whom he was in 1724 made grand treasurer of Lithuania, and in 1731 palatine of Mazovia. On the death of Augustus II. he sought to effect the promotion of Stanislaus Leszczynski to the throne, but ultimately he gave in his submission to Augustus III., and after holding under him several high offices was in 1752 appointed castellan of Cracow. He was the author of *Remarques d'un Seigneur Polonois sur l'Histoire de Charles XII. par Voltaire*, 1741, which was translated into English in the same year. He died in 1762, leaving by his marriage with Constance Princess Czartoryski four sons, the best known of whom was the second, STANISLAUS AUGUSTUS (1732–1798), king of Poland, born 17th January, 1732. Sent by Augustus III. to the court of Russia, he won the favor of the grand duchess Catherine, who succeeded to the

throne by the assassination of her husband, 9th July, 1762. Through her influence he was, 7th September, 1764, chosen king of Poland. For an account of his despicable and disastrous rule see POLAND (pp. 309–10). After signing his abdication, 25th November, 1795, he took up his residence at St. Petersburg, where he enjoyed a pension of 200,000 ducats paid jointly by Austria, Russia, and Prussia. He died unmarried, 12th February, 1798 (see *Mémoires Secrets inédits de Stanislas II. Auguste*, Leipsic, 1867, and De Mouy, *Correspondance inédite de Roi Stanislas-Auguste et de Madame Geoffrin*, Paris, 1875). Of the other sons of Stanislaus Poniatowski, Casimir (1721–1800), the eldest, was grand chamberlain of Poland and commander of the royal guard; Andrew (1735–1773) became an Austrian field marshal; and Michael (1736–1794) was ultimately promoted primate of Poland. JOSEPH ANTON (1762–1813), prince and marshal of France, son of Andrew Poniatowski was born at Warsaw, 7th May, 1762. At the age of sixteen he entered the service of Austria. After the resolution of the diet to reorganize the Polish army he was recalled and obtained the rank of major-general. On the outbreak of hostilities with Russia in 1792 he was made commander of the army defending central Poland. When the king his uncle acceded to the confederation of Targovitz he resigned his commission, but on the outbreak of the insurrection in 1794 he enrolled himself as a volunteer under Kosciuszko, although Kosciuszko had previously held inferior military rank to his own. In command of a division he had charge of the defence of the northern side of Warsaw, and after its capitulation he went to Vienna. In 1798 he returned to Warsaw, having obtained from the Prussians a portion of his confiscated estates. On the arrival of Napoleon at Warsaw, 19th December, 1806, Poniatowski accepted his invitation to become general of a national Polish army, which fired by the hope of national independence, gathered to the number of 27,000, to assist Napoleon in his Russian campaign. After the peace of Tilsit, 7th July, 1807, the duchy of Warsaw was created, and Poniatowski became minister of war. On the invasion of the duchy in 1809 he fought a desperate battle near the village of Raszyn, and, being permitted afterwards to retreat across the Vistula, invaded Galicia and compelled the Russians to evacuate Cracow. In Napoleon's campaigns he held the command of the Polish army corps, distinguishing himself at Smolensk, Borodino, and Leipsic, where he took 1,000 prisoners, and in token of his brilliant exploit was created by Napoleon a marshal of France the same evening. He was employed in covering the retreat from Leipsic, and while charging a column of Prussian infantry was wounded by a ball in the shoulder. When the enemy obtained possession of the suburbs he endeavored to join the main army by plunging into the Elster, but was fired upon and, enfeebled by wounds, was drowned, 19th October, 1813. JOSEPH (1816–1873), grandson of Casimir mentioned above, was born 4th February, 1816, at Rome. Entering the Tuscan service, he went in 1849 as minister of Tuscany to London. In 1850 he took up his residence in Paris, and becoming a naturalized citizen was in 1854 chosen a member of the French senate. In 1870 he removed to London, where he supported himself by teaching music. He was the composer of several operas. He died 3d July, 1873.

PONS, JEAN LOUIS (1761–1831), French astronomer, born at Peyre (Haut-Dauphiné), 24th December, 1761, received a place at the Marseilles observatory in 1789, and in 1819 became the director of the new observatory at Marlia near Lucca, which he left in 1825 for the observatory of the museum at Florence. Here he died October 14, 1831. Pons was famous as a comet-hunter, discovering between 1801 and 1827 thirty-seven of these bodies, one of which (discovered 26th November, 1818) is the famous comet named after Encke, who determined its orbit.

PONSARD, FRANÇOIS (1814–1867), French dra-

matist, was born at Vienne in Dauphiné on the 1st June, 1814. He was bred a lawyer, and his first performance in literature was a translation of *Manfred* (1837). But the first important, and indeed the most important, event of his life was the representation of his play *Lucrèce* at the Théâtre Français on the 1st April, 1843. This date is a kind of epoch in literary and dramatic history, because it has been supposed to mark a reaction against the romantic style of Dumas and Hugo. In reality, however, Ponsard was only a romantic of a somewhat tamer genius than those who had gone before him. It so happened that the tastes and capacities of the most popular actress of the day, Rachel, suited his style of drama, and this contributed greatly to his own popularity. He followed up *Lucrèce* with *Agnès de Méranie* (1846), *Charlotte Corday* (1850), and others. Ponsard accepted the empire, though with no very great enthusiasm, and received the post of librarian to the senate, which, however, he soon resigned, fighting a bloodless duel with a journalist on the subject. *L'Honneur et L'Argent*, one of his most successful plays, was acted in 1853, and he became an Academician in 1855. For some years he did little, but in 1866 he obtained great success with *Le Lion Amoureux*. He died a year later in Paris in July, 1867, soon after his nomination to the commandership of the Legion of Honor. His widow was pensioned. Ponsard is no doubt in some ways a remarkable dramatist. Unlike most men who have achieved considerable success on the stage, he did not overwrite himself, and most of his plays hold a certain steady level of literary and dramatic ability. But, as has been said, his popularity is in the main due to the fact that he found an actress ready to hand for his pieces, and that his appearance coincided with a certain public weariness of the grander but also more extravagant and unequal style of 1830.

PONTANUS, JOVIANUS (1426–1503), a famous Italian humanist and poet, was born in 1426 at Cerreto in the duchy of Spoleto, where his father was murdered in one of the frequent civil brawls which then disturbed the peace of Italian towns. His mother escaped with the boy to Perugia, and it was here that Pontano received his first instruction in languages and literature. Failing to recover his patrimony, he abandoned Umbria, and at the age of twenty-two established himself at Naples, which continued to be his chief place of residence during a long and prosperous career. He here began a close friendship with the distinguished scholar, Antonio Beccadelli, through whose influence he gained admission to the royal chancery of Alphonso the Magnanimous. Alphonso discerned the singular gifts of the young scholar, and made him tutor to his sons. Pontano's connection with the Aragonese dynasty as political adviser, military secretary, and chancellor was henceforth a close one; and the most doubtful passage in his diplomatic career is when he welcomed Charles VIII. of France upon the entry of that king into Naples in 1495, thus showing that he was too ready to abandon the princes upon whose generosity his fortunes had been raised. Pontano illustrates in a marked manner the position of power to which men of letters and learning had arrived in Italy. He entered Naples as a penniless scholar. He was almost immediately made the companion and trusted friend of its sovereign, loaded with honors, lodged in a fine house, enrolled among the nobles of the realm, enriched, and placed at the very height of social importance. Following the example of Pomponio Leto in Rome and of Cosimo de' Medici at Florence, Pontano founded an academy for the meetings of learned and distinguished men. This became the centre of fashion as well as of erudition in the southern capital, and subsisted long after its founder's death. In 1461 he married his first wife, Adriana Sassone, who bore him one son and three daughters before her death in 1491. Nothing distinguished Pontano more than the strength of his

domestic feeling. He was passionately attached to his wife and children; and, while his friend Beccadelli signed the licentious verses of *Hermaphroditus*, his own Muse celebrated in liberal but loyal strains the pleasures of conjugal affection, the charm of infancy, and the sorrows of a husband and a father in the loss of those he loved. Not long after the death of his first wife Pontano took in second marriage a beautiful girl of Ferrara, who is only known to us under the name of Stella. Although he was at least sixty-five years of age at this period, his poetic faculty displayed itself with more than usual warmth and lustre in the glowing series of elegies, styled *Eridanus*, which he poured forth to commemorate the rapture of this union. Stella's one child, Lucilio, survived his birth but fifty days; nor did his mother long remain to comfort the scholar's old age. Pontano had already lost his only son by the first marriage; therefore his declining years were solitary. He died in 1503 at Naples, where a remarkable group of terra cotta figures, life-sized and painted, still adorns his tomb in the church of Monte Oliveto. He is there represented together with his patron Alphonso and his friend Sanazzaro in adoration before the dead Christ.

As a diplomatist and state official Pontano played a part of some importance in the affairs of southern Italy and in the Baron's War, the wars with Rome, and the expulsion and restoration of the Aragonese dynasty. But his chief claim upon the attention of posterity is as a scholar. His writings divide themselves into dissertations upon such topics as the "Liberality of Princes" or "Ferocity," composed in the rhetorical style of the day, and poems. He was distinguished for energy of Latin style, for vigorous intellectual powers, and for the faculty, rare among his contemporaries, of expressing the facts of modern life, the actualities of personal emotion, in language sufficiently classical yet always characteristic of the man. His prose treatises are more useful to students of manners than the similar lucubrations of Poggio. Yet it was principally as a Latin poet that he exhibited his full strength. An ambitious didactic composition in hexameters, entitled *Urania*, embodying the astronomical science of the age, and adorning this high theme with brilliant mythological episodes, won the admiration of Italy. It still remains a monument of fertile invention, exuberant facility, and energetic handling of material. Not less excellent is the didactic poem on orange trees, *De Hortis Hesperidum*. His most original compositions in verse, however, are elegiac and hendecasyllabic pieces on personal topics—the *De Coniugali Amore*, *Eridanus*, *Tumuli*, *Nemise*, *Baise*, etc.—in which he uttered his vehemently passionate emotions with a warmth of southern coloring, an evident sincerity, and a truth of painting from reality which make the reader pardon an erotic freedom that is alien to our present taste. These lyrical compositions breathe the atmosphere of Naples, reproduce its scenery with wonderful brilliancy, and introduce us to the customs of its pleasure-loving pagan people. Yet, in spite of their excessive voluptuousness, we rise from their perusal convinced that their author was essentially a good man, a loving husband and father, and an attached friend.

Pontano's prose and poems were printed by the Aldi at Venice. For his life see Ardito, *Giovanni Pontano e i suoi Tempi*, Naples, 1871; for his place in the history of literature, Symonds, *Renaissance in Italy*. (J. A. S.)

PONTECORVO, a city of Italy in the province of Caserta, on the left bank of the Garigliano, with a population of 5172 in 1881 (commune 10,191), answers to the ancient Fregellæ, a Volscian city, colonized in 323 B.C. by the Romans, who thus occasioned the Second Samnite War. The principality of Pontecorvo (about 40 square miles in extent), which Napoleon bestowed on Bernadotte in 1806, was in 1810 incorporated with the French empire.

PONTEFRACT, or **POMFRET**, a market town and municipal and parliamentary borough in the West Riding of Yorkshire, England, finely situated on an eminence near the junction of the Calder and Aire, and on three railway lines, 13 miles southeast of Leeds, and 14 northwest of Doncaster. The streets are wide and regular, and there are many good houses and shops. A park over 300 acres in extent is used as a public recreation ground. The most important of the

antiquarian remains are the ruins of the famous castle situated on a rocky height, originally covering with its precincts an area of over 8 acres, and containing in all eight round towers. The principal feature remaining is the keep. The castle is said to occupy the site of a fortress erected by Ailric, a Saxon thane. It was founded by Ilbert de Lacy shortly after the Conquest, and probably nearly completed by Ilbert de Lacy the Second, who died about 1141. From that time to its demolition in 1649 it was the great stronghold of South Yorkshire. It was the cradle of the dukes of Lancaster, and in it Richard II. was, after his deposition, "kept secretly" till his death. Many persons of rank and influence have been confined in it as political prisoners. During the wars of York and Lancaster it was a centre of intrigue and conspiracy. In 1536 it surrendered to Aske, the leader of the "pilgrimage of grace." At the beginning of the Civil War it was garrisoned for Charles, and it underwent four sieges, three of them by the Parliamentary forces, and one by the Royalists. After its capitulation to Lambert in March, 1649, it was dismantled. Below the castle is All Saints church, which suffered severely during the siege of the castle, but still retains some work of the 12th century. In 1837 the tower and transepts were fitted up for divine service. The church of St. Giles, formerly a chapel of ease to All Saints, but made parochial in the 18th century, is of Norman date, but most of the present structure is modern. The 17th-century spire was removed in 1707, and replaced by a square tower, which was rebuilt in 1797; the chancel was rebuilt in 1869. In Southgate is an ancient hermitage and oratory cut out of the solid rock, which dates from 1396. On St. Thomas's Hill, where Thomas, earl of Lancaster, was beheaded in 1322, a chantry was erected in 1373, the site of which is now occupied by a windmill built of its stones. At Monkhill there are the remains of a Tudor building called the Old Hall, probably constructed out of the old priory of St. John's. A grammar school of ancient foundation, renewed by Queen Elizabeth and by George III., is now in abeyance. The town-hall was built in 1796 on the site of one erected in 1656, which succeeded the old moot-hall, dating from Saxon times. Among other buildings are the court-house, the market-hall, the assembly rooms (a handsome building adjoining the town-hall), and the dispensary. The principal alms-house, that of St. Nicholas, dates from Saxon times. Trinity Hospital was founded in the 14th century by the celebrated Sir Robert Knolles. There are extensive gardens and nurseries in the neighborhood, and liquorice is largely grown for the manufacture of the celebrated Pomfret cakes. The town possesses iron foundries, sack and matting manufactories, tanneries, breweries, corn mills, and brick and terra-cotta works. The population of the municipal borough (extended in 1875) in 1871 was 6432, and in 1881 it was 8798, the population of the parliamentary borough (area 7316 acres) in the same years being 11,563 and 15,322. The increase is mainly due to the fact that Pontefract is now a military centre.

There are indications that the Romans were stationed near the present town, which adjoins the Ermine Street. In Domesday it is called Tateshale, and is said previously to have been held by the king (Edward the Confessor). It then possessed a church and priest, one fishery, and three mills. Subsequently it is mentioned as Kirkby. Of the cause of the change of the name to Pontefract various unsatisfactory explanations are given. According to one account it was because when William advanced to the conquest of the north his passage was delayed by a broken bridge (but this was at Ferrybridge, 3 miles off); according to a second the name was bestowed on it by its Norman possessor from Pontfrette in Normandy (which, however, never existed); and according to a third the name perpetuates the remarkable preservation from drowning of those who fell into the river when the concourse of people made the bridge give way on the arrival of St. William of Canterbury in 1153 (although all contemporary historians call the

place Pontefract when Archbishop Thurstan died there in 1140). The town received a charter from Roger de Lacy in 1194, and was incorporated in the time of Richard III. As early as 1297 it returned two members to parliament; but there was a long discontinuance in the 14th, 15th, and 16th centuries. The practice was revived under James I. The "redistribution" measure of 1885 deprives it of one of its members. The municipal borough is divided into three wards, and is governed by six aldermen and eighteen councillors.

PONTEVEDRA, a maritime province of Spain, is bounded on the N. by Coruña, on the E. by Lugo and Orense, on the S. by Portugal (Entre Douro e Minho), and on the W. by the Atlantic, and has an area of 1739 square miles. The general character of the province is hilly, with a deeply indented coast; its products are those common to all GALICIA (*q.v.*), of which historical province it formed a part. The population in 1877 was 451,946, the municipalities with a population over 10,000 being La Estrada (23,528), Lalín (16,217), Lavadores (13,658), PONTEVEDRA (noticed below), Puenteareas (14,566), Redondela (10,073), Silveda (13,346), Tomiño (11,150), Tuy (11,710), and Vigo (13,416). Vigo is connected by rail with Tuy and Orense, and the line from Santiago to Vigo is open as far as to Carril.

PONTEVEDRA, capital of the above province, and an episcopal see, is a picturesque old granite-built town, pleasantly situated at the head of the Ria de Pontevredra, where the Lerez is spanned by the old Roman bridge (whence the name—*pons vetus*). The inhabitants engage in agriculture, sardine fishing, and the manufacture of cloth and hats. The population of the municipality in 1877 was 19,857.

PONTIANAK. See BORNEO.

PONTIFEX. The principal college of priests in ancient Rome consisted of the *pontifices*, the *rex sacrorum*, and the *flamines*, under the headship of the *pontifex maximus*. The *rex sacrorum* was the functionary who under the republic succeeded to the sacrificial duties which in old time had been performed by the king; the *flamines* were sacrificial priests of particular gods, the most important being the *flamen Diablis*, or priest of Jupiter, whose wife, the *flaminica Diablis*, was priestess of Juno. The *pontifices* on the other hand were not assigned to the service of particular gods, but performed general functions of the state religion; and their head, the *pontifex maximus*, was the highest religious authority in the state. For, while the *rex sacrorum* succeeded to the liturgical functions of the king, it was the *pontifex maximus* who inherited the substance of power in sacred things; the other members of the college were his counsellors and helpers, but no more. It is probable that there was no supreme pontifex under the kings, but that in accordance with the general rule that sacred officers went in threes, following the number of the old tribes, the king sat as sixth and chief among the five pontifices whom Numa is said to have instituted. The functions of *pontifex maximus* were indeed too weighty to be discharged by a subject in a monarchical government, and from Augustus to Gratian (382 A.D.) this supreme priesthood was held by the emperors in person. The original idea of the pontificate is as obscure as the name; it is by no means certain that *pontifex* means bridge-maker (as the commonest etymology has it) with reference to the duty of maintenance of the sacred Sublucian bridge, for there were *pontifices* from of old in other parts of Italy. Marquardt conjectures that the name originally denoted atoning functions, from the same root as appears in *purus*, *pœna*. In historical times the *pontifices* had a very extended sphere of duties, and claimed to possess professional "knowledge of things human and divine." The supreme pontiff was in the religion of the state what the father was in the religion of the family. His dwelling was in the *regia* close to the altar of Vesta, the sacred hearth of the state; and the most sacred objects of national worship, the *penates publici* and the mysterious palla-

dia of Roman sovereignty, were his special care. The *flamines* and *vestal virgins* were appointed by him and stood under his paternal power, and the stated service of their cults, as well as those exercises of public religion for which no special priests were provided, were under his charge or that of the college in which he presided. The *pontiffs*, moreover, supplied technical guidance and help in those religious functions in which the senate or magistrates had the first part; while the charge of the calendar with its complicated intercalation and system of feast days gave them an important influence on affairs of civil life. The control of the calendar is closely connected with the duties pertaining to the pontifical archives, which, besides a mass of ritual directions and the like, embraced the calendars of past years (including the *fasti consulares*) and the *Annales maximi* or annual chronicle of public events. Further the pontiffs had the weighty function of declaring and interpreting the laws of religion, which involved such important social matters as marriage and testamentary dispositions; but this function was declaratory and not magisterial; the state gave no executive power to the pontiffs, save only that the *pontifex maximus* exercised disciplinary authority over those priestly persons who stood under his paternal power. The pontiffs, who held office for life, originally filled up the vacancies in their number by cooptation, but as early as 212 B.C. the head of their college was named by the voice of the people, and in 104 B.C. the choice of the members of the priestly colleges was also transferred to *comitia* of a peculiar constitution. The number of *pontifices* was gradually enlarged, first to nine, and then, under Sulla, to fifteen, and the emperors exercised the right of adding supernumeraries at will.

PONTINE MARSHES. See LATIUM, vol. xiv. p. 343.

PONTOISE, a commercial town of France, at the head of an arrondissement of the department Seine-et-Oise, 18 miles by rail northwest of Paris, picturesquely situated on the right bank of the Oise where it is joined by the Viosne, and at the intersection of the railway from Paris to Dieppe by Gisors with that of the valley of the Oise. The traffic on the main river is large, and the tributary drives numerous mills. Of the many convents and churches that used to exist in the town two only remain: St. Maclou, a church of the 12th century, was altered and restored in the 15th and 16th centuries by Pierre Lemercier, the famous architect of St. Eustache at Paris; and Notre Dame, of the close of the 16th century, contains the tomb of St. Gautier (13th century). Grain and flour are the principal staples of the trade of Pontoise; the population in 1881 was 6675.

Pontoise existed in the time of the Gauls as Briva Isaræ (*i.e.*, Bridge of the Oise). The Romans made it the seat of forges dedicated to Vulcan, and thus the district came to be distinguished as Pagus Vulcanius or the Vexin. Pontoise was destroyed by the Normans in the 9th century, united with Normandy in 1032, and acquired by Philip I. in 1064. Lying on the borders of the two states it often passed from one to the other. The English took it in 1419, and again in 1436. In 1441 Charles VII. took it by storm after a three months' siege. After belonging to the count of Charolais down to the treaty of Conflans, it was given as a dowry to Jeanne of France when she was divorced by Louis XII. The parlement of Paris several times met in the town; and in 1561 the states-general convoked at Orleans removed thither after the death of Francis II. During the Fronde it offered a refuge to Louis XIV. and Mazarin. Henry III. made it an apanage for his brother the duke of Anjou. At a later period it passed to the duke of Conti. Down to the Revolution it remained a monastic town. Philip the Bold, founder of the house of Burgundy, the architects Pierre and Jacques Lemercier, and Tronson-Ducoudray, one of the defenders of Marie Antoinette, are among the natives of Pontoise.

PONTON. Pontons are vessels employed to support the roadway of floating bridges. They may be either open or closed, heavy and only movable when

floated, or light enough to be taken out of the water and transported overland, as when required to form part of the equipment of an army in the field.

From time immemorial floating bridges of vessels bearing a roadway of beams and planks have been employed to facilitate the passage of rivers and arms of the sea. Xerxes crossed the Hellespont on a double bridge, one line supported on three hundred and sixty, the other on three hundred and fourteen vessels, anchored head and stern with their keels in the direction of the current. Darius threw similar bridges across the Bosphorus and the Danube in his war against the Scythians, and the Greeks employed a bridge of boats to cross the river Tigris in their retreat from Persia. Floating bridges have been repeatedly constructed over rivers in Europe and Asia, not merely temporarily for the passage of an army, but permanently for the requirements of the country; and to this day many of the great rivers in India are crossed, on the lines of the principal roads, by floating bridges, which are for the most part supported on boats such as are employed for ordinary traffic on the river.

But light vessels which can be taken out of the water and lifted on to carriages are required for transport with an army in the field. Alexander the Great occasionally carried with his army vessels divided into portions, which were put together on reaching the banks of a river, as in crossing the Hydaspes; he is even said to have carried his army over the Oxus by means of rafts made of the hide tents of the soldiers stuffed with straw, when he found that all the river boats had been burnt. Cyrus crossed the Euphrates on stuffed skins. In the 4th century the emperor Julian crossed the Tigris, Euphrates, and other rivers by bridges of boats made of skins stretched over osier frames. In the 17th century the Germans employed timber frames covered with leather as pontoons, and the Dutch similar frames covered with tin; and the practice of carrying about skins to be inflated and employed for the passage of troops across a river, which was adopted by both Greeks and Romans, still exists in the East, and has been introduced into America in a modified form, india-rubber being substituted for skins.

Pontoons have been made of a variety of forms and of almost every conceivable description of material available for the purpose of combining the two essential qualities of transportability over land and power of support in water. As these qualities are not only distinct but conflicting, one of them has been frequently sacrificed to the other. Thus history records many instances of bridges having failed because incapable of supporting all the weight they were called on to bear, or of resisting the force of the current opposed to them; it also records instances of important strategic operations being frustrated because the bridge equipment could not be brought up in time to the spot where it was wanted. Numerous expedients for lightening the equipment have been suggested, in America more particularly; but the proposers have not always remembered that if a military bridge is intended to be carried *with* an army it is also intended to *carry* the army, with its columns of infantry and cavalry, its numerous wagons, and its ponderous artillery, and it ought to do so with certainty and safety, even though a demoralized rabble should rush upon it in throngs.

Pontoons have been made of two forms, open as an undecked boat, or closed as a decked canoe or cylinder. The advantage claimed for the closed pontoon is that it cannot be submerged by the river, but only by having to bear a greater load than its buoyancy admits of; the disadvantages are that it is difficult to make and keep water-tight, it requires special saddles for the support of the baulks which carry the roadway, and it cannot be conveniently used as a row-boat. During the Peninsular War the English employed open bateaus, as did and still do all the other European nations; but the experience gained in that war induced

the English to abandon the open bateau; for if large it was very difficult to transport across country, and if small it was only suited for tranquil streams, being liable to fill and sink should the river rise suddenly or become disturbed by the wind. Thus closed pontoons came to be introduced into the British army. General Colleton devised the first substitute for the open bateau, a buoy pontoon, cylindrical with conical ends and made of wooden staves like a cask. Then General Pasley introduced demi-pontoons, like decked canoes with pointed bows and square sterns, a pair, attached sternwise, forming a single "pier" of support for the roadway; they were constructed of high timber frames covered with sheet copper and were decked with wood; each demi-pontoon was divided internally into separate compartments by partitions which were made as water-tight as possible, and also supplied with the means of pumping out water; when transported overland with an army, a pair of demi-pontoons and the superstructure of one bay formed the load for a single carriage weighing 3110 lb when loaded. The Pasley was superseded by the Blanshard pontoon, a tin-coated cylinder with hemispherical ends, for which great mobility was claimed, two pontoons and two bays' superstructure being carried on one wagon, giving a weight of about 5000 lb, which was intended to be drawn by four horses. The Blanshard pontoon was long adopted for the British army, but it is now being discarded; experiments made with it in peace time showed that it would probably break down under the strain of actual warfare, and efforts were constantly made to improve on it; when immersed to a greater depth than the semi-diameter it became very unstable and lively under a passing load, a defect which Serjeant-Major Forbes proposed to remedy by giving it a triangular instead of a circular section, thus increasing the stability by presenting a continually increasing area of bearing surface up to the level of total immersion; but the angles of these pontoons were found so liable to injury as to counterbalance any advantages over the cylinders. After many years' experience of the closed pontoon the English engineers came to the conclusion that it was desirable to return to the form of the open bateau to which the engineers of all the Continental armies had meanwhile constantly adhered. Captain Fowke, R. E., invented a folding open bateau, made of water-proof canvas attached to sliding ribs, so that for transport it can be collapsed like the bellows of an accordion and for use it can be extended by a pair of stretchers; it is very mobile, but it is also deficient in power of support, for whereas the buoyancy due to the outline form out of the water is 13,600 lb the actual buoyancy in the water is only 8640 lb, because of the cavities in the canvas between the ribs which are formed by the pressure of the water outside; moreover, the surface irregularities cause the pressure exerted by a current upon a bridge formed of these collapsible pontoons to be about three times as much as upon one of equal power formed with Blanshard's or Pasley's pontoons; there is thus great risk of the bridge being carried away by a strong current.

The following table shows the powers of various pontoons at present or recently in use by different nations. The "working power of support" has been calculated in most instances by deducting from the "available buoyancy" one-fourth for open and one-tenth for closed vessels:

In the English and French equipment the pontoons were originally made of two sizes, the smaller and lighter for the "advanced guard," the larger and heavier for the "reserve"; in both equipments the same size pontoon is now adopted for general requirements, the superstructure being strengthened when necessary for very heavy weights. The Austrian and Italian pontoons are made in three pieces, two with bows and a middle piece without; not less than two pieces are ordinarily employed, and the third is introduced when great supporting power is required, but in all cases a constant interval is maintained between the pontoons. On the other hand in the Prussian, Russian, Dutch, and American and in the English Blanshard equipments greater sup-

¹ [Francis (1823-65), architect of South Kensington Museum, and of other art and science institutions.—AM. ED.]

generally employed even in America, where it was invented. The engineer officers with the army of the Potomac, after full experience of the india-rubber pontoon and countless other inventions of American genius, adopted the French equipment, which they found "most excellent, useful, and reliable for all military purposes." The Russians in crossing the Danube in their war with Turkey in 1878 employed the Austrian equipment.

PONTOPPIDAN, ERIK (1698–1764), a learned Danish author, was born at Aarhus on August 24, 1698, and studied divinity at the university of Copenhagen. On finishing his education he was appointed travelling tutor to several young noblemen in succession, and in 1735 he became one of the chaplains of the king. In 1738 he was made professor extraordinarius of theology at Copenhagen, and in 1747 bishop of Bergen, Norway, where he died on December 20, 1764.

His principal works are—*Theatrum Danicæ veteris et modernæ* (4to, 1730), a description of the geography, natural history, antiquities, etc., of Denmark; *Gesta et Vestigia Danorum extra Daniam* (2 vols. 8vo, 1740), of which laborious work it is enough to remark that it was written before the rise of the modern historical school; *Annales Ecclesiæ Danicæ* (4 vols. 4to); *Marmora Danica Selectiora* (2 vols. fol., 1739–41); *Glossarium Norvegicum* (1749); *Det første Forsøg paa Norges naturlige Historie* (4to, 1752–54; Eng. trans., *Natural History of Norway*, 1755), containing curious accounts, often referred to, of the Kraaken, sea-serpent, and the like; *Origines Hafnienses* (1760). His *Danske Atlas* (7 vols. 4to) was mostly posthumous.

PONTORMO, JACOPO DA (1494–1557), whose family name was CARUCCI, a painter of the Florentine school, was born at Pontormo in 1494, son of a painter of ordinary ability, was apprenticed to Leonardo da Vinci, and afterwards took lessons from Pier di Cosimo. At the age of eighteen he became a journeyman to Andrea del Sarto, and was remarked as a young man of exceptional accomplishment and promise. Later on, but still in early youth, he executed, in continuation of Andrea's labors, the Visitation, in the cloister of the Servi in Florence—one of the principal surviving evidences of his powers. The most extensive series of works which he ever undertook was a set of frescos in the church of S. Lorenzo, Florence, from the Creation of Man to the Deluge, closing with the Last Judgment. By this time, towards 1546, he had fallen under the dangerous spell of Michelangelo's colossal genius and superhuman style; and Pontormo, after working on at the frescos for eleven years, left them incomplete, and the object of general disappointment and disparagement. They were finished by his leading pupil Angelo Bronzino, but have long since vanished under whitewash. Among the best works of Pontormo are his portraits, which include the likenesses of various members of the Medici family; they are vigorous, animated, and highly finished. He was fond of new and odd experiments both in style of art and in method of painting. From Da Vinci he caught one of the marked physiognomic traits of his visages, smiles, and dimples. At one time he took to direct imitation or reproduction of Albert Dürer, and executed a series of paintings founded on the Passion subjects of the German master, not only in composition, but even in such peculiarities as the treatment of draperies, etc. Italian critics, both contemporary and of later date, have naturally regarded this as a very perverse aberration. Pontormo died of dyspepsy on 2d January, 1557, mortified at the ill success of his frescos in S. Lorenzo; he was buried below his work in the Servi. He was a man of solitary self-neglectful habits, a slow worker, receiving comparatively little aid from scholars, indifferent to gain or distinguished patronage, and haunted by an instinctive horror of death.

PONTUS was the name given in ancient times to an extensive tract of country in the northeast of Asia Minor, bordering on Armenia and Colchis (see vol. xv. Plate II.). It was not, like most of the divisions of Asia, a national appellation, but a purely territorial one, derived from its proximity to the Euxine, often called simply Pontus by the Greeks. Originally it formed part of the extensive region of Cappadocia, which in early ages extended from the borders of Cilicia to the Euxine; but afterwards it came to be divided into two satrapies or governments, of which the northernmost came to be distinguished as "Cappadocia on the Pontus," and thence simply as "Pontus." The term is not, however, found either in Herodotus or Xenophon, though the latter traversed a considerable part of the region, and it is probable that it did not come into general use until after the time of Alexander the Great. Under the Persian empire the province continued to be governed by a satrap, nominally subject to the great king, but apparently enjoying virtual independence, as no mention occurs in Xenophon of the Persian authorities in this part of Asia. The first of these local satraps who assumed the title of king was Ariobarzanes, about the beginning of the 4th century B.C., who was reckoned the founder of the dynasty; but its history as an independent monarchy really begins with Mithradates II., who commenced his reign in 337 B.C. From this time Pontus continued to be ruled by a succession of kings of the same dynasty, mostly bearing the name of Mithradates, whose independence was respected by the Macedonian sovereigns of Asia, and who were able gradually to extend their power along the shores of the Euxine. The capture of the important city of Sinope by Pharnaces I. (about 183 B.C.) led to the extension of their frontier to that of Bithynia; while under Mithradates VI., commonly known as the Great, their dominion for a time comprised a large part of Asia Minor. The history of the reign of that monarch and his wars with the Romans will be found under the heading MITHRADATES. After his final defeat by Pompey in 65 B.C., Pontus was again confined within its original limits, but was united with Bithynia as a Roman province, and this union generally continued to subsist, though not without interruption, under the Roman empire. A portion of the original dominion of the kings of Pontus was, however, separated from the rest by Antony in 36 B.C., and placed under the government of a Greek rhetorician named Polemon, whose descendants continued to rule it till the reign of Nero, when it was finally annexed to the Roman empire (63 A.D.). Hence this part of the country came to be known as Pontus Polemoniacus, by which epithet it was still distinguished as a Roman province. The interior district in the southwest, adjoining Galatia, hence came to be known as Pontus Galaticus.

Pontus, in the proper sense of the term, as defined by Strabo, who was himself a native of the country, was bounded by the river Halys on the west, and by Colchis and the Lesser Armenia on the east. Its exact frontier in this direction is not specified, but it may be taken as extending as far as the mouth of the river Acampsis. The region thus limited may be considered as divided into two portions, differing much in their physical characters. The western half presents considerable plains and upland tracts in the interior, stretching away till they join the still more extensive uplands of Cappadocia and Galatia. Besides the great river Halys that forms its boundary on the west, this region is traversed by the river Iris, and its tributary the Lycus, both of which have their rise in the highlands on the frontiers of Armenia, and are very considerable streams, flowing through fertile valleys. The Thermodon, which enters the Euxine a little to the east of the Iris, is a much less important stream, though celebrated from its connection with the fable of the Amazons. On the other hand the eastern por-

tion of Pontus, between Armenia and the Euxine, is throughout a very rugged and mountainous country, furrowed by deep valleys descending from the inland range of mountains, known to the ancients as Paryadres, which has a direction nearly parallel to the sea-coast, and is continued to the frontiers of Colchis under the name of Seydises and various other appellations. These mountains have in all ages been almost inaccessible, and even in the time of Strabo were inhabited by wild tribes who had never been really reduced to subjection by any government. But the coast from Trebizond westward is one of the most beautiful parts of Asia Minor, and is justly extolled by Strabo for its wonderful productiveness in fruits of every description.

The population of the greater part of Pontus was undoubtedly of the same race with that of Cappadocia, of which it originally formed a part, and was therefore clearly of Semitic origin.¹ Both nations were frequently comprised by the Greeks under the term *Leucosyri* or White Syrians. But the rugged mountain districts in the northeast, towards the frontiers of Colchis and Armenia, were occupied by a number of semi-barbarous tribes, of whose ethnical relations we are wholly ignorant. Such were the Chaldæans or Chalybes (identified by the Greeks with the people of that name mentioned by Homer), the Tibareni, the Mosynœci and the Macrones. Some light is thrown on the manners and condition of these people by Xenophon, who traversed their country on his march from Trapezus to Cotyora (*Anab.*, v.) but we have otherwise hardly any information concerning them.

The sea coast of Pontus, like the rest of the south shore of the Euxine, was from an early period studded with Greek colonies, most of them of Milesian origin, though in many cases deriving their settlement directly from Sinope, itself a colony of Miletus. Next to that city, between the mouth of the Halys and that of the Iris, stood Amisus, originally a colony direct from Miletus, but which subsequently received a body of Athenian settlers. It was one of the most flourishing of the Greek colonies on this coast, and is still a considerable town under the name of Samsun. Proceeding eastward from thence, we find Side, called in later times Polemonium; Cotyora, a colony of Sinope, where Xenophon embarked with the ten thousand Greeks; Cerasus, afterwards named Pharnacia; and Trapezus, also a colony of Sinope, which was a flourishing and important town in the days of Xenophon, but did not attain till a later period to the paramount position which it occupied under the Roman and Byzantine empire, and which it still retains under the name of TREBIZOND (*q.v.*).

But, besides these Greek settlements, there were in the interior of Pontus several cities of considerable importance, which were of native origin, though they had gradually received a certain amount of Greek culture. The principal of these were Amasia, on the river Iris, the birth-place of Strabo, which was made the capital of his kingdom by Mithradates the Great, but had previously been the burial-place of the earlier kings, whose tombs are still extant, and have been described by Hamilton and other travellers; Comana, higher up the valley of the same river, which, like the place of the same name in Cappadocia, was consecrated to a native goddess named Ma, identified by Strabo with the Greek Enyo, and derived great celebrity from its sacred character, having a large fixed population under the direct government of the priests, besides being the resort of thousands of pilgrims; Zela, nearer the frontier of Galatia, which was in like manner consecrated to a goddess named Anaitis; and Cabira, in the valley of the Lycus, afterwards called Neocæsarea, a name still retained in the abbreviated form of

the modern Niksar. Several smaller towns are mentioned by Strabo as giving name to the surrounding districts, of which he has left us the names of not less than fifteen; but these obscure appellations of local divisions are in themselves of little interest, and for the most part not mentioned by any other writer.

(E. H. B.)

PONTUS DE TYARD (c. 1521–1605), one of the famous Pleiade who helped to reform French literature in the 16th century, was the highest in rank and the most affluent in fortune of the seven. He was indeed in some sort an anticipator of Ronsard and Du Bellay, for his *Erreurs Amoureuses* preceded their work. He was seigneur of Bissy in Burgundy, was born at the seignorial house in or about 1521, and died at a great age at Bragny on the Saône, another seat of his, on September 25, 1605. He was thus the last survivor as well as one of the eldest of the group. His early poems, the *Erreurs Amoureuses*, originally published in 1549, were augmented with other works in successive editions till 1573. Pontus de Tyard published *Discours Philosophiques* in 1587, and appears to have been a man of extensive knowledge and just thought. He was, moreover, a courtier and official of some standing for many years, and, entering the church, was made count-bishop of Châlons-sur-Saône. In this high position he bore a character for political and religious moderation. On the whole his poetry is inferior to that of his companions, but he was one of the first to write sonnets in French (the actual priority belongs to Mellin de St. Gelais); and one of these, the beautiful Sonnet to Sleep (it has been noted that the poetical name of his mistress in the *Erreurs* is, oddly enough, Pasithea, the name of the nymph beloved classically by the god of sleep), is a very notable and famous piece. It is also said that Pontus de Tyard introduced the sestet into France, or rather reintroduced it, for it is originally a Provençal invention.

PONTYPOOL, a town and urban sanitary district of Monmouthshire, England, situated on an acclivity above the river Avon Lwyd, on the Monmouthshire Canal, and on the Great Western and Monmouthshire Railways, 8 miles north of Newport. The town-hall, in the Doric style, dates from 1856, the market-house from 1846, and the Baptist theological college from 1856. At one period Pontypool was famed for its japanned goods, invented by Thomas Allwood, a native of Northampton, who settled in the town in the reign of Charles II., but the manufacture has long been transferred altogether to other towns. The present prosperity of Pontypool is due to its situation on the edge of the great Pembrokeshire coal and iron basin. The earliest record of trade in iron is in 1588, but it was developed chiefly in the beginning of the 18th century by the Hanburys, the proprietors of Pontypool Park. The town possesses large forges and iron-mills for the manufacture of iron-work and tinplate. The population of the urban sanitary district (area 800 acres) in 1871 was 4834, and in 1881 it was 5244.

PONTYPRIDD, sometimes also called NEWBRIDGE, a market town of Glamorganshire, Wales, situated on the Taff at its junction with the Rhondda, and on the Glamorganshire Canal, 12 miles north-northwest from Cardiff and 12 south from Merthyr-Tydfil. It receives its name from a remarkable bridge of one arch spanning the Taff, erected by William Edwards, a self-taught mason. The bridge is a perfect segment of a circle, the chord being 140 feet, and the height at low water 36 feet. A three-arched bridge was erected close to it in 1857. The principal buildings are the court-house, St. Catherine's church, the masonic hall, and the town-hall. Near the town is a far-famed rocking stone 9½ tons in weight, surrounded by so-called Druidical remains. In the beginning of the century Pontypridd was an insignificant village, and it owes its progress chiefly to the coal and iron in the neighborhood. It possesses anchor, chain, and

¹ Such at least was the general opinion of Greek writers. The Semitic or Aramæan origin of the Cappadocians has, however, in modern times been questioned by Nöldeke and other authorities on Semitic ethnology.

able works, chemical works, and iron and brass foundries. The population in 1881 was 12,317.

PONZA, the principal island of a small volcanic group, the Pontian, Pontine, or Pontinian Islands (*Insule Pontie, Isole Ponze*), which lie 20 miles off the Circeian promontory (Monte Circello), the northern end of the Gulf of Gaeta, on the west coast of Italy. The two smaller islands are Palmarola (ancient *Palmaria*) and Zannone (*Simonia*), neither inhabited. Ponza is 5 miles long and very irregular in outline; its soil is fertile; and in 1881 it had 3828 inhabitants. The old fortress is used as a penal establishment.

A Roman colony with Latin rights was settled on Pontia in 313 B.C. Under the empire the island was a place of banishment for political offenders. Nero, the eldest son of Germanicus, here perished by command of Tiberius; here the sisters of Caligula were confined; and here, or in Palmaria, Pope Sylvester died. A Benedictine monastery was built on Ponza, and in 1572 Cardinal Farnese, as commendatory of the monastery, claimed to exercise lordship over the island. From the duke of Parma, who obtained possession in 1588, the feudal authority passed with Elizabeth to Philip V. of Spain. Ferdinand IV. attracted the inhabitants of Torre del Greco to the island by gifts of land and money. During the first French empire it was occupied and fortified by the English and Sicilian forces.

See Tricoli, *Monografia per le isole del gruppo Pontiano*, Naples, 1855; Mattei, *L'Archipelago Pontiano*, Naples, 1857; and Doelter, *Vorläufige Mittheilung über den geol. Bau der Pontinischen Inseln*, Vienna, 1875.

POOLE, a market town, municipal borough, county in itself, and seaport of Dorsetshire, on the south coast of England, is picturesquely situated on a peninsula between Holes Bay and Poole Harbor, 30 miles east from Dorchester and 120 southwest of London. The churches are modern, and possess no features of special interest. Among the principal public buildings are the town-house, 1721; the guild-hall, formerly the market-house, 1761; the old town-hall, built in 1572; the custom-house; and the mechanics' institute. On Brownsea Island in the middle of Poole Harbor is a small castle erected as a fortress by Elizabeth and strengthened by Charles I. At low water Poole Harbor is entirely emptied except a narrow channel, but at full tide the water covers an area about 7 miles long by about $4\frac{1}{2}$ broad. The quays lined with warehouses are about one mile in length, and can be approached by vessels of very large tonnage. There is a large general trade with the British colonies and the United States, and an important coasting trade, especially in corn to London, and Purbeck clay to the Staffordshire potteries. In 1883 the number of vessels that entered the harbor was 933 of 81,003 tons, the number that cleared 874 of 77,948 tons. Some shipbuilding is carried on, and there are manufactures of cordage, netting, and sailcloth. The town also possesses large potteries, decorative tile works, iron-foundries, engineering works, agricultural implement works, and flour-mills. The area of the borough is 5111 acres, with a population in 1871 of 10,129, and in 1881 of 12,310 (5820 males and 6490 females).

Poole derives its name from being nearly surrounded by a sheet of water. There was a Roman road between it and Winbourne. It is not mentioned in Domesday, being included in Canford, but it enjoyed certain immunities before 1248, when it received a charter from William Longsword. In the reign of Edward III. it supplied four ships and 94 men for the siege of Calais. Much of its succeeding prosperity was due to the presence of Spanish merchants, and after the outbreak of war with Spain in the reign of Elizabeth its trade for a time declined. Its charter was extended by Elizabeth, who reincorporated it, and erected it into a county in itself. It has a sheriff elected annually, and a separate court of quarter sessions. It is divided into two wards, and is governed by a mayor, six aldermen, and eighteen councillors. It returned two members to Parliament as early as the reign of Edward III., but one only from 1868 to 1885.

See Hutchins, *History of Poole*, 1788; Sydenham, *History of Poole*, 1839; Hutchins, *History of Dorset*, 3d ed.

POOLE, MATTHEW (1624-1679), author of a

learned though now almost wholly antiquated *Synopsis Criticorum Biblicorum*, was born at York in 1624, was educated at Emmanuel College, Cambridge, and from 1648 till the passing of the Act of Uniformity held the rectory of St. Mary le Querne, London. Subsequent troubles led to his withdrawal to Holland. He died at Amsterdam in 1679.

Besides the work with which his name is principally associated (*Synopsis Criticorum Biblicorum*, 5 vols. fol., 1660-76), he wrote *Annotations on the Holy Bible*, as far as to Isa. lviii.; the work was subsequently completed by several of his Nonconformist brethren, and published in 2 vols. fol. in 1683. He was also the author of numerous controversial tracts.

POOLE, PAUL FALCONER (1806-1879), an eminent English painter was born at Bristol in 1806. He was self-taught in the strictest sense, and to this deficiency in art training must be ascribed the imperfect drawing of the human figure which is to be observed in most of his work. But, in spite of this drawback, his fine feeling for color, his poetic sympathy, and his dramatic power have gained for him a high position among British artists. Gifted with an imagination of a high order he boldly attempted lofty historical themes, and, if the result is not always equal to the vigor of his conception, we can easily see that the shortcoming was due to his imperfect education in art. His pictures show him to belong to that comparatively small class of English painters who are keenly sensitive to the influence of beauty and of passion, rising on occasion to ambitious flights of fancy, and dominated by strong dramatic impulse. A keen observer of nature, but generally viewing it in a broad comprehensive aspect, he was truly a poet-painter, using the effects of a summer sky or of angry clouds to harmonize with the subject of his picture and to enforce its story. In his early days Poole worked along with T. Danby, and it is easy to trace the bond of sympathy between the two painters.

Poole's life was the simple uneventful record of the career of the artist. He exhibited his first work in the Royal Academy at the age of twenty-five, the subject being the Well—a scene in Naples. There was an interval of seven years before he again exhibited his Farewell, Farewell, in 1837, which was followed by the Emigrant's Departure, Hermann and Dorothea, and By the Waters of Babylon. This last picture attracted much attention from the fine poetic imagination which it displayed. In 1843 his position was made secure by his Solomon Eagle, and by his success in the Cartoon Exhibition, in which he received from the Fine Art Commissioners, a prize of £300 sterling [\$1,458]. After his exhibition of the Surrender of Syon House he was elected an Associate of the Royal Academy in 1846, and was made an Academician in 1861. In 1855 he received a medal of the third class at the Paris Universal Exhibition. His enthusiasm for his art was rewarded by success in life, though like many artists he passed through much hardship in his early days. He died in 1879, in his house at Hampstead, in his seventy-third year. In person he was tall and well built, with a lofty forehead, gray eyes, and short beard. The portrait sketch by Frank Holl, R. A., gives a very good idea of him in his last days—a shy man but genial to his friends, fond of conversation and well read, especially in his favorites Shakespeare, Shelley, Spencer, and Chaucer, who were the sources of inspiration of many of his works.

Poole's subjects easily divide themselves into two orders—one, without doubt the earlier, idyllic, the other dramatic. Of the former his May Day is a typical example. A rustic beauty crossing a brook, or resting on a hill side under bushes flecked with the light and shade of a bright sun and with cirrus clouds floating in a blue sky, is the frequent motive of these works, which are full of simple enjoyment of a beautiful country life. But in his later style he rises to loftier subjects and treats them powerfully. Of both styles there were excellent examples to be seen in the small collection of his works shown at Burlington House in the Winter Exhibition of 1883-84. These collected pictures

recalled the attention of the public to a painter who had suffered neglect for some years, alike from his own deficiencies as a draughtsman and also from a want of sympathy with the poetical character of his paintings, which never could have been popular with the ordinary public. His reputation will stand or fall by the criticism of this gathering of his pictures, small though it was. There was to be seen one of his early dramatic pictures, painted in 1843, Solomon Eagle exhorting the People to Repentance during the Plague of 1665, terrible in its ghastly force. Though exaggerated in the expression of horror and agony, weak in drawing, and defective in color, it is clearly the work of a powerful imagination. To this class belong also the Messenger announcing to Job the Irruption of the Sabaeans and the Slaughter of the Servants (exhibited in 1850), and Robert, Duke of Normandy and Arletta (1848). Finer examples of his more mature power in this direction are to be found in his *Prodigal Son*, painted in 1869; the *Escape of Glaucus and Ione* with the blind girl Nydia from Pompeii (1860); and *Constance sent adrift* by the Constable of Alla, King of Northumberland, painted in 1868. Here Poole rises to a lofty height, and succeeds fully in realizing the impression he aims at. The expression of anguish and of resignation as Constance clasps her child to her bosom and turns her moon-lit face to heaven is rendered with great power, while the effect is heightened by the stormy sky, the dark rocks, and the angry sea.

More peaceful than these are the *Song of Troubadours* (painted 1854) and the *Goths in Italy* (1851), the latter an important historical work of great power and beauty. It represents the easy luxurious insolence of the barbarian conquerors, lying stretched on the grass in the gardens of Lucullus and Cicero; while the captive daughters of proud senators wait on them and offer wine in golden goblets. In the background is a circular temple overhanging the sea, while overhead is a beautiful sky—altogether a bold feat to attempt, yet Poole has succeeded in giving a great representation of a striking page in history.

Of a less lofty strain, but still more beautiful in its workmanship, is the *Seventh Day of the Decameron*, painted in 1857. In this picture Poole rises to his full height as a colorist. "In the fore-ground is Philomena, seated on the shore of a lake surrounded by high mountains, playing on a harp; eleven figures are grouped round her in various positions," as described in the catalogue. The chief beauty of this work lies in its fine color and quiet repose. The amphitheatre of rocky mountains reflected in the lake gives us a splendid example of Poole's power in landscape, which is large and broad in style. His treatment corresponded with his choice of subject. In his pastorals he is soft and tender, as in the *Mountain Path* (1853), the *Water-Cress Gatherers* (1870), the *Shepton Maiden* (1872). But when he turns to the grander and more sublime views of nature his work is bold and vigorous. Fine examples of this style may be seen in the *Vision of Ezekiel* of the National Gallery, *Solitude* (1876), the *Entrance to the Cave of Mammon* (1875), the *Dragon's Cavern* (1877), and perhaps best of all in the *Lion in the Path* (1873), a great representation of mountain and cloud form. This wild rocky landscape had a great fascination for him; every aspect of nature which showed the action of mighty force attracted him; hence his love of mountain sides scarred by ravines, and of trees torn and twisted by hurricanes. Caverns are a frequent theme; indeed he used to say that he had been haunted all his life by them, and that he would travel far to see a new one.

POONA, a district in the Deccan, Bombay, situated between the 17° 54' and 19° 23' N. lat., and 73° 24' and 75° 13' E. long. It has an area of 5347 square miles, and is bounded on the N. by the districts of Nasik and Ahmednagar, on the E. by those of Ahmednagar and Sholapur, on the S. by the Nira river, separating it from Satara and Phaltan, and on the W. by the Bhor state and Sahyadri Hills. Towards the west the country is extremely undulating, and numerous spurs from the hills enter the district. To the east it opens out into plains; but a considerable area is now being put under forest. Poona is watered by many streams which, rising in the Sahyadri range, flow eastwards until they join the Bhima, a river which intersects the district from north to south. The Great Indian Peninsula Railway runs through it, and affords an outlet for its produce through the Bhor Ghat to Bombay; another railway is about to be commenced which will put the district into communication with the southern Mahratta country. The

Khadakvasla Canal, about 10 miles southwest of Poona, which it supplies with water, is one of its most important works. Although the district is not rich in minerals, trap rock suitable for road-making and stone for building purposes are found. Only in the west are wild animals met with, chiefly tigers, leopards, bears, and *sambhar* deer. The climate is dry and invigorating; the average annual rainfall is about 30 inches.

The population of the district in 1881 was 900,621, (455,101 males and 445,520 females), of whom 834,843 were Hindus, 42,036 Mohammedans, 1574 Parsis, 10,880 Jains, 9500 Christians, and 1788 of other religions. The only towns with a population exceeding 10,000 are POONA (*q. v.*) Poona cantonment (30,129, and Junnar (10,373).

Agriculture supports about half the population. Of a total area of Government culturable land of 1,924,630 acres, 1,775,583, were cultivated during 1882-83. Of these 181,395 acres were fallow land and occupied waste, leaving 1,594,188 acres under actual cultivation, of which 28,035 were twice cropped. The chief products are cereals (chiefly jowari and bajri) and pulse, and the principal manufactures of the district are silk robes, coarse cotton cloth, and blankets; its brass and silver work is much admired. The gross revenue in 1882-83 was £180,736, [\$578,376.96], of which the land tax yielded £111,740, [\$543,056.40] stamps £18,790, [\$91,319.40], and excise £31,160, [\$151,437.60].

History.—The district passed from the last Hindu dynasty which reigned at Deogiri to the Mohammedans between 1294 and 1312, and under the Bahmani kings the Ghat country was thoroughly subdued. On the disruption of the Bahmani kingdom after the revolt of the governors of the provinces, the district fell to the share of the Ahmednagar kings and from them it passed to the Moguls, when the Nizamshahi dynasty finally came to an end in 1637. The country north of the Bhima, including Junnar, was annexed to the Mogul territory, and that south of it was made over to Bijapur. The power of the latter was, however, declining, and gave an opportunity to the Mahratta chiefs to unite and assert themselves, and ended in their establishing a Mahratta kingdom at Satara. Intrigues at the palace led to the supremacy of the peshwas and the removal of the capital to Poona, where many stirring scenes in Mahratta history have been enacted. Holkar defeated the peshwa under its walls, and his flight to Bassein led to the treaty by which he put himself under British protection; he was reinstated in 1802, but, unable to maintain friendly relations, he attacked the British at Kirkee in 1817, and his kingdom passed from him.

POONA, the chief town of the above district, is situated in 18° 31' N. lat. and 73° 55' E. long., in a treeless plain about 2000 feet above the sea and overlooked by the Ghats, which rise 1000 feet above the plain. Its area is about 4 square miles, with a population in 1881 of 99,622—males 50,814, females 48,808. The town stands on the right bank of the Muta river, and is about 80 miles southeast of Bombay. Until the year 1817, when it was taken by the British, the city was the residence of the peshwas of the Mahrattas.

POOR LAWS. Without embarking on an inquiry as to the causes of pauperism or the primary right of any persons to have their wants, however pressing, met by the state, it is sufficient to say that in Great Britain "there is no man so indigent or wretched but he may demand a supply sufficient for all the necessities of life from the more opulent part of the community, by means of the several statutes enacted for the relief of the poor" (Blackstone). Moreover, apart from statute, by the common law of England the poor were sustainable "by parsons, rectors of the church, and the parishioners, so that none of them die for default of sustenance" (*Mirror*).

The great importance of the subject of relief of the poor is evinced, apart from other considerations, by the number of persons immediately affected, either as recipients of relief or as ratepayers, and by the sums expended in that relief. The number of paupers of all classes now in receipt of relief in England and Wales approaches 800,000, equivalent to a thirty-fourth part of the entire population and relieved at a yearly cost of considerably more than £8,000,000, representing a charge of between six and seven shillings per head of the estimated population.

Of existing legislation a statute of the beginning of the 17th century (43 Eliz. c. 2, 1601) is the earliest, under which, by parochial taxation, parish officers are directed to provide a stock of materials for "setting the poor on work" (that is to say, persons "married or unmarried having no means to maintain them [and that] use no ordinary and daily trade of life to get their living by"), and further for setting to work their children; "and also competent sums of money for and towards the necessary relief of the lame, impotent, old, blind, and such others among them being poor and not able to work." The same statute enacts "that the father and grandfather and the mother and grandmother and the children of every poor old, blind, lame, and impotent person, or other poor person not able to work, being of a sufficient ability, shall at their own charges relieve and maintain every such poor person."

Although the statute of Elizabeth is spoken of as the principal foundation of existing legislation relating to the poor, it is an error to say that the relief of the poor originated at that period. The common law of England has been already cited, and traces of poor laws, however far removed from a system, are found in all civilized states. An approximation to the principle may be discerned in the legislation of England at a very early period; and before the Norman Conquest laws of Athelstane, establishing a responsibility over households and landowners, although intended for good order and calculated to prevent the growth of vagabondage and violence, had also the effect of establishing reciprocal relations between the landless man and the landowner, between property and poverty, between the householder and the houseless,—casting upon one the duty of supervising the conduct and providing for the wants of the other, in some respects similar to the poor law of the present day. "The results of this legislation were likewise, it may be presumed, not very dissimilar, for the improvident and the indolent would endeavor, with the smallest amount of labor, to obtain the largest amount of assistance from the householder who was liable for their support and responsible for their conduct, whilst the householder would as certainly endeavor to obtain the largest amount of labor in return for the cost and responsibility to which he was subject." Again, so long as serfdom and villenage prevailed, whether to be traced to the Norman Conquest or not, there could be no call for any special provision for the destitute. "The persons who might, if free agents and in a destitute state, have been properly relieved out of a common stock, would as serfs or villeins have a claim on their masters, to whom they belonged, and who were bound to provide for them" (Nicholls). As those old ties became more relaxed the change to freedom was accompanied by some evils, and led to a great increase of vagrancy, and from a period commencing before the close of the 14th century there was a stream of legislation on the subject. An Act of 12 Richard II., after providing for labor to persons able to work (see LABOR AND LABOR LAWS, vol. xiv. p. 167), enacts "that beggars impotent to serve shall abide in the cities and towns where they may be dwelling at the time of the proclamation of this statute, and, if the people of the cities and towns will not, or may not suffice to find them, that these, the said beggars, shall draw them to other towns within the hundred, rape, or wapentake, or to the towns where they were born, within forty days after the proclamation made, and there shall continually abide during their lives." This is the first enactment in which the impotent poor are directly named as a separate class, and on that account it has been mistakenly regarded as the origin of the English poor laws; but it makes no provision for their relief, and the chief characteristic of the statute is the fact of its having openly recognized the distinction between "beggars able to labor," and "beggars impotent to serve." Passing over intermediate legislation, by an act passed in 1530,

"directing how aged, poor, and impotent persons compelled to live by alms, shall be ordered, and how vagabonds and beggars shall be punished," justices of the peace were required to give licenses under their seals to such poor, aged, and impotent persons to beg within a certain precinct as they should think to have most need; "and if any do beg out of his precinct he shall be set in the stocks two days and nights; and if any beg without such license he shall be whipped, or else be set in the stocks three days and three nights, with bread and water only. And persons being whole and mighty in body, and able to labor, who shall beg, or be vagrants and not able to account how they get their living, shall be whipped, and sworn to return to the place where they were born, or last dwelt by the space of three years, and there put themselves to labor" (22 Hen. VIII. c. 12).

Six years later an important and very interesting Act was passed reciting that, although it had been ordained that aged, poor, and impotent people should repair to the hundred where they were born or had dwelt for three years before, no provision had been made how they should be ordered at their coming thither, nor how the hundred should be charged for their relief. It was therefore enacted that the mayors, sheriffs, constables, householders, and all other head officers of every city, shire, town, and parish, at the repair and coming thither of such poor creature should most charitably receive them, and all the governors and ministers of every such place should succor, find, and keep them by way of voluntary and charitable alms, as should be thought meet in their discretion, in such wise as none of the poor persons of very necessity should be compelled to go openly in begging, on pain of every parish making default forfeiting 20s. a month. The head officers and churchwardens, or two others of every parish in the realm, were required to gather and procure such voluntary and charitable alms of the good Christian people, by means of boxes every Sunday, holiday, and other festival, in such good and discreet ways as the poor, impotent, lame, feeble, sick, and diseased people, being not able to work, may be provided, holpen, and relieved, so that in no wise none of them be suffered to go openly in begging, and such as be lusty may be kept in continual labor. Every preacher, parson, vicar, and curate, as well in their sermons, collections, bidding of the beads, as in time of confessions, and at the making of the wills or testaments of any persons, at all times, of the year shall exhort, move, stir, and provoke people to be liberal. Certain of the poor people were themselves appointed to collect and gather broken meats and fragments and the refuse drink of every householder in the parish, to be distributed equally among the poor at discretion. The overplus of collections in rich and wealthy parishes was distributable towards the sustentation of other poor parishes. The Act provided that, where the voluntary and unconstrained alms and charity, together with any moneys added or given from any monasteries or persons or bodies, proved insufficient, the officers and inhabitants should not incur the penalty nor be constrained to any contribution other than at their free will, provided that what was collected was justly distributed. Provision was made for duly accounting and for the punishment of embezzlement. Constables, churchwardens, and collectors of alms had, however, allowance for their loss of time and their travelling expenses (27 Hen. VIII. c. 25).

A number of statutes were passed after the dissolution of the monasteries for further providing for the poor and impotent, who had increased in great numbers. Many of these statutes were specially directed against vagrancy, and have been referred to in the article already mentioned, as closely connected with compulsory labor.

At the commencement of the reign of Edward VI. (1547) a statute also affecting laborers and vagrants and dealing very harshly with them (see vol. xiv. p.

168), reciting that there are many maimed and otherwise lamed, sore, aged, and impotent persons which, resorting together and making a number, do fill the streets or highways of divers cities, towns, markets, and fairs, who, if they were separated, might easily be nourished in the towns and places wherein they were born, or have been most abiding for the space of three years, enacted that the mayor, constable, or other head officer of any city, town, or hundred shall see all such idle, impotent, and aged persons, who otherwise cannot be taken for vagabonds, which were born within the said city, town or hundred, or have been most conversant there by the space of three years and now decayed, bestowed and provided for of tenancies, cottages, or other convenient houses to be lodged in, at the cost of the place, there to be relieved and cured by the devotion of good people, and suffer no others to remain and beg there, but shall convey them on horseback, cart, chariot, or otherwise to the next constable, and so from constable to constable, till they be brought to the place where they were born, or most conversant as aforesaid; provided that, if they were not so lame or impotent but that they might do some manner of work, work was to be provided either in common, or place them with such persons as would find them work for meat and drink. For the furtherance of the relief of such as were in "unfeigned misery," the curate of every parish was required on every Sunday and holiday, after reading the gospel of the day, to make (according to such talent as God hath given him) a godly and brief exhortation to his parishioners, moving and exciting them to remember the poor people, and the duty of Christian charity in relieving of them which be their brethren in Christ, born in the same parish, and needing their help. There was a proviso that all leprous and poor bedridden creatures were at liberty to remain in houses appointed for such persons, and for their better relief such persons were allowed to appoint one or two persons for any one such house to gather the alms of all inhabitants within the compass of four miles (1 Edw. VI. c. 3). This statute, however, was of brief duration.

Subsequently, in the same reign, further legislation took place, having for its main object the restraint of vagrancy, providing that every vagabond and beggar being born in any other nation or country should be conveyed from place to place, or to the place or borders next adjoining to his native country or to the nearest port if there was a sea between, there to be kept of the inhabitants until they could be conveyed over, and then at the cost of the inhabitants of the port, if the vagrants had not themselves wherewith to defray the cost. The same statute made provision for children, reciting that many men and women going begging, impotent and lame, and some able enough to labor, carried children about with them, which, being once brought up in idleness, would hardly be brought afterwards to any good kind of labor or service, and authorizing any person to take such child between the ages of five and fourteen to be brought up in any honest labor and occupation till such child, if a woman, attained the age of fifteen or was married, and if a man child until eighteen, if the master so long lived (3 & 4 Edw. VI. c. 16).

Two years later the mayor or head officer of every city, borough, and town corporate, and in every other parish of the country the parson and churchwardens, having in a book as well the names of inhabitants and householders as of needy persons, were required yearly "one holiday in Whitsunweek openly in the church and quickly after divine service to call the householders and inhabitants together and select two or more able persons to gather charitable alms for the relief of the poor, and directing such gatherers the week after their election, when the people are at the church, and have heard God's holy word, to gently ask and demand of every man and woman what they of their charity would be content to give weekly towards the relief of the poor,

and write the result in the book, to gather and distribute the alms weekly to the poor and impotent persons without fraud or covin, favor or affection, in such manner as the most impotent had the most help, and such as could get part of their living to have the less, and by the discretion of the collectors to be put in such labor as they were fit and able to do, but none to go or sit openly a-begging." It is noteworthy that, except a penalty of 20s. imposed on a person refusing the office of gatherer, duties were enforced by ecclesiastical censure. The gatherers were required to account for the money; and if they refused the bishop of the diocese or ordinary was to compel them by censures of the church to account before such persons as he appointed. Further, if any person, being able to further the charitable work, "do obstinately and frowardly refuse to give towards the help of the poor or do wilfully discourage others from so charitable a deed," the parson, vicar, or curate, and churchwardens should "gently exhort him, and if he will not be so persuaded" then on certificate the bishop should send for him "to induce and persuade him by charitable ways and means, and so according to his discretion to take order for the reformation thereof" (5 & 6 Edw. VI. c. 2).

This statute was recognized in part after the accession of Mary, by altering the time of choosing collectors to Christmas and doubling the penalty for refusing to fill the office of collector, and moving wealthy parishes in cities and towns to contribute towards the relief of the poor in the less wealthy parishes. At the same time a material modification of the spirit of earlier legislation was effected by enabling justices to license the poor of parishes having more poor than they could relieve, to go begging into specified parishes, wearing a badge "both on the breast and back of their outermost garment" (2 & 3 P. & M. c. 5).

Early in Elizabeth's reign the spiritual persuasion towards obstinate and froward persons withholding contributions was strengthened by the aid of the civil power, by directing the bishop or ordinary to bind all obstinate persons by recognizance to appear at the next sessions; and then, the charitable and gentle persuasions of the justices failing, the latter could tax the obstinate person in a weekly sum according to good discretion, and in default commit him to jail until payment. A corresponding power was given to deal with collectors refusing to account (5 Eliz. c. 3). A few years later (1572) legislation took a more vigorous turn "for the punishment of vagabonds and for relief of the poor and impotent." The Act 14 Eliz. c. 5, reciting that "all the parts of this realm of England and Wales be presently with rogues, vagabonds, and sturdy beggars exceedingly pestered, by means whereof daily happeneth in the same realm horrible murders, thefts, and other great outrages, to the high displeasure of Almighty God, and to the great annoy of the common weal, and for avoiding confusion by reason of numbers of laws concerning the premises standing in force together," repealed the before-mentioned statutes of 22 Hen. VIII., 3 & 4 Edw. VI., and 5 Eliz. c. 3, and made provision for various matters, "as well for the utter suppressing of the said outrageous enemies to the common weal as for the charitable relieving of the aged and impotent poor people." Persons above fourteen and being rogues, vagabonds, or sturdy beggars, and "taken begging in every part of this realm, or taken vagrant, wandering and misordering themselves," were upon their apprehension to be committed to prison to the next sessions or jail delivery without bail, and on conviction "shall be adjudged to be grievously whipped, and burnt through the gristle of the right ear with a hot iron of the compass of an inch about, manifesting his or her roguish kind of life and his or her punishment received for the same." This judgment was not to be executed if after imprisonment "some honest person, valued at the last subsidy next before that time to five pounds in goods or

twenty shillings in lands, or else some such honest householder as by the justices of the peace of the same county, or two of them, shall be allowed, will of his charity take such offender before the same justices into his service for one whole year," under recognizance to keep this poor person for that period and to bring him, if still living, before the justices at the year's end; on the other hand the pauper departing within the year against the will of his master was to be whipped and burnt as above provided. The offender was absolved from a second punishment for a short time but if after threescore days, and being of the age of eighteen or more, he "do oftsoons fall again to any kind of roguish or vagabond's trade of life," then the said rogue, vagabond, or sturdy beggar, from thenceforth was "to be taken, adjudged, and deemed in all respects as a felon," and should suffer as a felon—subject, however, to like redemption as on the first charge, conditioned for two years' service; but offending a third time he was to "be adjudged a felon" and suffer pains of death and loss of lands and goods as a felon, without allowance or benefit of clergy or sanctuary. Offenders under fourteen were punishable by whipping or stocking as provided by the repealed statutes.

A clause defining persons subject to the above punishment throws a light on the manners of the age, and is, as well as its exceptive provisions, of considerable interest; but, as relating to vagrancy, and only indirectly to the relief of the really poor, it is not given here. It is to be observed, however, that the statute provided that it should be still lawful to masters and governors of hospitals to lodge or harbor impotent or aged persons by way of charity according to their foundation, and to give money in alms as provided by the terms of their foundation. Harsh as was the treatment of rogues, vagabonds, and sturdy beggars, it was not so cruel as the short-lived legislation of the reign of Edward VI. imposing slavery in its worst form on wandering serving men (see vol. xiv. p. 168).

Exceptional provision was made for persons provided with passes and safe conducts, as in former Acts. The statute goes on to say that, "forasmuch as charity would that poor, aged, and impotent persons should as necessarily be provided for as the said rogues, vagabonds, and sturdy beggars repressed," and that the former should have "convenient habitations and abiding places throughout this realm to settle themselves upon, to the end that they nor any of them should hereafter beg or wander about," and enacts that justices of the peace in their different divisions "make diligent research and inquiry of all aged, poor, impotent, and decayed persons born within their said divisions and limits, or which were there dwelling within three years next before this present parliament, which live, or of necessity be compelled to live by alms of the charity of the people that be or shall be abiding within the limits of their commissions and authorities," and to register in a book the names of the poor persons, and devise and appoint meet and convenient places at their discretion "to settle the same poor people for their habitations and abidings, if the parish within the which they shall be found shall not or will not provide for them." The justices were also to number the poor people and "set down what portion the weekly charge towards their relief and sustentation would amount to;" and, that done, the justices, mayors, and other officers should "by their good discretions" tax the inhabitants dwelling within these limits to such weekly charge, and appoint collectors and also overseers of the poor for one year. Much as by a previous statute of 1547, compulsory removal of poor people from parish to parish (except the leprous and bed-ridden), not born or not having dwelt in the place, was provided for. Poor people refusing to "be bestowed in any of the said abiding places, but coveting still to hold on their trade of begging," or afterwards departing, were for the first offence to suffer as rogues or vagabonds in the first degree of punishment,

and for a second offence to suffer the last degree of punishment already mentioned. The provisions as to putting out children of beggars contained in the statute of Edward VI. already noticed were repeated in nearly the same terms, but the age of male children was extended from eighteen to twenty-four for the duration of service.

The Act provided for justices' licenses for poor to beg, ask, and receive relief in other parishes under similar circumstances as badges had been granted under an earlier and repealed statute. The Act also contained many provisions and exceptions as to places and corporate bodies, and any person "able to further the charitable work" contemplated by the statute, and obstinately refusing to give towards the help and relief of the poor, or wilfully discouraging others from so charitable a deed, was to be summoned before justices to abide their order, and on refusal to be committed to jail, and "there to remain until he be contented with their said order, and to perform the same."

There is extant a letter addressed to Lord Burghley by a justice of the peace for Somerset, which shows that the great evils arising from habits of idleness amongst the poor began then to be understood, and strengthens the idea that one great object of the legislative provisions for the poor made about that time was to prevent able-bodied men from remaining unemployed. The writer advocated building houses of correction adjoining jails, to which vagrants, after conviction, should be transported, "to be kept in work, except some person would take any of them into service,"—adding, "I dare presume to say the tenth felony will not be committed that now is" (Strype, *Annals of Church and State*).

In 1576 the statute 14 Eliz. c. 5 was explained and materially extended. "To the intent youth may be accustomed and brought up in labor, and then not like to grow to be idle rogues, and to the intent also that such as be already grown up in idleness, and so rogues at this present, may not have any just excuse in saying that they cannot get any service or work, and that other poor and needy persons being willing to labor may be set on work," it was ordained that within every city and town corporate, by appointment of the mayor and other head officer, and in every other market town or other place where the justices in their general sessions yearly shall think meet, shall be provided a stock of wool, hemp, flax, iron, or other stuff, as that country is most meet for, and being wrought to be delivered to collectors and governors of the poor. Any person refusing to work, or begging, or living idly, or taking such work, spoiling or embezzling it in such wise that after monition given the minister and church-wardens and the collectors and governors think such person not meet to have any more work delivered to him, was to be taken, "in convenient apparel meet for such a body to wear," to the "house of correction" established by the Act, and under the government of overseers of such houses, called censors and wardens, "there to be straitly kept, as well in diet as in work, and also punished from time to time." To the houses of correction were also taken and set on work not only the persons mentioned but also such "as be inhabitants in no parish or taken as rogues, or who had been once punished as rogues, or by reason of the uncertainty of their birth or of their dwelling by the space of three years, or for any other cause, ought to be abiding and kept in the county." An additional clause of the Act, reciting that by the earlier Act of 14 Eliz. no "pain" was incurred by any impotent person who having a competent allowance provided within his parish wandered abroad without license "loitering and begging," enacted that he was to be whipped, and for a second offence to "suffer as a rogue and vagabond" (18 Eliz. c. 3). The "stock" for work and the houses of correction were provided "of all the inhabitants to be taxed;" but, "because

it is to be hoped that many well-disposed persons, understanding the good success which will grow by setting people on work and avoiding of idleness, would from time to time give towards the sustentation and maintenance of that good purpose," persons were empowered during the next twenty years to give lands for the purposes without any license of mortmain. A later Act, reciting that this power to erect hospitals or other abiding and working houses for the poor had not its due effect by reason that no person could erect such house without special license from the crown by letters patent, dispensed with such license for twenty years (39 Eliz. c. 5).

The numerous charities and endowments and foundations of almshouses by will and otherwise of the 16th and 17th centuries, still extant in numerous buildings throughout the country, are illustrations of the spirit of the legislation here referred to. It is not improbable that legislation sometimes prompted the donors, but more probable that such legislation was a reflex of the general disposition prevalent for generations after the ordinary channels of voluntary charity were obstructed.

In 1597 considerable progress was made towards establishing a system of poor laws, not so much by introducing novelties as by entering more specifically into details, and especially by defining the legislation of some twenty years earlier (18 Eliz. c. 3) in the same reign. The appointment of overseers first mentioned in the earlier statute was provided for by enacting that the church-wardens of every parish and four subsidy men or other substantial householders nominated yearly in Easter week by justices should be called overseers of the poor of the same parish. The majority of the overseers were required with the consent of justices to set to work the children of persons unable to maintain them, and also all persons married or single and having no means of maintenance and no ordinary and daily trade of life to get their living by. The taxation weekly or otherwise of inhabitants and occupiers for providing a stock of flax, hemp, wool, thread, iron, and other necessary wares and stuff to set the poor on work, and also competent sums for the necessary relief of the lame, impotent, old, blind poor, unable to work, and the cost of erection, by leave of the lords of manors, of places of habitation on waste or common lands, was gathered according to the ability of the parish (or, if the parish was unable, then of other parishes in the hundred and county), and was enforceable by warrant of distress against everyone refusing to contribute, but with a power of appeal against the cess or tax. Parents and children being of sufficient ability were required to maintain their poor children or parents. Any person whatsoever wandering abroad and begging in any place, by license or without, was punishable as a rogue, with a proviso exempting poor persons asking relief in victuals only in the parishes where they dwelt (39 Eliz. c. 3).

Four years after came "the famous statute" of 1601 (43 Eliz. c. 2) already mentioned, out of which, Dr. Burn observes, "more litigation and a greater amount of revenue have arisen, with consequences more extensive and more serious in their aspect than ever were identified with any other Act of Parliament or system of legislation whatever." It was the permanent establishment of the main provisions of the Act more than their novelty at the time the Act was passed that has fixed it as a kind of epoch in legislation for the maintenance of the poor. The Act re-enacts, verbatim for the most part, the above-mentioned statute of 1597 (39 Eliz. c. 3). The material alterations were defining the ratable property, and extending and defining the family obligation of support, and also the formal apprenticing instead of placing out of children. The Act contains provisions for the rendering of accounts by the overseers.

The foregoing short review of legislation exhibits

the very gradual change by which the maintenance of the poor became much more a temporal than a spiritual concern. So gradual was this change that in some places the law was neglected and in others abused. The material changes in legislation subsequent to the reign of Elizabeth must now be briefly alluded to.

The efforts culminating in the statute of 1601 were not altogether attended with satisfactory results. At the end of eight years the Act 7 James I. c. 4 recited various defects. "Many wilful people finding that they, having children, have some hope to have relief from the parish wherein they dwell, and being able to labor, and thereby to relieve themselves and their families, do nevertheless, run away out of their parishes and leave their families upon the parish." Again, and more prominently, "heretofore divers good and necessary laws and statutes have been made and provided for the creation of houses of correction for the suppressing and punishing of rogues, vagabonds, and other idle, vagrant, and disorderly persons; which laws have not wrought so good effect as was expected, as well for that the said houses of correction have not been built according as was intended, as also for that the said statutes have not been duly and severely put in execution, as by the said statutes were appointed."

It was also convenient that the masters or governors of the houses of correction should have some fit allowance and maintenance "for their travel and care" to be had in the service, and also "for the relieving of such as shall happen to be weak and sick in their custody, and that the subjects of this realm should in no sort be overcharged, to raise up money for stocks to set such on work as shall be committed to their custody," and that there "shall be the more care taken by all such masters of the houses of correction that, when the country hath been at trouble and charge to bring all disorderly persons to their safe keeping, then they shall perform their duties in that behalf." Another grievance related to bastard children chargeable to the parish, of which more below.

The remedy for these and other grievances was putting in execution "all laws and statutes now in force made for the creating and building of houses of correction, and for punishing of rogues, vagabonds, and other wandering and idle persons," and providing restraints in the same direction, and for the efficient discharge of duties of treasurers, constables, and other officers in rendering accounts.

In 1630 a royal commission was issued to inquire into the neglect of the poor laws, and directions given for their enforcement.

By a Commonwealth statute of 1656, reciting that "the number of wandering, idle, loose, dissolute, and disorderly persons is of late much increased by reason of some defects in the laws, and statutes heretofore made and provided for the punishment of rogues, vagabonds, and sturdy beggars (they being seldom taken begging), by means whereof divers robberies, burglaries, thefts, insurrections, and other misdemeanors have been occasioned, all and every idle, loose, and dissolute persons found and taken within the commonwealth of England, vagrant and wandering from their usual place of living or abode, and [who] shall not have such good and sufficient cause or business for such his or their travelling or wandering" as justices of the peace or mayors or other chief officers approved, were adjudged rogues, vagabonds, and sturdy beggars, within the statute 39 Eliz. c. 4, although not found begging; at the same time fiddlers and minstrels were also adjudged rogues, vagabonds, and sturdy beggars; and by a statute of the same year persons having no visible estate, profession, or calling answerable to their rate of living expenses were indictable.

Soon after the Restoration attention was directed to the existing state of the law and some of its defects. In 1662 the statute 13 & 14

James I.

Commonwealth.

Charles II.

Charles II. c. 12 recites that "the necessity, number, and continued increase of the poor, not only within the cities of London and Westminster, with the liberties of each of them, but also through the whole kingdom of England and dominion of Wales, is very great and exceeding burthensome, being occasioned by reason of some defects in the law concerning the settling of the poor, and for want of a due provision for the regulations of relief, and employment in such parishes or places where they are legally settled, which doth enforce many to turn incorrigible rogues, and others to perish for want, together with the neglect of the faithful execution of such laws and statutes as have formerly been made for the apprehending of rogues and vagabonds, and for the good of the poor."

"For remedy whereof and for the preventing the perishing of any of the poor, whether young or old, for want of such supplies as may be necessary," numerous additional provisions were enacted. In the first place, "by reason of some defects in the law, poor people are not restrained from going from one parish to another, and therefore do endeavor to settle themselves in those parishes where there is the best stock, the largest commons or wastes to build cottages, and the most woods for them to burn and destroy, and, when they have consumed it, then to another parish, and at last become rogues and vagabonds, to the great discouragement of parishes to provide stocks, where it is liable to be devoured by strangers." Justices of the peace, upon complaint by the parish officers, within forty days after any such person's coming to settle as before mentioned in any tenement under the yearly value of £10, were empowered by warrant to remove such person to the parish where he was last legally settled either as a native, householder, sojourner, apprentice, or servant for not less than forty days, unless he gave sufficient security for the discharge of the parish.

In this way the law of settlement arose, with its numerous complications and modifications engrafted by subsequent legislation on this its original trunk. The statute of Charles, however, allowed (§ 3) any person "to go into any county, parish, or place to work in the time of harvest, or any time to work at any other work," provided he took with him "a certificate from the minister of the parish and one of the parish officers, that he or they have a dwelling house or place in which he or they inhabit, and have left wife and children or some of them, there (or otherwise, as the condition of the persons shall require), and is declared an inhabitant or inhabitants there." In such case, if the person did not return to his parish when his work was finished, or if he fell sick, it was not "counted a settlement," and he was therefore removable, and wilfully refusing, was punishable as a vagabond by being sent to the house of correction, or to a public workhouse, provision for which and for corporate bodies in relation to the poor in London and Westminster, and places within the so-called bills of mortality, was made at the same time. Funds raised for the relief of the poor in the city of London were, however, previously in the hands of a corporate body for that purpose.

The same statute, reciting that "the inhabitants of the counties of Lancashire, Cheshire, Derbyshire, Yorkshire, Northumberland, the bishopric of Durham, Cumberland, and Westmoreland, and many other counties in England and Wales, by reason of the largeness of the parishes within the same," could not reap the benefit of the Act 43 Eliz., extended the powers of the Act to townships and villages within these counties.

Power was given to justices at quarter sessions, to transport rogues, vagabonds, and sturdy beggars, in some cases with the approval of the privy council, or without such approval, if convicted and adjudged to be incorrigible, to any of the English plantations beyond the seas, "there to be disposed in the usual way of servants for a term not exceeding seven years."

This Act, which, except as to the corporate bodies before mentioned, was limited to three years' duration, was continued by various Acts, and made perpetual in the reign of Anne. One of the Acts continuing the former provisions, and containing some minute provisions affecting settlements, affords strong evidence of want of care of the funds, and even of the frauds practiced by parochial officers. Many inconveniences arose "by reason of the unlimited power of the churchwardens and overseers of the poor, who do frequently upon frivolous pretences (but chiefly for their own private ends) give relief to what persons and number they think fit; and such persons, being entered into the collection bill, do become after that a great charge to the parish, notwithstanding the occasion or pretence of their receiving collection oftentimes ceases, by which means the rates for the poor are daily increased." This grievance was sought to be remedied by means of a register with names and dates, to be examined by the vestry, and those only to be relieved who were allowed by a justice, except in certain urgent cases. The Act mentions more direct frauds. "Many churchwardens and overseers of the poor, and other persons intrusted to receive collections for the poor and other public moneys relating to the churches and parishes whereunto they do belong, do often misspend the said moneys and take the same to their own use, to the great prejudice of such parishes, and the poor and other inhabitants thereof," owing to the law by which persons in any way interested in the funds, as parishioners, although the only persons who could prove the facts, could not give evidence on the trial of actions against the parish officers to recover the misspent money; and therefore parishioners, excepting almsmen, were rendered competent witnesses in such actions (3 Will. & Mary c. 11).

The injurious effects of the restraint placed on the free removal of the laboring classes is evinced by a statute towards the close of the 17th century. To make this intelligible it is necessary to say that by the statute 1 James II. c. 17 (one of the Acts continuing the Act of Charles II.) it was enacted that, as poor persons "at their first coming to a parish do commonly conceal themselves," the forty days continuance in a parish intended by the Act of Charles to make a settlement were to be accounted from the time of the person's delivering a notice in writing of the house of abode and number of the family to the parish officer. Hence persons coming to work under a certificate, on its production, were removed back again, lest they gained a settlement at the end of forty days. The statute now to be noticed recited that, "forasmuch as many poor persons chargeable to the parish, township, or place where they live, merely for want of work, would, in any other place where sufficient employment is to be had, maintain themselves and families without being burthensome to any parish, township, or place, but not being able to give such security as will or may be expected and required upon their coming to settle themselves in any other place, and the certificates that have been usually given in such cases having been oftentimes construed into a notice in handwriting, they are for the most part confined to live in their own parishes, townships, or places, and not permitted to inhabit elsewhere, though their labor is wanted in many other places, where the increase of manufactures would employ more hands." This mischievous result of previous legislation was sought to be avoided by a certificate of acknowledgment of settlement, and then and not before, on becoming chargeable to another parish, the certificated person could be sent back to the parish whence it was brought (8 & 9 Will. III. c. 30). This provision led to additional legislation, complicating the law of settlement. It was not until towards the close of the 18th century that an important inroad on the law relating to the removal of the poor was made by requiring actual chargeability before removal to their place of settlement (35 Geo. III. c. 101); and at the

same time justices were empowered to suspend removal in the case of sickness.

By the statute of William III. (8 & 9 Will. III. c. 30), "to the end that the money raised only for the relief of such as are as well impotent as poor may not be misapplied and consumed by the idle, sturdy, and disorderly beggars," persons receiving parochial relief and their wives and children were required (under the punishment for refusal of imprisonment and whipping, or of having the reliefs abridged or withdrawn) to wear a badge on the shoulder of the right sleeve—that is to say, a large "P" together with the first letter of the name of the parish or place, cut in red or blue cloth; and a penalty was imposed on churchwardens and overseers relieving poor persons not wearing such badge. The provision (a revival of a much earlier law) continued down to 1810, when it was abolished.

In 1744 provision was made reviving rather than introducing a system of magisterial "passes" for passing persons apprehended as rogues and vagabonds to their place of settlement (17 Geo. II. c. 5). Great abuses in conveying persons by passes, attributed to the neglect of this Act, led to its amendment nearly half a century later. Although these statutes fell into disuse they were not finally repealed until after the introduction of the present poor-law system.

In 1722 the system of farming the poor was introduced. By 9 Geo. I. c. 7, "for the greater ease of parishes in the relief of the poor," parish officers with the consent of the parishioners or inhabitants in vestry were authorized to purchase or hire houses, "and to contract with any person or persons for the lodging, keeping, maintaining, and employing any or all such poor in their respective parishes, townships, or places, as shall desire to receive relief or collection from this same parish, and there to keep, maintain, and employ all such poor persons, and take the benefit of the work, labor, and service of any such poor person or persons who shall be kept or maintained in any such house or houses, for the better maintenance and relief of such poor persons who shall be there kept or maintained." Any poor persons refusing to be so lodged were not to be entitled to relief. Small parishes could unite or contract with another parish for the maintenance of the poor.

A few years sufficed to develop the injurious effects of this mode of dealing with the poor, and the accumulated evils of the working of the poor laws led, in 1783, to the passing of the statute 22 Geo. III. c. 83, known as "Gilbert's Act," the principle of which was extensively adopted in subsequent legislation. The Act significantly recited that, notwithstanding the many laws now in being for the relief and employment of the poor, and the great sums of money raised for those persons, their sufferings and distresses are nevertheless very grievous, and by the incapacity, negligence, or misconduct of overseers, the money raised for the relief of the poor is frequently misapplied, and sometimes expended in defraying the charges of litigations about settlements indiscreetly and inadvisably carried on, and also recited the provisions of the 9 Geo. I. c. 7, relating to contracts for the maintenance of the poor, and that such provisions, from the want of proper regulations and management in the poorhouses or workhouses that have been purchased or hired under the authority of the said Act and for want of due inspection and control over the persons who have engaged in those contracts, have not had the desired effect, "but the poor in many places, instead of finding protection and relief, have been much oppressed thereby." "For the remedy of these grievances and inconveniences, and in order to make better and more effectual provision for the relief and employment of the poor, and to introduce a prudent economy in the expenditure of the parish money," much legislative machinery was introduced, which, although not compulsory, was very extensively adopted,

and with many amendments remained on the statute book long after the Poor Law Amendment Act of 1834. Although the Act has now disappeared, having been expressly repealed (as it was by implication previously) in 1871, Gilbert's Act is memorable as having first introduced the representation of the poor by guardians, although not by the present system of election. The Act repealed 9 Geo. I. c. 7, as regarded the farming of the poor where Gilbert's Act was adopted, but agreements for the diet and clothing and work of poor in poorhouses, subsequently termed "houses of industry," were expressly sanctioned. The limits of this article do not admit even of an analysis of this important statute. In many respects a double system of administration sprang up in parishes, single or united, adopting Gilbert's Act, and in parishes not under that Act. In both, the conflict between the administration of relief in and out of the poorhouse arose, and continued from the time of the establishment of places of work whether termed workhouses, poorhouses, or houses of industry, and whether under special local or under general Acts.

In 1795 the 36 Geo. III. c. 23, reciting that a provision of the 9 Geo. I. c. 7, prohibiting relief to persons refusing to go into poorhouses, "has been found to have been and to be inconvenient and oppressive, inasmuch as it often prevents an industrious poor person from receiving such occasional relief as is best suited to the peculiar case of such poor person, and inasmuch as in certain cases it holds out conditions of relief injurious to the comfort and domestic situation and happiness of such poor persons," gave power to the overseers, with the approbation of the parishioners in vestry or of a justice of the peace, to distribute and pay collection and relief to industrious poor persons at their homes under certain circumstances of temporary illness or distress, and in certain cases respecting such poor persons or their families, or respecting the situation, health, or condition of any poorhouse, in any place wherein houses shall have been hired or built and a contract made with any person for lodging, maintaining, and employing the poor, although the poor persons refused to be so lodged and maintained. Justices had besides a "just and proper discretion" for special cause stated in writing to order relief for a time not exceeding a month. This Act, however, did not extend to places where houses of industry or other places were provided under Gilbert's Act or under any special Act.

The evils arising from farming the poor under the 9 Geo. I. c. 7 nevertheless continued in places not adopting Gilbert's Act. Contractors were often non-resident and not of sufficient responsibility to insure performance of their undertaking. In 1805 these special defects were sought to be met by requiring residence, sureties, and the approval of the contract by two justices (45 Geo. III. c. 54). But these remedies did not touch the whole extent of the evil of neglect of the poor. The laws for regulating workhouses and poorhouses were found deficient and ineffectual, especially when the poor in such houses were "afflicted with contagious or infectious diseases, in which cases particular attention to their lodging, diet, clothing, bedding, and medicine is requisite." A statute passed in 1790 (30 Geo. III. c. 49) enabled justices, or medical men authorized by them or the officiating clergyman of the parish, to visit workhouses, and on finding cause for complaint to certify to the quarter sessions, and thereupon the court was authorized to make orders for removing any cause of complaint; and, moreover, without waiting for this dilatory process, if on the visitation any of the poor were found afflicted with any contagious or infectious disease, or in want of immediate medical or other assistance, or of sufficient food, or requiring separation or removal, justices of the division were empowered to make an order for immediate relief according to the

Act.

nature of the application. There can be no doubt that the legislation of five years later already noticed (36 Geo. III. c. 23) had reference to cases of this kind as well as to the hardships inherent in the rigid application of the practice of confining relief to the workhouse.

In 1819 an Act (59 Geo. III. c. 12) was passed, the result of the report of a committee appointed two years before, containing a variety of provisions relating to the poor, empowering the establishment of select vestries "for the concerns of the poor" and regulating their proceedings. Where these were established overseers were prohibited from giving relief other than that ordered by the vestries, except temporary relief in cases of sudden emergency or urgent necessity. Justices had the power, as under earlier provisions, to order temporary relief in such cases, but they were prohibited from ordering relief in parishes where select vestries were established or in which the relief of the poor was under the management of guardians, governors, or directors, unless relief had been refused by such bodies.

An amelioration of the harsher features of the law, relating to vagrancy, are found in the legislation of the 18th and early part of the 19th century. In early times, as has been pointed out legislation affecting labor and vagrancy was blended. Very gradually labor was left to run a freer course. Provisions as to vagrancy and mendicity, including stringent laws in relation to constructive "sturdy beggars," "rogues," and "vagabonds," still formed a prominent feature of poor-law legislation.

In 1713 an Act was passed for reducing the laws relating to rogues, vagabonds, sturdy beggars, and vagrants into one Act, and for more effectually punishing them and sending them to their homes, the manner of conveying them including whipping in every county through which they passed (12 Anne, st. 2, c. 23). This Act was in turn repealed in 1740; and the substituted Consolidation Act (13 Geo. II. c. 24), embracing a variety of provisions, made a distinction between idle and disorderly persons, rogues and vagabonds, and incorrigible rogues. Four years later a statute reciting that the "number of rogues, vagabonds, beggars, and other idle and disorderly persons daily increases, to the great scandal, loss, and annoyance of the kingdom," deals with a great variety of offences, continuing the rough classification already mentioned, and including among "idle and disorderly persons" punishable with hard labor in the house of correction "all persons who shall run away and leave their wives or children to the parish" and "all persons who shall unlawfully return to the parish or place from whence they have been legally removed by order of justices, without bringing a certificate," and also "all persons who, not having wherewith to maintain themselves, live idly without employment and refuse to work for the usual and common wages given to other laborers on the like work, in the parishes or places where they then are," and also all persons begging alms (17 Geo. II. c. 5).

The laws relating to idle and disorderly persons, rogues and vagabonds, incorrigible rogues, and other vagrants in England were again consolidated and amended in 1822 (3 Geo. IV. c. 40), but the Act being temporary and requiring amendment, was superseded two years later by the present Act, 5 Geo. IV. c. 83, commonly spoken of as the Vagrant Act, which with some additions and amendments includes the law relating to mendicity and some provisions concerning persons deserting or neglecting to support their families. Mendicity in the popular sense is now considered as appertaining to police rather than to poor laws. It must suffice here to note the change from former inhuman laws denoted by the fact that corporal punishment is confined by the Vagrant Act

to the permissive infliction of whipping on male persons imprisoned as incorrigible rogues.

The misdoings of the "vagrant train," so often paraded by statute and so severely treated in former times, seem to have been trifling compared with the iniquities of some of those engaged in the administration of poor-law relief. In 1769 it was found necessary to prevent churchwardens and overseers from wilfully and knowingly making payments to or for the use of the poor in base and counterfeit money (9 Geo. III. c. 37). For this heinous offence a penalty limited to twenty shillings was imposed. The curious may compare this mild punishment with that inflicted on a wanderer from his home; for as recently as 1816 it was thought right to declare that it should not be lawful for any governor, guardian, or master of any house of industry or workhouse on any pretence to chain or confine by chains or manacles any poor person of sane mind, a provision significant of what passed within the walls by its prohibition as well as by the limitation.

Such were the most salient features of the legislation respecting the relief of the poor previous to the reform of parliament itself in 1832.

It had long been seen that there was something wrong which legislation had failed to set right. Sir Matthew Hale framed a scheme which was written soon after the middle of the 17th century, although not printed until after his death. The chief feature of his plan was "that the justices of the peace at the quarter sessions do set out and distribute the parishes in their several counties into several divisions, in each of which there may be a workhouse for the common use of the respective divisions wherein they are respectively placed,—to wit, one, two, three, four, five, or six parishes to a workhouse according to the greatness or smallness and accomodation of the several parishes," and that providing "a stock" for work in and out of the workhouses should be made compulsory. His views are thus stated:

"At this day, it seems to me that the English nation is more deficient in their prudent provision for the poor than any other Christian state In some other countries a beggar is a rare sight. Those that are unable to maintain themselves by age or impotency are relieved. And those that are able to supply their wants by their labor are furnished with employments suitable to their condition. And by this means there is not only a good and orderly education and a decent face of the public, but the more populous the state or country is the richer and the more wealthy it is. But with us in England, for want of a due regulation of things, the more populous we are the poorer we are; so that wherein the strength and wealth of a kingdom consists renders us the weaker and the poorer; and, which is yet worse poor families which daily multiply in the kingdom, for want of a due order for their employment in an honest course of life, whereby they may gain subsistence for them and their children, do unavoidably bring up their children either in a trade of begging or stealing or such other idle course, which again they propagate over to their children; and so there is a successive multiplication of hurtful or at least unprofitable people, neither capable of discipline nor beneficial employment.

He further remarks that the continuance of the evils he depicted "must in time prodigiously increase and overgrow the whole face of the kingdom, and eat out the heart of it." In lamenting the want of an industrious education he observes that a "man that has been bred up in the trade of begging will never, unless compelled, fall to industry; and on the other side, it is a wonderful necessity indeed that shall bring one bred up in civility or industry to beg." Almost all subsequent schemes looked up to Hale as their model; but all either were not accepted or did not succeed, although in some of the legislation of the 18th century imperfect attempts seem to have been made in this direction. Among other schemes Sir Josiah Child, in the reign of Charles II., who speaks of the poor in England having always been "in a most sad and

Irregularities of poor-law officers.

Evils and suggested remedies.

wretched condition," proposed to abolish all settlements and receive every poor person that applied to incorporated societies or "fathers of the poor." John Cary, writing about 1700, having for the burden of his tract, and the cure of existing evils, to "provide work for those who are willing, and force them to work that are able," makes some pithy remarks.

"He that walks the streets of London, and observes the fatigues used by the beggars to make themselves seem objects of charity, must conclude that they take more pains than an honest man doth at his trade, and yet seem not to get bread to eat. Beggary is now become an art or mystery, to which children are brought up from their cradles. Anything that may move compassion is made a livelihood, a sore leg or arm, or for want thereof a pretended one. The tricks and devices I have observed to be used by those people have often made me think that those parts, if better employed, might be made useful to the nation." "Licenses for alehouses were at first granted for good ends, not to draw men aside from their labor by games and sports, but to support and refresh them under it; whereas alehouses are now encouraged to promote the income of excise,—not considering withal that the labor of each man, if well employed, whilst he sits in an alehouse, would be worth much more to the nation than the excise he pays." "Our laws to set the poor at work are short and defective, tending rather to maintain them so than to give them to a better way of living. 'Tis true, those laws design well; but, consisting only in generals, and not reducing things to practicable methods, they fall short of answering their ends, and thereby render the poor more bold when they know the parish officers are bound either to provide them work or to give them maintenance."

In 1735 Mr. Hay, a member of the House of Commons, introduced a bill, which, however, was not passed, appointing guardians of a district, chosen by divers occupiers out of a list of persons qualified by estate in land, with power to purchase land, and build and furnish workhouses, and provide stock to set the poor to work, to be paid for by rate,—"every person to be deemed to be legally settled where he continued a year without being chargeable, and if he gained no such settlement then at the place of his birth, and if not born in the kingdom then where he should happen to want relief,"—parochial settlement to be abolished, and a county settlement substituted.

In 1753 bills were introduced into parliament by the earl of Hillsborough and Sir Richard Lloyd, but neither was passed. Lord Hillsborough proposed to repeal all existing Acts, re-enacting much, but getting rid of the notion of settlements and removals, and establishing a county board as governors of the poor with officers to carry out their by-laws, and hospitals for the impotent and the aged and their children, and for no other kind of poor. In the same year Fielding printed *A Proposal for making an effectual Provision for the Poor, for amending their Morals, and for rendering them useful Members of the Society*. His plan embraced county houses of correction, and places of work, maintenance, and punishment, including a "fasting room." It may be regarded as supplementary to schemes of the same period. Although all that fell from this author is worthy of attention, his plan cannot be examined closely here; but what he says of the state of things at the period, evidently the result of his daily observations as a magistrate and inhabitant of Westminster, is too striking to be passed over.

"That the poor are a very great burden and even a nuisance to the kingdom, that the laws for relieving their distress and restraining their vices have not answered their purposes, and that they are at present very ill provided for and much worse governed are truths which every man will acknowledge. Every person who hath any property must feel the weight of that tax which is levied for the use of the poor; and every person who hath any understanding must see how absurdly it is applied. So very useless, indeed, is the heavy tax, and so wretched its disposition, that it is a question whether the poor or rich are actually more dissatisfied; since the plunder of the one serves so little to the real advantage of the other. For while a million yearly is raised among the rich many of the poor are starved; many more languish in want and misery; of the

rest, numbers are found begging or pilfering in the streets to-day, and to-morrow are locked up in jails and bridewells. If we were to make a progress through the outskirts of the metropolis, and look into the habitations of the poor, we should there behold such pictures of human misery as must move the compassion of every heart that deserves the name of human. What indeed must be his composition who could see whole families in want of every necessary of life, oppressed with hunger, cold, nakedness and filth, and with diseases the certain consequence of all these! The sufferings indeed of the poor are less known than their misdeeds; and therefore we are less apt to pity them. They starve, and freeze, and rot among themselves; but they beg, and steal, and rob among their betters. There is not a parish in the liberty of Westminster which doth not swarm all day with beggars and all night with thieves."

The observations of Dr. Burn, a name known to every one who has considered the poor laws, whether as legislator, magistrate or lawyer, followed in 1764. Although the suggestions and observations in his *History of the Poor Laws* are worthy of the highest attention to any one entering into an historical retrospect, it must suffice here to say that the result of his experience and knowledge was that the laws then in force should "stand as to the main" but be rectified on two points—begging and the management of the poor by overseers. Dr. Burn says:

"But how shall begging be restrained? which by a kind of prescriptive claim hath so long been accustomed to triumph above the laws. All sorts of severities, it appears, have been enacted against vagrants; and yet they wander still. Nevertheless, one would hope the disease is not past all remedy. If it is, let us cease the unequal contention, and submissively give up our fortunes to the next that comes with a pass, and tells us a justice of the peace hath so ordered it; but let beggars and vagrants be doing. There is one infallible way to put an end to all this, and the easiest in the world, which consists merely in a non-feasance. Give them nothing. If none were to give, none would beg; and the whole mystery and craft would be at an end in a fortnight. Let the laws continue if you please to apprehend and punish the mendicants; but let something also be done effectually against those who encourage them. If the principal is punished, it is not reasonable the accessory should go free. In order to which, let all who relieve a common beggar be subject to a penalty."

As to the other "fundamental defect," as Dr. Burn styles the leaving the management of the poor to overseers, the position of overseers and their action are so admirably painted, and the description so applicable to the mode of administration down to the reform of 1834, that the observations, written in a happy strain of irony, must be inserted.

"As to overseers of the poor, it is true the law provides that they shall be substantial householders. But many a man may be a substantial householder who is not fit to be an overseer of the poor. And in fact the office goes by rotation from one householder to another—some perhaps tenants at rack rent, whose lease expires the next year, others ignorant and unexperienced, others not willing to charge themselves to disoblige their neighbors; and all of them wanting to get over the office with as little trouble to themselves as possible; and if any, wiser than the rest, projects anything for the common good his office expires at the end of the year and his labor is frustrated, and in practice the office of an overseer of the poor seems to be understood to be this: To keep an extraordinary look-out to prevent persons coming to inhabit without certificates, and to fly to the justices to remove them; and if a man brings a certificate then to caution all the inhabitants not to let him a farm of £10 a year, and to take care to keep him out of all parish offices; to warn them, if they will hire servants, to hire them half-yearly or by the month, by the week or by the day, rather than by any way that shall give them a settlement, or if they do hire them for a year then to endeavor to pick a quarrel with them before the year's end, and so to get rid of them. To maintain their poor as cheap as possibly they can; at all events not to lay out two-pence in prospect of any future good, but only to serve the present necessity; to bargain with some sturdy person to take them by the lump, who yet is not intended to take them, but to hang over them *in terrorem* if they shall complain to the justices for want of maintenance. To send others out into the country a begging (for why cannot they go as well as others they will mention, who are less able in body?) and

the feeblest they are the more profitable will be their peregination. To bind out poor children apprentices, no matter to whom or to what trade, but to take especial care that the master live in another parish. To move heaven and earth if any dispute happens about a settlement, and in that particular to invert the general rule, and stick at no expense. To pull down cottages. To drive out as many inhabitants and admit as few as possibly they can; that is to depopulate the parish in order to lessen the poor rate. To be generous, indeed, sometimes, in giving a portion with the mother of a bastard child to the reputed father, on the condition that he will marry her; or with a poor widow (for why should she be deprived of the comforts of matrimony?)—always provided that the husband is settled elsewhere. Or if a poor man with a large family appears to be industrious they will charitably assist him in taking a farm in some neighboring parish, and give him £10 to pay his first year's rent with; and if any of their poor has a mercantile genius they will purchase for him a box, with pins, needles, laces, buckles and such like wares, and send him abroad in the quality of a petty chapman, with the profits whereof, and a moderate knack of stealing, he can decently support himself, and educate his children in the same industrious way. But to see that the poor shall resort to church, and bring their children there to be instructed; to contract with a master that he shall procure his apprentice at proper times to be taught to read and write; to provide a stock of materials to set the poor on work, to see the aged and impotent comfortably sustained, the sick healed, and all of them clothed with neatness and decency—these and such like it is to be feared are not so generally regarded as the laws intended and the necessity of the case requires."

Dr. Burn's remedy was not to abolish overseers altogether, but, that while they or a permanent overseer should collect the rate, a general superintendent over a certain number of parishes should be appointed by the justices at sessions, and the disposal of the rate directed accordingly.

How far the criticism and suggestions made, from those of Sir Matthew Hale downwards from time to time, influenced the legislation already indicated of the 18th century and the early part of the 19th, it is impracticable to discover. One thing is certain, that evils grew apace: ratepayers on the one hand, the poor on the other, political economists and philanthropists, magistrates and jurists, and observers of every kind were dissatisfied. For the general state of the poor in the beginning of the 19th century as presented to the accurately observant eye and ear of our English Juvenal, we glean more from his *Borough* than from a pile of statistics. Of the poor who were chargeable to the parish Crabbe says:

"To the most we give
A weekly dole, and at their homes they live."

Of the workhouse or house of industry, "the pauper palace which they hate to see," he speaks mournfully. In prose he wrote of the poor who "must be considered in every place as a large and interesting portion of its inhabitants," condemning the workhouse system, alike the pauper palace and the house rented for the poor—the

"House that holds the parish poor,
Whose walls of mud scarce bear the broken door."

A closer examination of the system of maintaining the poor than could be obtained by casual visitors, or even constant residents having no special duty to examine or inquire, showed, in full accord with the public criticism already examined, and in spite of it, that the fund which the famous statute of Elizabeth directed to be employed in setting to work children and persons capable of labor, but using no daily trade, and in the necessary relief of the impotent, was by degrees applied to purposes opposed to the letter and still more to the spirit of that law, and destructive to the morals of the most numerous class and to the welfare of all. The great source of abuse was the relief afforded out of the workhouse to able-bodied persons,—a class never intended by the legislation as fit objects. The description of relief was also very objectionable. Its most usual form was that of relieving the applicants

either wholly or partially from the expense of obtaining house room. Partial relief from that expense was given or professed to be given by exempting the occupants of a cottage or apartment from the payment of rates on the ground of poverty, and in a great number of cases by paying the rent out of the parish fund. Relief afforded in money to the able-bodied on their own account or on that of their families was still more prevalent. This was generally effected by one of the five following expedients: (1) relief without labor, (2) the allowance system, (3) the roundsman system, (4) parish employment, (5) the labor-rate system. (1) The relief without labor was by the parish giving to those who were or professed to be without employment a daily or weekly sum, without requiring from the applicant any labor. (2) "Allowance" sometimes comprehended all parochial relief afforded to those who were employed by individuals at the average rate of wages of the district, and was sometimes confined to the relief which a person so employed obtained on account of his children, in that case any relief obtained on his own account being termed "payment of wages out of rates." In some places allowance was given only occasionally or to meet occasional wants, for instance, to buy clothing or food or to pay the rent of a cottage or apartment. Sometimes the income of the poor was regulated by the name of "scales"—giving in money the price of so many loaves of bread or of a specific measure of flour, according to the number of the family. (3) The roundsman (or, as it was sometimes termed, the billet, or ticket, or item) system was the parish paying the occupiers of property to employ the applicants for relief at a rate of wages fixed by the parish, and depending, not on the services but on the wants of the applicants, the employer being repaid out of the poor rate all that he advanced in wages beyond a certain sum. According to this plan the parish in general made some agreement with a farmer to sell to him the labor of one or more paupers at a certain price, paying to the pauper out of the parish funds the difference between that price and the allowance which the scale, according to the price of bread and the number of his family, awarded to him. It received the local name of billet or ticket system from the ticket signed by the overseer which the pauper in general carried to the farmer as a warrant for his being employed, and afterwards took back to the overseer, signed by the farmer, as a proof that he had fulfilled the conditions of relief. In other cases the parish contracted with a person to have some work performed for him by the paupers, at a given price, the parish paying the paupers. In many places the roundsman system was carried out by means of an auction, all the unemployed men being put up to sale periodically, sometimes monthly or weekly, at prices varying according to the time of year, the old and infirm selling for less than the able-bodied. (4) As for parish employment, although work is made by the statute of Elizabeth a condition precedent to relief otherwise than in the case of the impotent, and it is a duty of the parish officers to provide it, payment by them for work was the most unusual form in which relief was administered. Scarcely more than one-twentieth part of the sum yearly expended for the relief of the poor at the period immediately preceding the inquiry that led to the amendment of the law in 1834 was paid for work, including work on the roads and in the workhouses. This was easily accounted for "by many causes, including the trouble and difficulty attendant upon superintendence on the part of parish officers." (5) An agreement among the ratepayers that each of them should employ and pay out of his own money a certain number of the laborers settled in the parish, in proportion not to his real demand for labor but to his rental or to his contribution to the rates, or to the number of horses that he kept for tillage, or to the

Enumeration and classification of evils.

number of acres that he occupied, or to some other fixed standard, has been denominated the labor-rate system. This system was generally enforced by an additional voluntary rate on those who did not employ their full proportion.

As illustrating the difficulties attendant upon providing for the poor, a temporary Act passed in 1832, which has disappeared from the statute book (as founded on vicious notions), may be noticed, applying to parishes where the poor rates exceeded 5d. in the pound. It recited that, notwithstanding the many laws in force for the relief and employment of the poor, many able-bodied laborers are frequently entirely destitute of work or unprofitably employed, and in many instances receive insufficient allowance for their support from the poor rates, and "the mode of providing employment for the poor which may be expedient in some parishes may be inexpedient in others, and it may therefore be desirable to extend the powers of parish vestries in order that such a course may be pursued as may be best adapted to the peculiar circumstances of each parish," and enabled vestries (without interfering with Gilbert's Act), with the approval of justices at petty sessions, to make special agreements solely for the purpose of employing or relieving the poor of the parish.

The following table exhibits the growth of the poor rate from the middle of the last century to a date immediately preceding the reforms effected in 1834 :

Years.	Estimated Population of England and Wales.	Expended on the Relief of the Poor.	Per Head of the Population.	
			s.	d.
1750	6,467,000	689,000	2	2
1760	6,736,000	965,000	3	0
1770	7,428,000	1,306,000	3	6
1780	7,953,000	1,774,000	4	5
1790	8,675,000	2,567,000	5	11
1800	9,140,000	3,861,000	8	5
1810	10,370,000	5,407,000	10	3
